Revision Summary – For Amec Foster Wheeler Report PS112/RP/020

Rev	Date	Author	Comments
R00	March 2, 2017	Amec Foster Wheeler Staff	Initial issue of report addressing OPG comments on PSR2 Law, Regulation, Code and Standard reviews.

EXECUTIVE SUMMARY

Ontario Power Generation (OPG) is performing a Periodic Safety Review (PSR) to support the possibility of continued operation of Pickering Nuclear Generating Station (NGS) beyond 2020. The PSR (referred to as "PSR2") is a subsequent PSR building on the review basis of earlier OPG Integrated Safety Reviews and other associated assessments. The PSR2 scope and methodology are described in the Pickering PSR2 Basis Document [1].

PSR2 will support and complement the licence renewal application for Pickering NGS going forward. Fifteen Safety Factors will be assessed as part of the PSR. The purpose of Safety Factor reviews is to confirm that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

- Assessing compliance against "Review Tasks" identified in the PSR2 Basis Document [1], which were derived from Canadian Nuclear Safety Commission (CNSC) REGDOC-2.3.3 [2] and International Atomic Energy Agency (IAEA) SSG-25 [3];

- Documenting assessments against applicable modern Laws, Regulations, Codes and Standards (L/R/C/Ss) (as defined in Reference [1]); and

- Reviewing the effectiveness of applicable OPG Nuclear Programs that support the above assessments, through review of audit and self-assessment results.

The process to identify the modern L/R/C/Ss that are applicable to the PSR2 Assessment Basis involved first creating a broad list from multiple sources (potential candidate L/R/C/Ss) and then filtering it to identify those that are most significant, and that are applicable to the PSR2 scope. The identification and selection criteria are detailed in the PSR2 Basis Document [1]. The result of the identification and selection process was a set of modern L/R/C/Ss that became part of the "PSR2 Assessment Basis". This report provides the reviews of L/R/C/Ss that are required to address PSR2 Safety Factors 1 (Plant Design), 5 (Deterministic Safety Analysis), 6 (Probabilistic Safety Assessment) and 7 (Hazard Analysis). As noted in Section 2.0, reviews of several L/R/C/Ss applicable to other Safety Factors were provided in References [4], [5] and [6] and findings from these reviews are not duplicated in this report. There is also some overlap with other Safety Factors for a number of L/R/C/Ss considered, as outlined in Table 1 in Section 2.0 of this report.

The summary of findings documented in Appendix B of this report is as follows:

- CSA N285.0-12, "General Requirements For Pressure-Retaining Systems and Components in CANDU Nuclear Power Plants": There are two gaps associated with Safety Factor 1.

- CSA N293-12, "Fire Protection for Nuclear Power Plants": There are three gaps associated with Safety Factor 1.

- CNSC REGDOC-2.4.1 (2014), "Deterministic Safety Analysis": There are two gaps associated with Safety Factor 5.

- CNSC REGDOC-2.4.2 (2014), "Probabilistic Safety Assessment (PSA) for Nuclear Power Plants": There is one gap associated with Safety Factor 6.

- CSA N287.1-14, "General Requirements for Concrete Containment Structures for Nuclear Power Plants": No gaps.

- CSA N287.3-14, "Design Requirements for Concrete Containment Structures for Nuclear Power Plants": No gaps.

- CSA N287.5-11, "Examination and Testing Requirements for Concrete Containment Structures for Nuclear Power Plants": There is one gap associated with Safety Factor 1.

- CSA N290.0-11, "General requirements for Safety Systems of Nuclear Power Plants": There are three gaps associated with Safety Factor 1.

- CSA N290.1-13, "Requirements for the Shutdown Systems of Nuclear Power Plants": There is one gap associated with Safety Factor 1.

- CSA N290.2-11, "Requirements for Emergency Core Cooling Systems of Nuclear Power Plants": There are two gaps associated with Safety Factor 1.

- CSA N290.3-11, "Requirements for the Containment System of Nuclear Power Plants": There is one gap associated with Safety Factor 1.

- CSA N290.4-11, "Requirements for Reactor Control Systems of Nuclear Power Plants": There is one gap associated with Safety Factor 1.

- CSA N290.5-06, "Requirements for Electrical Power and Instrument Air Systems of CANDU Nuclear Power Plants": There is one gap associated with Safety Factor 1.

- CSA N290.6-09, "Requirements for Monitoring and Display of Nuclear Power Plant Safety Functions in the Event of an Accident": No gaps.

- CSA N290.11-13, "Requirements for Reactor Heat Removal Capability during Outage of Nuclear Power Plants": There are three gaps associated with Safety Factor 1.

- CSA N290.14-15, "Qualification of Digital Hardware and Software for Use in Instrumentation and Control Applications for Nuclear Power Plants": There is one gap associated with Safety Factor 1.

- CSA N291-15, "Requirements for Safety-related Structures for Nuclear Power Plants": There are three CSA N291-15 gaps associated with Safety Factor 1. There is also one PSR2 gap for CSA N291-15 associated with Safety Factor 4 which is identified as a PSR2 gap in OPG Report P-REP-03680-00024 R000, "Pickering 5-8 Continued Operations Plan Review in Support of PNGS Periodic Safety Review 2 (PSR2)" [7]. Therefore, a duplicate gap has not been created under CSA N291-15.

- CSA N285.6 Series-12, "Material Standards for Reactor Components for CANDU Nuclear Power Plants": No gaps.

- ASME B31.1 (2014), "Power Piping": No gaps.

- ASME BPVC (2015), "Boiler and Pressure Vessel Code": No gaps.

- CSA B51-14, "Boiler, Pressure Vessel, and Pressure Piping Code": No gaps.

- NFPA 20 (2016), "Standard for the Installation of Stationary Pumps for Fire Protection": No gaps.

- NFPA 24 (2016), "Standard for the Installation of Private Fire Service Mains and Their Appurtenances": There are two gaps associated with Safety Factor 1.

- CNSC REGDOC-2.5.2 (2014), "Design of Reactor Facilities: Nuclear Power Plants": There are eight gaps associated with Safety Factor 1, one gap associated with Safety Factor 5, and one gap associated with Safety Factor 6.

- CNSC G-144 (2006), "Trip Parameter Acceptance Criteria for the Safety Analysis of CANDU Nuclear Power Plants": No gaps.

- CNSC G-149 (2000), "Computer Programs Used in Design and Safety Analyses of Nuclear Power Plants and Research Reactors": No gaps.

- CNSC R-77 (1987), "Overpressure Protection Requirements for Primary Heat Transport Systems in CANDU Power Reactors Fitted with Two Shutdown Systems": No gaps.

- CSA N288.2-14, "Guidelines for Calculating Radiological Consequences to the Public from a Release of Airborne Radioactive Material for Nuclear Reactor Accidents": There is one gap associated with Safety Factor 5.

- CSA N290.7-14, "Cyber-Security for Nuclear Power Plants and Small Reactor Facilities": The gap analysis, N-REP-69000-10003 R000, "Gap Analysis Between CSA N290.7-14 Cyber Security Requirements for Nuclear Power Plants and Small Reactor Facilities" [8] and implementation plan for N290.7-14 was accepted by the CNSC. For reasons of security and confidentiality, the findings of the gap analysis for N290.7-14 will not be discussed in PSR2.

- NBCC (2010), "National Building Code of Canada": No gaps.

- NFCC (2010), "National Fire Code of Canada": There is one gap associated with Safety Factor 1. This issue is identified as a PSR2 gap in OPG Report P-REP-03680-00024 R000, "Pickering 5-8 Continued Operations Plan Review in Support of PNGS Periodic Safety Review 2" [7]. Therefore, a duplicate gap under NFCC (2010) has not been created.

- CSA N290.8-15, "Technical Specification Requirements for Nuclear Power Plant Components": There is one gap associated with Safety Factor 1.

Details of the reviews can be found in Table 2 and Appendix B of this report.

TABLE OF CONTENTS

LIST OF TABLES

1.0 INTRODUCTION

Ontario Power Generation (OPG) is performing a Periodic Safety Review (PSR) to support the possibility of continued operation of Pickering Nuclear Generating Station (NGS) beyond 2020.[1] A comprehensive Integrated Safety Review (ISR) was completed for Pickering Units 5 through 8 in 2009 in support of refurbishment and continued operation. Pickering Units 1,4 integrated safety assessments were also performed for Pickering A Return to Service (PARTS) in support of approval to restart Units 1 and 4. In addition to these Pickering-specific studies, the 2013 Darlington ISR performed extensive code and standard reviews that were updated in relation to the versions that were assessed in the 2009 Pickering B ISR.[2] These previous ISRs are considered to constitute the first PSR completed for Pickering (referred to as "PSR1"). The current PSR (referred to as "PSR2") is a subsequent PSR building on the basis of earlier OPG integrated safety assessments through review of the various studies, assessments and licence renewals performed since PSR1. The PSR2 scope and methodology are described in the Pickering PSR2 Basis Document [1].

PSR2 will support and complement the licence renewal application for Pickering NGS going forward. Fifteen Safety Factors will be assessed as part of the PSR. The purpose of Safety Factor reviews is to confirm that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

- Assessing compliance against "Review Tasks" identified in the PSR2 Basis Document [1], which were derived from Canadian Nuclear Safety Commission (CNSC) REGDOC-2.3.3 [2] and International Atomic Energy Agency (IAEA) SSG-25 [3];

- Documenting assessments against applicable modern Laws, Regulations, Codes and Standards (L/R/C/Ss) (as defined in Reference [1]); and

- Reviewing the effectiveness of applicable OPG Nuclear Programs that support the above assessments, through review of audit and self-assessment results.

The process to identify the modern L/R/C/Ss that are applicable to the PSR2 Assessment Basis involved first creating a broad list from multiple sources (potential candidate L/R/C/Ss) and then filtering it to identify those that are most significant, and

---

1 Currently, Pickering Units 5-8 are approved to operate to 247,000 Effective Full Power Hours. This operation limit is expected to be reached on some units in 2020. For the purposes of PSR2, OPG assumes operation of Pickering NGS for up to eight additional years, from 2020 until 2028. OPG will make a decision regarding the permanent shut down dates for the six reactors following the performance of a technical evaluation that will include PSR2, and will communicate it to the CNSC as required by the current Power Reactor Operating Licence (PROL).

2 Much of the compliance assessment and evaluation of Safety Factor health for the Darlington ISR is based on programs and practices that apply across OPG's nuclear operations. As a result, where Pickering is confirmed to follow the same nuclear programs and practices as were assessed for Darlington, the Darlington ISR programmatic conclusions are applicable to Pickering.

that are applicable to the PSR2 scope. The identification and selection criteria are detailed in the PSR2 Basis Document [1]. The result of the identification and selection process was a set of modern Laws, Regulations, Codes and Standards that became part of the "PSR2 Assessment Basis". The PSR2 Basis Document also identifies the modern version and date of the L/R/C/S and the type of review that will be completed in PSR2. The types of review are explained in Section 2.0 below.

This report provides the reviews of L/R/C/Ss with content applicable to Safety Factors 1 (Plant Design), 5 (Deterministic Safety Analysis), 6 (Probabilistic Safety Assessment) and 7 (Hazard Analysis). As noted in Section 2.0, reviews of several L/R/C/Ss applicable to other Safety Factors were provided in References [4], [5] and [6] and findings from these reviews are not duplicated in this report. There is also some overlap with other Safety Factors for a number of L/R/C/Ss considered, as outlined in Table 1 in Section 2.0 of this report.

As outlined in IAEA SSG-25 [3], the objectives of these Safety Factor reviews are as follows:

- The objective of the review of Safety Factor 1 is to determine the adequacy of the design of the nuclear power plant and its documentation by assessment against the current licensing basis and national and international standards, requirements and practices.

- The objective of the review of Safety Factor 5 is to determine to what extent the existing Deterministic Safety Analysis (DSA) is complete and remains valid when the following aspects have been taken into account:

    - The actual plant design, including all modifications of Structures, Systems and Components (SSCs) since the last update of the safety analysis report or PSR1;

    - Current operating modes and fuel management;

    - The actual condition of SSCs important to safety and their predicted state at the end of the period covered by the PSR2;

    - The use of modern validated computer codes;

    - Current deterministic methods;

    - Current safety standards and knowledge (including research and development outcomes); and

    - The existence and adequacy of safety margins.

- The objective of the review of Safety Factor 6 is to determine:
    - The extent to which the existing Probabilistic Safety Assessment (PSA) study remains valid as a representative model of the plant;
    - Whether the results of the PSA show that the risks are sufficiently low and well balanced for all postulated initiating events and operational states;
    - Whether the scope (which should include all operational states and identified internal and external hazards), methodologies and extent (i.e., Level 1, 2 or 3) of the PSA are in accordance with current national and international standards and good practices;
    - Whether the existing scope and application of PSA are sufficient.
- The objective of the review of Safety Factor 7 is to determine the adequacy of protection of the plant against internal and external hazards, with account taken of the plant design, site characteristics, the actual condition of the SSCs important to safety and their predicted state at the end of the period covered by PSR2, and current analytical methods, safety standards and knowledge.

2.0 REVIEW SCOPE AND METHODOLOGY

PSR2 is focused on the extension of Pickering NGS operations beyond 2020. Thus, it is important that the methodology for PSR2 be focused on addressing aspects of the review that are likely to have material impact in terms of identifying enhancements that will be reasonable and practicable to implement during the remaining commercial life of the plant. PSR2 conducts reviews against a baseline of the PSR1 work. It is important to note that OPG conducts regular reviews of new and revised Codes and Standards, so a large amount of information is already available to assist in the Safety Factor reviews. In OPG letter N-CORR-00531-05661, W.M. Elliott to P.A Webster and M. Santini, "Design Codes and Standards Effective Dates for OPG Nuclear Fleet" [9], OPG stated:

> *OPG commits to completing a code-over-code review (i.e., review of changes) of subsequent editions, addendum and/or updates of the Codes and Standards listed in Attachment 1* [of the referenced document]*. Key emerging issues due to major changes in the codes will be addressed immediately, or as agreed with the CNSC on a case-by-case basis. Otherwise, OPG will confirm in a letter to the CNSC that these reviews have been completed and there are no significant technical issues...*

As a result, many of the updated codes and standards issued since PSR1 have already had gap assessments performed, to varying degrees of detail, which are utilized and cited in the present Pickering PSR2.

As a subsequent PSR, PSR2 focuses on changes in requirements, plant conditions, operating experience and new information. Since PSR2 is an update of previous ISRs, it incorporates reviews of L/R/C/Ss that have occurred as new versions have been issued. Therefore, clause-by-clause reviews of the majority of applicable L/R/C/Ss have already been completed and there is little value in repeating that process. If clause-by-clause reviews were to be undertaken in PSR2, a major portion of the review effort would be consumed by repackaging existing information that remains largely applicable and, therefore, is not contributing to the identification of new insights and enhancements. A more constructive approach is therefore applied that maximizes the value and usefulness of the work by focusing attention where it is most beneficial, i.e., on identifying new issues. The primary objective for this work, which is to identify safety significant enhancements that may be implemented during the limited remaining life of the station, is achieved using this process and is expected to result in the same (safety significant) Global Issues being identified as would result from a clause-by-clause assessment.

Since this assessment is a subsequent PSR, the focus is on identifying differences between what was previously assessed and what is now different within the current Pickering PSR2 Assessment Basis. In general, these differences relate to:

- More recent (new or revised) L/R/C/S versions than what was previously assessed;[3]

- Safety significant differences between Pickering and Darlington, if the Darlington ISR is the basis for the earlier assessment;

- Implications of extending Pickering NGS operation beyond 2020; and

- Safety significant differences between Pickering Units 1,4 and Units 5-8.

In most cases L/R/C/S reviews are incremental in nature and performed by topic or subject matter for revised requirements. The rationale for this is that new or updated requirements that need to be included in PSR2 are predominantly replacements for other L/R/C/S that were previously assessed, and specify requirements that can be readily mapped to existing OPG programs.

To align with the goals of a subsequent PSR, the following three tiers of reviews are applied for PSR2:

- Clause-by-Clause review: New L/R/C/S referenced in Pickering PROL 48.02/2018 (listed in Appendix C of the Licence Conditions Handbook) will be subjected to a clause-by-clause type review. In a clause-by-clause review, conformance with individual clauses is demonstrated by supporting evidence stating whether the requirements stipulated in the requirement document are met;

- High Level review: New L/R/C/S not referenced in Pickering PROL 48.02/2018 but which are in the PSR2 Assessment Basis will be subject to a high level review. In a high level review, the degree of conformance with clauses or groups of clauses in the L/R/C/S is demonstrated by supporting evidence stating whether the intent of the requirements stipulated in the requirement document are met; and

- Incremental review: For L/R/C/Ss that have been reviewed in PSR1 but have had revisions since the last review, a topical review will be performed of the changes. (Note: Incremental reviews may also include high level review elements if required, e.g., where potentially safety significant L/R/C/S clauses were not addressed in PSR1 (due to significant structural or technical changes to an L/R/C/S since previous PSR1 reviews), or where past Pickering NGS L/R/C/S reviews do not exist and application of Darlington ISR conclusions is

---

[3] "New" refers to a code or standard that was not previously considered in the context of earlier assessments. "Revised" refers to an updated version of a code or standard that was previously considered in the context of earlier assessments. Where a document has a new number/type, but addresses the same topic from the same organization, it is a "revised", not "new", document (e.g., if a REGDOC replaces a CNSC G or RD document).

not fully sufficient (based on the need for station-specific supporting evidence).)

Most of the L/R/C/Ss in the PSR2 Assessment Basis receive incremental reviews since PSR2 is an update of previous PSR1 assessments and clause-by-clause or high level reviews for the majority of the L/R/C/Ss in the PSR2 Assessment Basis have already been completed. Implementation plans (including gap analyses or code-over-code reviews) also exist for the latest editions of many L/R/C/Ss. As a result, an incremental review is also used in circumstances where a L/R/C/S in the PSR2 Assessment Basis was not assessed in previous PSR1 reviews but an implementation plan currently exists for compliance.

The PSR2 incremental reviews in this report include an assessment of the intent of recent changes to the L/R/C/Ss identified in Table 1 on a topic or subject-matter basis where there is potential to impact nuclear safety. Incremental reviews provide:

- A summary of the purpose of the L/R/C/S;
- Pertinent background information about the current revision of the L/R/C/S that is being considered;
- Identification of which Safety Factor(s) are applicable to the current revision of the L/R/C/S;
- A description of which version(s) of the L/R/C/S were assessed for PSR1 (i.e., Darlington ISR (where applicable), Pickering B ISR and PARTS code reviews);
- Identification of whether the current version of the L/R/C/S is an update of a previous version of the L/R/C/S that was assessed in PSR1 (and if so, a description of the major changes in the latest revision is provided as discussed below);
- An assessment of the applicability of PSR1 assessment findings (gaps and conclusions), including the implications of extending Pickering NGS operation beyond 2020 if any;
- An assessment of the applicability of assessment findings that address more recent (post-PSR1) editions of the L/R/C/S, including any implementation or transition plans that are already committed to by OPG; and
- Where PSR1 and post-PSR1 assessments are not sufficient to address changes in the latest edition of the L/R/C/S, an assessment of the changes from the previously assessed edition of the L/R/C/S (including identification of any safety significant PSR2 gaps which result).

High Level reviews provide the same information as above, where applicable, in a similar format. However, given that High Level L/R/C/Ss generally have not received past assessment during PSR1, the Incremental review content is augmented by a high level, section-by-section assessment of the degree of conformance of Pickering NGS with the L/R/C/S (demonstrating, with supporting evidence, whether the intent of the requirements stipulated in the document are met).

There are currently no L/R/C/S clause-by-clause reviews identified in the PSR2 Assessment Basis.

The Safety Factor 1, 5, 6, and 7 L/R/C/S reviews identify Compliances and Gaps as defined below:

- Compliance:
    - Where an Incremental review has been performed, Compliance indicates that the change in the safety requirement, per the topical review, is met.
    - Where a High Level review has been performed, Compliance indicates that the intent of the safety requirement is met.
- Gap:
    - Where an Incremental review has been performed, a Gap indicates that the change in the safety requirement, per the topical review, is not met.
    - Where a High Level review has been performed, a Gap indicates that the intent of the safety requirement is not met.

The reviews assume that use of the word:

- "Shall" is used in an L/R/C/S to express a requirement, i.e., a provision that the licensee is obliged to satisfy in order to comply with the standard;
- "Should" is used to express a recommendation or that which is advised but not required;
- "May" is used to express an option or that which is permissible within the limits of the standard; and
- "Can" is used to express possibility or capability.

Table 1 identifies the L/R/C/Ss in the PSR2 Assessment Basis that are applicable to Safety Factors 1, 5, 6, and 7, with several exceptions discussed below. Table 1 also identifies the modern version and date of each L/R/C/S to be considered, the Safety Factor(s) to which each document is applicable, and the type of review that was completed in PSR2. Reviews for each L/R/C/S are provided in Appendix B, and results are summarized in Section 3.0.

The following L/R/C/Ss applicable to Safety Factors 1, 5, 6 and 7 are excluded from Table 1 below. Specifically:

- CSA N286-12, "Management System Requirements for Nuclear Facilities", which is applicable to Safety Factors 5 and 6;
- CSA N286.7-16, "Quality Assurance of Analytical, Scientific and Design Computer Programs", which is applicable to Safety Factors 1, 5, 6, and 7;
- CSA N285.4-14, "Periodic Inspection of CANDU Nuclear Power Plant Components", which is applicable to Safety Factor 1;
- CSA N285.5-13, "Periodic Inspection of CANDU Nuclear Power Plant Containment Components", which is applicable to Safety Factor 1;
- CSA N287.2-08, "Material Requirements for Concrete Containment Structures for CANDU Nuclear Power Plants", which is applicable to Safety Factor 1;
- CSA N289.1-08, "General Requirements for Seismic Design and Qualification of CANDU Nuclear Power Plants", which is applicable to Safety Factor 1;
- CSA N289.2-10, "Ground Motion Determination for Seismic Qualification of Nuclear Power Plants", which is applicable to Safety Factor 1;
- CSA N289.3-10, "Design Procedures for Seismic Qualification of Nuclear Power Plants", which is applicable to Safety Factor 1;
- CSA N289.4-12, "Seismic Instrumentation Requirements for Nuclear Power Plants and Nuclear Facilities", which is applicable to Safety Factor 1;
- CSA N289.5-12, "General Requirements for Seismic Design and Qualification of CANDU Nuclear Power Plants", which is applicable to Safety Factor 1;
- CNSC G-278 (2003), "Human Factors Verification and Validation Plans", which is applicable to Safety Factor 1;
- CNSC G-276 (2003), "Human Factors Engineering Program Plans", which is applicable to Safety Factor 1;
- CNSC REGDOC-2.3.2 (2015), "Accident Management, Version 2", which is applicable to Safety Factors 1, 5, 6, and 7;
- CSA N286.7.1-09, "Guideline for the Application of N286.7-99, Quality Assurance of Analytical, Scientific, and Design Computer Programs for Nuclear Power Plants", which is applicable to Safety Factors 1, 5, 6 and 7; and

- CSA N290.12-14, "Human Factors in Design for Nuclear Power Plants", which is applicable to Safety Factor 1.

The reviews for the above L/R/C/Ss are provided in References [4], [5] and [6] and findings are not duplicated in this report.

Table 1: Applicable L/R/C/Ss for Pickering PSR2 Safety Factors 1, 5, 6, and 7

#	Document Number	Document Title	Modern Version for PSR2	Applicable Safety Factors	Type of Review	Review Type Basis
L/R/C/Ss Referenced in Pickering NGS PROL 48.02/2018						
1	CSA N285.0	General Requirements For Pressure-Retaining Systems and Components in CANDU Nuclear Power Plants	N285.0-12	1	Incremental	N285.0 addressed as part of Pickering B and Darlington ISRs and PARTS.
2	CSA N293	Fire Protection for Nuclear Power Plants	N293-12	1, 7, 13	Incremental	N293 addressed as part of Pickering B and Darlington ISRs and PARTS.
3	CNSC REGDOC-2.4.1	Deterministic Safety Analysis	2014	5, 7	Incremental	C-6 addressed as part of the Pickering B ISR and PARTS. S-310 and RD-310 addressed as part of the Pickering B and Darlington ISRs, respectively. Implementation plan in place and gap assessment between REGDOC-2.4.1 and OPG Safety Analysis Program already performed.
4	CNSC REGDOC-2.4.2	Probabilistic Safety Assessment (PSA) for Nuclear Power Plants	2014	6, 7	Incremental	S-294 addressed as part of Pickering B and Darlington ISRs. Implementation plan in place.
Additional L/R/C/Ss						
5	CSA N287.1	General Requirements for Concrete Containment Structures for Nuclear Power Plants	N287.1-14	1	Incremental	N287.1 addressed as part of Pickering B and Darlington ISRs and PARTS.

[4] As discussed in Appendix B.29, a gap analysis for N290.7-14 has been completed by OPG and satisfies the intent of this PSR2 High Level Review. For reasons of security and confidentiality, the findings of this gap analysis will not be discussed in PSR2.

3.0 RESULTS AND CONCLUSIONS

The results of the PSR2 reviews of the L/R/C/Ss listed in Table 1 are summarized in Table 2 below. Additional background information and details regarding the gaps listed in Table 2 are provided in Appendix B of this report.

Table 2: PSR2 L/R/C/S Review Results for Safety Factors 1, 5, 6, and 7

Appendix Section #	L/R/C/S Reviewed	L/R/C/S Review Results
B.1	CSA N285.0-12, "General Requirements For Pressure-Retaining Systems and Components in CANDU Nuclear Power Plants"	There are two PSR2 CSA N285.0-12 (including Updates No. 1 and No. 2) gaps which relate to Safety Factor 1 (Plant Design): 1. Clause A.2.3.1 of CSA N285.0-06 identifies that for Shutdown Systems, pressure-retaining portions shall be classified as Class 1, except for three listed exceptions. It was identified during the Pickering B ISR that a limited number of Liquid Injection Shutdown System (LISS) components, which should have been Class 1, were purchased and installed as Class 3. In follow-up, OPG proposed four actions to address the deficiency. When refurbishment was not pursued, a code classification concession was accepted for continued operations. This code classification concession and the four actions identified in the Pickering B ISR gap resolution need to be reconsidered in the context of operation of Pickering NGS beyond 2020. Therefore, this has been identified as a PSR2 gap. 2. The PARTS review against CSA-N285.0-95 identified two Acceptable Deviations relating to Clause 7.0 requiring confirmation that the allowable cycles for fatigue would not be exceeded. For Pickering Units 1,4 and Units 5-8 operation beyond 2020, further confirmation is required that the allowable cycles for fatigue will continue to bound current service limits for extended operation. Therefore, this has been identified as a PSR2 gap.
B.2	CSA N293-12, "Fire Protection for Nuclear Power Plants"	There are three PSR2 gaps for CSA N293-12 which relate to Safety Factor 1 (Plant Design): 1. Clause 7.2.1.10.1 of CSA N293-12 states: "A display and control centre shall be located in the MCR [Main Control Room]… capable of providing detailed information on the location and nature of the signal. In addition, the panel operator shall be able to control the fire alarm system without having to leave his or her station." Pickering 014 Display Annunciation Station 014-67140-WS2342 in the Emergency Operating Centre is capable of providing annunciation only, and there is no Display Annunciation Station in the Pickering 014 MCR (although there is limited annunciation). Therefore, this has been identified as a PSR2 gap.

Appendix Section #	L/R/C/S Reviewed	L/R/C/S Review Results
		2. Clause 7.2.1.13 of CSA N293-12 states: "Electrical conductors that are installed in service spaces containing other combustible materials and that are used in connection with fire alarm systems and emergency equipment, including fire alarm cables… shall be capable of performing their intended functions for not less than 1 hour after the start of a fire." Modifications to the Fire Protection System meet the requirements of CAN/ULC-S524 which mandates a 1 hour fire rating as described in Section 2.5 of NA44-DM-71400.2-00001 R001, Section A.2 of NA44-DM-71400-00002 R000 and Section 2 of NK30-DM-71400-00001 R006. This is achieved by the use of Edwards System Technology (EST) that connects the fire alarm control panels via a data communication link with dual redundant circuit wiring paths. However, existing Pyrotronics fire alarm control panels are not similarly connected and, hence, may be susceptible to loss of alarm signal due to spot burning of a cable. While measures such as lack of combustible material in service spaces, combustible transient material control practices, and inherent protection afforded by Pickering NGS cable routing practices used in the Fire Protection systems mitigate the lack of such a feature, it could not be confirmed based on existing documentation that all essential fire alarm cables are capable of performing their intended functions for not less than 1 hour after the start of a fire to meet the requirement of N293-12 sub-clause 7.2.1.13. As a result, this has been identified as a PSR2 gap. 3. Clause 7.3.2.2 (d) of CSA N293-12 states: "At a minimum, the fire protection water pumping system shall consist of at least one diesel-engine-driven fire pump and one electric-motor-driven fire pump set, with each pump set being capable of providing, the flow rate and pressure specified in Item (a)". This Clause is met at Pickering Units 1,4 with the provision of diesel-driven firewater pumps, backed up by supplies from the High Pressure Service Water (HPSW) system (as noted in the Pickering A Safety Report NA44-SR-01320-00001 R015, Section 11.5.1.1). It is not met at Pickering Units 5-8, where the Fire Protection System is comprised of the HPSW supplies from the four units only. As a result, Pickering Units 5-8 does not comply with Clause 7.3.2.2 (d) of CSA N293-12 and this has been identified as a PSR2 gap.

Appendix Section #	L/R/C/S Reviewed	L/R/C/S Review Results
B.3	CNSC REGDOC-2.4.1 (2014), "Deterministic Safety Analysis"	There are two PSR2 CNSC REGDOC-2.4.1 (2014) gaps which relate to Safety Factor 5 (Deterministic Safety Analysis): 1. The REGDOC-2.4.1 Implementation Plan and associated gap assessments capture all gaps related to REGDOC-2.4.1 and incorporate a systematic selection of the scope of work to address the most pertinent gaps in accordance with the graded approach to upgrading existing analyses. REGDOC-2.4.1 compliant analysis activities and progress related to REGDOC-2.4.1 implementation in the Pickering Licence Conditions Handbook are tracked according to the CNSC Compliance Verification Criteria. Since the implementation is in progress, this has been identified as a PSR2 gap for Pickering NGS REGDOC-2.4.1 compliance. 2. As described in the REGDOC-2.4.1 Implementation Plan: "Limited upgrades are proposed in the Pickering A and B Plan, which has been developed with consideration for demonstration of continued safe operation while accounting for the limited remaining operating life of the Pickering Units". The REGDOC-2.4.1 Implementation Plan for Pickering did not consider operation past 2020 and therefore the need for review and update of the Implementation Plan in the context of operation of Pickering NGS beyond 2020 is identified as a PSR2 gap. This will be informed by the timeline of the Darlington REGDOC-2.4.1 Implementation Plan, and the limited additional years of Pickering NGS operation.
B.4	CNSC REGDOC-2.4.2 (2014), "Probabilistic Safety Assessment (PSA) for Nuclear Power Plants"	There is one PSR2 CNSC REGDOC-2.4.2 (2014) gap which relates to Safety Factor 6 (Probabilistic Safety Assessment): 1. The REGDOC-2.4.2 Pickering Implementation Plan agreed to with the CNSC did not consider operation beyond 2020 and therefore, the review and update of the Implementation Plan in the context of operation of Pickering NGS beyond 2020 is required. Therefore, this has been identified as a PSR2 gap.
B.5	CSA N287.1-14, "General Requirements for Concrete Containment Structures for Nuclear Power Plants"	There are no PSR2 gaps for CSA N287.1-14. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with CSA N287.1-14.
B.6	CSA N287.3-14, "Design Requirements for Concrete Containment Structures for Nuclear Power Plants"	There are no PSR2 gaps for CSA N287.3-14. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with CSA N287.3-14.

Appendix Section #	L/R/C/S Reviewed	L/R/C/S Review Results
B.7	CSA N287.5-11, "Examination and Testing Requirements for Concrete Containment Structures for Nuclear Power Plants"	There is one PSR2 CSA N287.5-11 gap which relates to Safety Factor 1 (Plant Design): 1. The Concrete Containment Structures (CCSs) at Pickering A and B were built and tested to meet the 1965 and 1970 National Building Code of Canada requirements, respectively, prior to the initial issuance of CSA N287.5. No assessments exist which demonstrate that the requirements in effect during construction of Pickering NGS CCSs comply with the requirements of CSA N287.5. Ongoing confirmation that the Pickering NGS CCSs remain fit for service is demonstrated via periodic and in-service inspections conducted in accordance with the requirements of CSA N285.5 and N287.7, and the resultant inspection reports attest to the quality of the design. In addition, the Engineering Change Control (ECC) process ensures that any design changes made to the Pickering CCSs will comply with N287.5 going forward, as applicable. The original Pickering construction included requirements for tests and quality control procedures which generally meet the intent of N287.5. Furthermore, retroactive application of N287.5 to the as-built design of CCSs cannot be practically achieved without rebuilding them. Nevertheless, there is a PSR2 gap for Pickering NGS given that compliance with the specific requirements of N287.5 has not been demonstrated.
B.8	CSA N290.0-11, "General requirements for Safety Systems of Nuclear Power Plants"	There are three PSR2 N290.0-11 gaps which relate to Safety Factor 1 (Plant Design): 1. The Darlington ISR identified a gap against Clause 4.14.10 of N290.0-11 as a result of the lack of design standards related to Human Factors Engineering (HFE) or HFE activities being formally documented when the control rooms were originally designed and constructed. Pickering NGS has many years of successful Special Safety System (SSS) operation and the absence of formal HFE in the original design is not expected to have any nuclear safety significance relating to SSSs. However, the Darlington gap is also applicable to Pickering NGS and is therefore identified as a PSR2 gap. 2. Clause 4.2 of N290.0-11 requires that Plant States be grouped into several categories, including Anticipated Operational Occurrences (AOOs). This is consistent with clauses of REGDOC-2.4.1 and REGDOC-2.5.2 related to identification and classification of initiating events. Since AOOs have not been identified and analyzed in the current Pickering Safety Reports, the requirements and credits attributed to the Special Safety Systems for AOOs, if any, cannot be readily ascertained. This

Appendix Section #	L/R/C/S Reviewed	L/R/C/S Review Results
		issue has therefore been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation. 3. OPG is currently in the process of completing the High Energy Line Break Assessment (HELBA) for Pickering NGS. Preliminary results show that there would be no consequential damage caused by the rupture of high energy pipes inside containment to safety related equipment, beyond that already accounted for in the Safety Reports. The final HELBA reports for Pickering Units 5-8 have been completed, while Pickering Units 1,4 are expected to be completed in 2017. Since this work has not been completed for Pickering 1,4, this is identified as a PSR2 gap.
B.9	CSA N290.1-13, "Requirements for the Shutdown Systems of Nuclear Power Plants"	There is one PSR2 CSA N290.1-13 gap which relates to Safety Factor 1 (Plant Design): 1. Clause 4.1.8.2 of CSA N290.1-13 is for a new plant and requires remote tripping and monitoring capability for both Shutdown Systems. Pickering Units 1,4 only have one Shutdown System with tripping capability from separate logic (SDSA and SDSE). Remote tripping capability is available for Pickering 5-8 SDS2 and Pickering 1,4 SDSE. However, Pickering Units 5-8 and 1,4 do not have remote tripping and monitoring capability for SDS1 or SDSA respectively. Therefore, this has been identified as a PSR2 gap.
B.10	CSA N290.2-11, "General Requirements for Emergency Core Cooling systems of Nuclear Power Plants"	There are two PSR2 CSA N290.2-11 gaps which relate to Safety Factor 1 (Plant Design): 1. Clause 5.2.1.2 of CSA N290.2-11 requires that Emergency Coolant Injection System (ECIS) design requirements be based on the assumption that the least effective of the Shutdown Systems has operated successfully. The Pickering Units 5-8 Safety Report analysis does address this requirement and the requirement is also contained in the Pickering Units 5-8 Design Requirements. However, this requirement cannot be met for Pickering Units 1,4 since there is only one Shutdown System (albeit with tripping capability from separate SDSA and SDSE logic). Therefore, this has been identified as a PSR2 gap. 2. Clause 5.14.11 of CSA N290.2-11 requires instrumentation to be available to monitor post-accident effectiveness and to determine the extent of plugging of ECIS debris interceptors (strainers). While relative health of a strainer can be inferred by a combination of ECIS recovery pump performance and reactor building water level, there is no direct correlation between these conditions and debris loading available.

Appendix Section #	L/R/C/S Reviewed	L/R/C/S Review Results
		Therefore, this has been identified as a PSR2 gap (which is applicable to both Pickering Units 5-8 and 1,4).
B.11	CSA N290.3-11, "Requirements for the Containment System of Nuclear Power Plants"	There is one PSR2 CSA N290.3-11 gap which relates to Safety Factor 1 (Plant Design): 1. Per CSA N290.3-11, a Containment Energy Management System (EMS) and Radionuclide Management System (RMS) are required to protect containment and minimize radiological releases for Beyond Design Basis Accidents (BDBAs). The Pickering EMS and RMS use the Filtered Air Discharge System (FADS) and Reactor Building Air Cooling Units (ACUs). Enhancements to the AC power supplies to these systems and related loads are being provided by Phase 2 Emergency Mitigating Equipment (EME), which is not yet fully implemented. This PSR2 gap has been identified to track the implementation of Phase 2 EME such that it can be used to support the EMS and RMS.
B.12	CSA N290.4-11, "Requirements for Reactor Control Systems of Nuclear Power Plants"	There is one PSR2 CSA N290.4-11 gap which relates to Safety Factor 1 (Plant Design): 1. Clause 4.2 and Clause 5.19 of CSA N290.4-11 require the capability of the Reactor Regulating System (RRS) to be assessed to deal with AOOs, by preventing them from escalating into Design Basis Accidents (DBAs) that would require Shutdown System action. In general, the setback function (and stepback in Pickering Units 5-8) addresses this requirement; however, AOOs have not been identified and analyzed in the current Pickering Safety Reports. Therefore, this has been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation. Note: There are also additional clauses which refer to requirements of RRS during AOOs (Clauses 5.6.2, 5.19, 5.16.1); however, for convenience, all issues related to AOO requirements for RRS in N290.4-11 are captured under this one PSR2 gap.
B.13	CSA N290.5-06 (R2011) including Update No. 1, "Requirements for Electrical Power and Instrument Air Systems of CANDU Nuclear Power Plants"	There is one PSR2 CSA N290.5-06 (R2011) including Update No. 1 gap which relates to Safety Factor 1 (Plant Design): 1. A gap exists for the Pickering Units 1,4 and 5-8 Instrument Air and Electrical Systems on Clauses 7.1 and 7.4.2 of N290.5-06 (R2011) including Update No. 1 dealing with requirements for AOOs. These clauses introduce the requirement for components to be qualified to perform their required functions during normal operation and AOOs. Only the portion of this clause on AOOs is pertinent to nuclear safety. It is likely that AOOs, due to their nature, do not result in a challenge to the qualification of systems, including Instrument Air and Electrical

Appendix Section #	L/R/C/S Reviewed	L/R/C/S Review Results
		systems. However, AOOs have not been identified and analyzed in the current Pickering Safety Reports. This issue has therefore been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation.
B.14	CSA N290.6-09, "Requirements for Monitoring and Display of Nuclear Power Plant Safety Functions in the Event of an Accident"	There are no PSR2 gaps for CSA N290.6-09. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with CSA N290.6-09.
B.15	CSA N290.11-13, "Requirements for Reactor Heat Removal Capability During Outage of Nuclear Power Plants"	There are three PSR2 CSA N290.11-13 gaps which relate to Safety Factor 1 (Plant Design): 1. The CSA N290.11-13 Clause 5.1.1 to 5.1.5 requirement for back-up heat sinks to mitigate the conditions following an AOO is not specified in governance/procedures. Loss of a division of power, a single component failure, etc., which are likely to be in the set of AOOs, are accounted for in the specification of heat sinks. However, AOOs have not been identified and analyzed in the current Pickering Safety Reports. This issue is therefore a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation. 2. Clause 5.6.1 of CSA N290.11-13 requires design reliability to be established for outage heat sinks. Although some emergency heat sinks (e.g., Emergency Boiler Water Supply and Emergency Water Supply) have design reliability requirements, design reliability requirements have not been established for all normal and back-up heat sinks used at Pickering. Reliability of all outage heat sinks (including those without explicit targets) is managed under the Risk & Reliability Program (both through unavailability models as well as through Probabilistic Safety Assessment), hence reactor safety impact is assessed and monitored. However, there is a PSR2 gap with respect to establishment of design reliability requirements for Pickering Units 1,4 and 5-8 outage heat sinks. 3. Clause 5.6.1 of CSA N290.11-13 requires that the designed reliability for process heat sinks be consistent with AOO frequency limits, such that an emergency heat sink does not need to be used for an AOO. AOOs have not been identified and analyzed in the current Pickering Safety Reports. This issue is therefore a PSR2 gap and is being addressed as part of REGDOC-2.4.1 implementation.

Appendix Section #	L/R/C/S Reviewed	L/R/C/S Review Results
B.16	CSA N290.14-15, "Qualification of Digital Hardware and Software for Use in Instrumentation and Control Applications for Nuclear Power Plants"	There is one PSR2 CSA N290.14-15 gap relating to Safety Factor 1 (Plant Design): 1. Correspondence with the CNSC identifies all of the software application qualifications for software Categories 1, 2 and 3 from January 1, 2007 to the time of the correspondence (June 2016). However, an evaluation of legacy Real-Time Process Computing applications with respect to the requirements of N290.14-15 for Categories 1, 2 and 3 software has not been performed. Therefore, this has been identified as a PSR2 gap.
B.17	CSA N291-15, "Requirements for Safety-related Structures for Nuclear Power Plants"	There are three PSR2 CSA N291-15 gaps which relate to Safety Factor 1 (Plant Design): 1. Clause 6.5.2.2 of CSA N291-15 imposes new requirements for bolted connections in members that are part of the seismic load resisting system. Pickering NGS structures were not explicitly designed to meet these requirements and this is therefore identified as a PSR2 gap. 2. Clause 9 of CSA N291-15 contains new requirements related to aging management (including design provisions to account for aging) that are not in CSA N291-08 and that may have significance for operation of Pickering beyond 2020. Pickering structures were not explicitly designed to meet these requirements and this is therefore identified as a PSR2 gap. 3. Clauses 6.1.1(b) and 6.9.2.1.4 of CSA N291-15 state requirements for aspects of the design that are specifically based on the plant service life. Pickering structures were not explicitly designed or assessed in relation to the requirements of these clauses for operation beyond 2020. This is identified as a PSR2 gap. There is also one PSR2 gap for CSA N291 related to submission of Periodic Inspection Plans and Life Cycle Management Plans for a number of safety-significant civil structures to address fitness for service "to end of mission time" (which will need to be extended for Pickering operation beyond 2020). The gap is related to Safety Factor 4 (Aging). This issue is identified as a PSR2 gap in OPG Report P-REP-03680-00024 R000, "Pickering 5-8 Continued Operations Plan Review in Support of PNGS Periodic Safety Review 2 (PSR2)". Therefore, a duplicate gap has not been created under CSA N291-15.
B.18	CSA N285.6 Series-12, "Material Standards for Reactor Components for CANDU Nuclear Power Plants"	There are no PSR2 gaps for CSA N285.6 Series-12. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with CSA N285.6 Series-12.

Appendix Section #	L/R/C/S Reviewed	L/R/C/S Review Results
B.19	ASME B31.1-14, "Power Piping"	There are no PSR2 gaps for ASME B31.1-14. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with ASME B31.1-14.
B.20	ASME BPVC (2015), "Boiler and Pressure Vessel Code"	There are no PSR2 gaps for ASME BPVC (2015). Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with ASME BPVC (2015).
B.21	CSA B51-14 (including Update No. 1), "Boiler, Pressure Vessel, and Pressure Piping Code"	There are no PSR2 gaps for CSA B51-14 (including Update No. 1). Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with CSA B51-14 (including Update No. 1).
B.22	NFPA 20 (2016), "Standard for the Installation of Stationary Pumps for Fire Protection"	There are no PSR2 gaps for NFPA 20 (2016). Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with NFPA 20 (2016).
B.23	NFPA 24 (2016), "Standard for the Installation of Private Fire Service Mains and Their Appurtenances"	There are two PSR2 gaps for NFPA 24 (2016) which relate to Safety Factor 1 (Plant Design): 1. For OPG Report NK30-REP-71400-10001 R001, "Fire Protection Code Compliance Review Pickering Nuclear Generating Station B", there is an outstanding issue (Deviation # 13301) which relates to NFPA 24 1970 Section 3601: "Yard post indicator valves at PNGS B are not secured in the open position as required by code" (and which applies to Pickering Units 1,4 as well as Units 5-8). Work to resolve this deviation is currently in progress with locks installed on the majority of the affected valves. Based on OPG List P-LIST-71400-00001 R000, there are a number of SSCs in the yard which directly support plant operation and which are defined as being "related to nuclear safety". As a result, fire water supply to these SSCs is a credited safety function. Deviation # 13301 is not yet complete. Therefore, this has been identified as a PSR2 gap. 2. For Pickering Units 5-8 the baseline for NFPA 24 compliance is the 1970 version of the standard. Pickering Units 1,4 have not been previously assessed against NFPA 24. Although recent changes to the 2013 and 2016 versions of NFPA 24 will be addressed in any firewater system design changes going forward (as a result of Code-over-Code reviews performed for NFPA 24), compliance has not been formally documented for Pickering Units 1,4 or Units 5-8 against the most recent versions of NFPA 24. Furthermore, there have been a large number of significant changes to NFPA 24 since 1970, including the 2002 edition which "represented a complete revision of NFPA 24". Since Pickering NGS has not demonstrated compliance with the 2016 version of NFPA 24, this has been

Appendix Section #	L/R/C/S Reviewed	L/R/C/S Review Results
		identified as a PSR2 gap. It is noted that OPG is proactively replacing portions of the firewater piping in accordance with NFPA 24, under the Pickering A Firewater Pipe Replacement Project 13-80069.
B.24	CNSC REGDOC-2.5.2 (2014), "Design of Reactor Facilities: Nuclear Power Plants"	There are ten PSR2 gaps for CNSC REGDOC-2.5.2 (2014). The gaps and their associated Safety Factor are identified below: 1. Safety Factor 5 (Deterministic Safety Analysis) – Clauses 4.2.1, 6.4 and 7.3 of REGDOC-2.5.2 introduce new requirements and limits for AOOs, DBAs and BDBAs and include specific dose limits for AOOs and DBAs. Current Pickering Safety Report analyses do not identify and classify events into these categories. Dose limits currently used in Pickering are aligned with the single failure / dual failure limits in accordance with the Pickering Licence Conditions Handbook. This issue has therefore been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation. 2. Safety Factor 6 (Probabilistic Safety Assessment) – Clause 4.2.2 of REGDOC-2.5.2 introduces new requirements and limits for probabilistic analysis risk limits, such as a core damage frequency limit of $<10^{-5}$ yrs/yr. It has not been demonstrated that these requirements can be achieved. Therefore, this has been identified as a PSR2 gap. 3. Safety Factor 1 (Plant Design) – Containment Leak Tightness for Design Extension Conditions (DECs): Clauses 7.3 and 8.6.12 of REGDOC-2.5.2 require containment to provide a leak tight barrier following DECs with severe core damage for a period sufficient to implement off-site emergency measures. REGDOC-2.5.2 guidance suggests this period be at least 24 hours. Such a requirement does not exist in BDBA/Severe Accident (SA) mitigation, so this represents a PSR2 gap. 4. Safety Factor 1 (Plant Design) – On-Demand Reliability of Safety Systems: Clause 7.6 of REGDOC-2.5.2 requires all SSCs important to safety (SIS) to meet an on-demand failure rate of $<10^{-3}$ yrs/yr. This requirement is not met for several systems including Pickering 1,4 ECI and is therefore identified as a PSR2 gap. 5. Safety Factor 1 (Plant Design) – Sharing of Safety Systems and Turbine Hall: Clause 7.6.5 of REGDOC-2.5.2 has a new requirement that sharing of safety systems and the turbine generator building not be permitted. Pickering Units share Emergency Coolant Injection (ECI) and Negative Pressure

Appendix Section #	L/R/C/S Reviewed	L/R/C/S Review Results
		Containment (NPC), as well as the turbine hall; therefore, this has been identified as a PSR2 gap. 6. Safety Factor 1 (Plant Design) – Allowable Times for Crediting On-Site Operator Actions: Clauses 7.10 and 8.10.4 of REGDOC-2.5.2 establish new time limits for crediting operator actions, i.e., 30 minutes for MCR actions and 1 hour for field actions. Pickering NGS has not demonstrated that deterministic safety analysis consequences are acceptable if MCR and field action are not credited for these times respectively. Therefore, this has been identified as a PSR2 gap. 7. Safety Factor 1 (Plant Design) – Seismic Qualification and Design: Clause 7.13.1 of REGDOC-2.5.2 requires that Beyond Design Basis (BDB) Earthquake seismic margin be a factor of 1.67 beyond that required for the new plant Design Basis Earthquake (DBE). Fragility evaluations were completed for seismic mitigating SSCs, however, based on available information it could not be confirmed that the new plant BDB Earthquake margin of 1.67 would be achieved. Therefore, this has been identified as a PSR2 gap. 8. Safety Factor 1 (Plant Design) – Human Factors in Design: Clauses 7.21 and 8.10.1 of REGDOC-2.5.2 introduce new requirements for the systematic application of HFE principles to plant design. Many years of safe and reliable operating experience indicate that the design and processes for integration of human interactions with the plant were and remain robust. However, Pickering plant design predates the current requirements for incorporating HFE into the design and the existing plant has not been systematically demonstrated to meet the requirements for a new plant. Therefore, this has been identified as a PSR2 gap. 9. Safety Factor 1 (Plant Design) – Detection/Isolation of ECI Heat Exchanger Tube Leak: Clause 8.5 of REGDOC-2.5.2 requires ECI recovery heat exchanger tube leak detection capability. Pickering Units 5-8 ECI recovery heat exchangers do not have leak detection capability on the cooling water side. Therefore, this has been identified as a PSR2 gap. 10. Safety Factor 1 (Plant Design) – Safety Parameter Display System Qualification for DECs: Clause 8.10.1.1 of REGDOC-2.5.2 requires the MCR to contain a Safety Parameter Display System (SPDS) that presents sufficient information on safety-critical parameters for the diagnosis and mitigation of DBAs and DECs. The SPDSs are to be qualified for DEC and have parameters available in both the MCR and Secondary Control Areas (SCA), per Clause 8.10.2. Pickering SPDSs are not Review Level Condition (RLC) qualified or available in all

Appendix Section #	L/R/C/S Reviewed	L/R/C/S Review Results
		locations. As part of the Fukushima follow-up, instrumentation to support critical parameters required to function for DECs has been evaluated for survivability. The instrument loops associated with these parameters have been identified for use in Critical Safety Parameter Monitoring (CSPM) and BDBA procedures. However, the indications from these loops are not in one central location and, in some cases, require field action (e.g., power) to obtain data. This does not fully satisfy the requirements to have these parameters available from a SPDS in the MCR and SCA. Therefore, this has been identified as a PSR2 gap relating to the new plant requirement to have SPDS that is DEC qualified and with parameters available in the MCR and SCA.
B.25	CNSC G-144 (2006), “Trip Parameter Acceptance Criteria for the Safety Analysis of CANDU Nuclear Power Plants”	There are no PSR2 gaps for CNSC G-144 (2006). Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with G-144 (2006).
B.26	CNSC G-149 (2000), “Computer Programs Used in Design and Safety Analyses of Nuclear Power Plants and Research Reactors”	There are no PSR2 gaps for CNSC G-149 (2000). Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with G-149 (2000).
B.27	CNSC R-77 (1987), “Overpressure Protection Requirements for Primary Heat Transport Systems in CANDU Power Reactors Fitted with Two Shutdown Systems”	There are no PSR2 gaps for CNSC R-77 (1987). Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with CNSC R-77 (1987).
B.28	CSA N288.2-14, “Guidelines for Calculating Radiological Consequences to the Public from a Release of Airborne Radioactive Material for Nuclear Reactor Accidents”	There is one PSR2 CSA N288.2-14 gap which relates to Safety Factor 5 (Deterministic Safety Analysis): 1. Safety Report upgrades currently underway for Pickering as part of REGDOC-2.4.1 implementation for the period of 2017-2021 will utilize methods consistent with N288.2-14. The REGDOC-2.4.1 Implementation Plan update will consider the incremental implications of Pickering operation beyond 2020, including any considerations of N288.2 revisions. This issue has therefore been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation.

Appendix Section #	L/R/C/S Reviewed	L/R/C/S Review Results
B.29	CSA N290.7-14, "Cyber-Security for Nuclear Power Plants and Small Reactor Facilities"	The gap analysis, N-REP-69000-10003 R000, "Gap Analysis Between CSA N290.7-14 Cyber Security Requirements for Nuclear Power Plants and Small Reactor Facilities" and implementation plan for N290.7-14 was accepted by the CNSC. For reasons of security and confidentiality, the findings of the gap analysis for N290.7-14 will not be discussed in PSR2.
B.30	NBCC (2010), "National Building Code of Canada"	There are no PSR2 gaps for NBCC (2010). Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with NBCC (2010).
B.31	NFCC (2010), "National Fire Code of Canada"	There is one PSR2 gap for NFCC (2010), related to piping for flammable or combustible liquids at building entrances. The gap is related to Safety Factor 1 (Plant Design). This issue is identified as a PSR2 gap in OPG Report P-REP-03680-00024 R000, "Pickering 5-8 Continued Operations Plan Review in Support of PNGS Periodic Safety Review 2". Therefore, a duplicate gap under NFCC (2010) has not been created.
B.32	CSA N290.8-15, "Technical Specification Requirements for Nuclear Power Plant Components"	There is one PSR2 CSA N290.8-15 gap which relates to Safety Factor 1 (Plant Design): 1. Clause 4.7 of CSA N290.8-15 mandates that the technical specification requires the supplier to identify and describe all digital items included in their equipment. In the event that the use of digital items is identified by OPG in advance of issuing a Request for Proposal (RFP) or Request for Quotation (RFQ), existing OPG procedures are adequate for ensuring that requirements related to digital items are documented in the technical specification. However, a requirement for a supplier to self-identify whether their product contains any digital items is not reflected in OPG governing documents. This has therefore been identified as a PSR2 gap.

Appendix B: L/R/C/S Reviews for Safety Factors 1, 5, 6 and 7

B.1 CSA N285.0-12, "General Requirements for Pressure-Retaining Systems and Components in CANDU Nuclear Power Plants"

B.1.1 Background

The following, paraphrased from CSA N285.0-12 (including Updates No. 1 and No 2) [B.1-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The CSA N285 series of Standards specifies requirements applicable to nuclear power plants in Canada and references the applicable requirements of the ASME Boiler and Pressure Vessel Code (BPVC).*
>
> *CSA N285.0 provides general requirements for pressure-retaining systems, components, and supports in CANDU nuclear power plants. It specifies the technical requirements for the design, procurement, fabrication, installation, modification, repair, replacement, testing, examination, and inspection of, and other work related to, pressure-retaining systems, components, and supports over the service life of a CANDU nuclear power plant.*

All of N285.0-12 (including Updates No. 1 and No 2) is directly relevant to Safety Factor 1 (Plant Design).

Compliance with CSA N285.0-08 (including Updates No. 1 and No. 2) [B.1-2] is currently a licence requirement for Pickering NGS (per PROL 48.02/2018) as indicated in Section 6.2 and Appendix C.1 of the R04 Pickering Licence Condition Handbook (LCH) [B.1-3].

N285.0-12/N285.6 Series-12 [B.1-1] is the second edition of the CSA N285.0/N285.6 Series. It supersedes the previous edition published in 2008, and the previous editions of CSA N285.0 published in 2006, 1995, 1991 and 1971.

There are two applicable CSA N285.0 Impact Statements: (i) The CSA Impact Statement for the new edition of CSA N285.0-12 [B.1-4] and (ii) CSA Impact Statement for Publication of CSA N285.0-12 (including Updates No. 1 and No. 2) [B.1-5]. They provide a summary of significant changes from the previous editions and are discussed in Section B.1.2 below.

The results of PSR1 CSA N285.0 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.1.2. As identified in Reference [B.1-6], the Pickering PSR2 review of CSA N285.0-12 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.

- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.1.2 Compliance Assessment for Pickering PSR2

B.1.2.1 Application of PSR1 Reviews

The versions of N285.0 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

A clause-by-clause review was performed against N285.0-06 [B.1-7] as part of the Pickering B ISR. The review was documented in the Plant Design Safety Factor Report, NK30-REP-03680-00001 R000 [B.1-8]. The report found that Pickering Units 5-8 complied with N285.0-06, except for a discrepancy against Clause A.1.5.

Clause A.1.5 states:

> *Class 3: Systems and sections of systems not classified as Class 1 or 2 and that contain radioactive substances with a tritium concentration exceeding 74 GBq/kg (2 Ci/kg) shall be classified as Class 3.*

whereas CSA N285.0-95 [B.1-9] stipulated a requirement of "tritium concentration exceeding 0.4 TBq/kg (0.01 Ci/g)".

The code review [B.1-8] further states it is improbable that this change would alter the classification of Class 3 & 6 systems.

Subsequent correspondence with the CNSC, contained in NK30-REP-03680-00016 [B.1-10], resulted in this issue not being a gap since the likelihood is low that a system containing radioactive material, initially classified as Class 6, would be impacted as a result of this classification. Therefore this is not a PSR2 gap.

Subsequent to the N285.0-06 code review in [B.1-8], NK30-REP-03680-00016 [B.1-10] documented that a gap exists against Clause A.2.3.1. The issue associated with this clause was initially an Acceptable Deviation, but subsequently identified as a gap per a CNSC request. This clause identifies that for Shutdown Systems, pressure-retaining portions shall be classified as Class 1, except for three listed exceptions. Gap 1-561 identified that some Liquid Injection Shutdown System (LISS) components, which should have been Class 1, were purchased and installed as Class 3.

To resolve the gap, a screening level review of the Shutdown System 2 (SDS2) flow diagram and System Classification List was performed. There is a limited portion of LISS that is Class 3. To meet the intent of the requirement of Clause A.2.3.1(c), the following four actions were proposed [B.1-10]:

- Update Design Documentation
- Prepare a new Design Requirement(s) for the affected Class 3 portion of LISS
- Perform Stress Analysis
- Reconciliation of materials, fabrication and installation of the affected portions with the Technical Standards & Safety Authority (TSSA).

When refurbishment was not being pursued, Section B.3.8 of the Pickering B Integrated Implementation Plan, NK30-PLAN-03680-00002 [B.1-11] indicated that the LISS code classification concession that was previously accepted by the CNSC in NK30-CORR-00531-03047 [B.1-12] was considered acceptable for Continued Operations. Closure of Gap 1-561 was requested in OPG correspondence NK30-CORR-00531-06027 [B.1-13], and accepted in CNSC letter NK30-CORR-00531-06324 [B.1-14]. This code classification concession and the four actions identified in the Pickering B ISR gap resolution need to be reconsidered in the context of operation of Pickering NGS beyond 2020. Therefore, this is identified as a PSR2 gap (**PSR2 CSA N285.0-12 Gap #1**).

Reference [B.1-8] also identified the following twelve Acceptable Deviations (ADs):

- Clause 5.2.8 identifies requirements for radioactivity concentrations used for system classification purposes. The previous code version did not contain this clause. Instead it refers to the Safety Report to define process failures, which would be used for classification. It was deemed improbable that this clause would affect classification. Therefore this not a safety significant issue and is not a PSR2 gap.
- Clauses 6.1.1.3 and 6.1.4 require the designer to register items as systems, vessels, pumps, fittings, or supports. The previous version of the code excludes supports, so they were not subject to registration. The lack of registration does not impact on the ability of the system or component to perform their required function. Therefore, this is not a PSR2 gap.
- Clause 7.6.2.4 on retention of objective evidence that intervening elements are capable of withstanding the loads imposed, is a new requirement. Manufacturers are required to supply information on support qualification to ensure the support function is taken into account in the design of the supported component. This satisfies the clause and therefore this AD is of low safety significance and is not a PSR2 gap.
- Clause 7.7.2.3 identifies considerations for the qualification of the Heat Transport System for overpressure events. In the updated version of the standard, N285.0-12 [B.1-1], the equivalent Clause 7.6.2.3 (c) has been modified to provide relaxation

consistent with Regulatory Document R-77 [B.1-15], so there is no longer a gap associated with this clause.

- Clause 12.1 identifies requirements for pressure-retaining systems documentation. Records are available for most of the important permanent design records, e.g. Class 1 stress report, but not all records are available. The completed configuration management restoration project established the documentation that is required to safely operate and maintain the station. Therefore, this AD is of low safety significance and is also not a PSR2 gap.

- Clauses 12.3.9, 12.4.7.2 and A.1.6.3.3 are very minor issues and their disposition was accepted by the CNSC in Reference [B.1-16]. They are not PSR2 gaps.

- Clause 14.5.3.1 requires documentation to be produced to demonstrate that any differences between registered designs and the as-built modification have been reviewed and reconciled. The previous code version did not include this specific requirement, therefore this process was performed by the designer informally. Reference [B.1-10] stated there was a program to clear the backlog of reconciliation statements and this was committed to the CNSC and has since been closed [B.1-17]. Related ADs against Clauses 14.5.3 and 14.5.3.2, were addressed with the same disposition as for Clause 14.5.3.1. Therefore these three ADs are not PSR2 gaps.

These ADs are not impacted by Pickering operation beyond 2020.

<u>Pickering Units 1,4</u>

For Pickering A Return to Service, the active version of the Standard at the time was CSA-N285.0-95 [B.1-9]. A review of OPG pressure boundary components was performed against N285.0-95 in an OPG letter to the CNSC, NA44-CORR-00531-00464, "Pickering A – Review of Pickering A Design to CSA-N285.0-95" [B.1-18]. A section by section review of the standard was carried out. The review concluded that the design of Pickering A meets the intent of CSA N285.0-95. The following three ADs were identified:

1. Clause 7.0 on Design Rules Intent states:

   The design will be performed in accordance with system requirement:

   - *Class 1 (ASME class 1-NB-3000)*
   - *Class 2 (ASME class 2-NC-3000)*
   - *Class 3 (ASME class 3-ND-3000)*

   For over pressure protection, systems shall comply with the requirements of the applicable rules of ASME Sections NB/NC/ND-7000.

   The disposition of this AD states:

Equipment was designed to Class A which is class 1 today and fatigue was addressed. Piping level A, B, C and D service loading were not identified as required by NCA-2142 but since the original design included 7000 cycles for fatigue, it is considered that the previous design would bound the current service limits.

For Pickering NGS operation beyond 2020, confirmation is required that the allowable cycles for fatigue will continue to bound current service limits for extended operation. This is identified as **PSR2 CSA N285.0-12 Gap #2.**

2. Another AD was identified against Clause 7.0 with the following disposition:

The original design met the requirements of Class A, B, C or B31.1. The major difference between class 1, 2, 3 and B31.1 is that class 1 piping requires fatigue analysis. For class 2, 3 and B31.1 piping fatigue was accounted for by providing a limit on the number of total cycles (7000). Pickering 'A' piping design for class 2 and 3 systems is expected to be compliant. Also, class 1 piping less than or equal to 1" in size is considered to be compliant. For class 1 piping greater than 1", the Pickering 'A' design is considered to be an acceptable deviation with current code. Since B31.1 conservatively considers fatigue by incorporating 7000 cycles for piping fatigue, it is expected that fatigue analysis would be bounded by the original design. In addition, lower allowable stresses are used by the B31.1 code, provide additional margin to the original design.

For Pickering NGS operation beyond 2020, confirmation is required that the allowable cycles for fatigue for Class 1 piping greater than 1" will continue to bound current service limits for extended operation. This specific AD relating to Class 1 greater than 1" piping is being included in **PSR2 CSA N285.0-12 Gap #2** identified above.

3. An AD was identified against Clause 14.0 which specifies the requirements for supports of pressure retaining systems. The disposition of this AD states:

In general supports were not registered as an integral part of the pressure vessel. The Pickering 'A' support design is considered to be acceptable with current code requirement.

Piping support components were selected from the Piping Standards. Engineering review has concluded that there are relatively minor variations between the present and original standards.

This is not safety significant in the context of Pickering PSR2.

Darlington NGS

The Darlington ISR review of N285.0 was initially performed using version N285.0-08 (June 2008) [B.1-19], which was documented in OPG Report NK38-REP-03680-10030 R000 [B.1-20]. The report documents a review of the compliance of eleven Darlington NGS pressure-retaining systems and concludes:

The review did not identify any ISR Gaps and found that Darlington NGS was compliant with CAN/CSA-N285.0-08.

The report did not identify any Acceptable Deviations.

Subsequent to the issue of Reference [B.1-20], an addendum was prepared to document CNSC comments on the code review. This is documented in Reference [B.1-21], which identified a new gap against Clause 7.6.2.2. The gap is a result of the current Darlington NF jurisdictional boundary not meeting the requirements of ASME BPVC, Section III, Division 1, NF requirements.

This gap was specific to the Darlington design. Further, since CSA N285.0-08 (including Updates No. 1 and No. 2) [B.1-2] is a licence requirement for Pickering NGS per Appendix C.1 of the R04 Pickering Licence Conditions Handbook [B.1-3], and compliance with N285.0-08 (including Update No. 1) [B.1-22] is confirmed in the Pickering NGS PROL Renewal Application [B.1-23], Pickering NGS is in compliance with N285.0-08 (including Update No. 1) and therefore this Darlington gap is not applicable to PSR2. The R04 Pickering Licence Conditions Handbook [B.1-3] includes the transitional provisions to N285.0-08 (including Updates No. 1 and No. 2) [B.1-2], which are discussed in B.1.2.2 below.

Following the issuance of CSA N285.0-12 (including Update No. 1) [B.1-24] in September 2013, a code refresh review was conducted and documented in OPG Report NK38-REP-03680-10136 R000 [B.1-25]. This review also assessed the same eleven Darlington systems for compliance. NK38-REP-03680-10136 R000 [B.1-25] identified that:

The eleven Darlington NGS pressure-retaining systems listed in Table 2 are in compliance with the requirements of CSA-N285.0-12 (August 2012) and Update 1 (September 2013) with the exception that the current Pressure Boundary Program Manual, N-MAN-01913.11-10000 R014 and the Pressure Boundary Program, N-PROG-MP-0004 R014 do not conform to Annex N of CSA N285.0-12 and Update No. 1, as required by Section 6.1.2 of the Darlington application for license renewal. This review also identified a need to reconcile the code effective dates of the current Pressure Boundary Program Manual and the supporting governing documents to align with CSA N285.0-12 and Update 1, upon licence renewal.

The gap is against Clause 15, which states [B.1-24]:

The licensee shall have pressure boundary program documents that indicates how the requirements of this Standard are addressed by the licensee's processes and procedures for a nuclear facility. The pressure boundary program document shall be submitted to the regulatory authority. Annex N outlines a suggested format for this document.

The gap was a result of N-MAN-01913.11-10000 [B.1-26], "Pressure Boundary Program Manual" and N-PROG-MP-0004 [B.1-27], "Pressure Boundary" not conforming to Annex N of N285.0-12 (including Update No. 1). The code refresh review [B.1-25] identified this as a requirement in Section 6.1.2 of the Darlington application for license renewal. However, the current Darlington LCH [B.1-28] only requires a "Pressure Boundary Program Document roadmap in compliance with Annex N of CSA N285.0-12 and Update No. 1" to satisfy Clause 15 of N285.0-12 (including Update No. 1). This requirement was addressed with the submission of N-LIST-00531-10003, "Index to OPG Pressure Boundary Program Elements" to the CNSC in April 2015 [B.1-29]:

> *N-LIST-00531-10003…captures the elements of Annex N, "Pressure Boundary Program Document" of CSA N285.0-12 and Update No. 1, as proposed for adoption by OPG and accepted by the CNSC. The N-LIST correlates OPG's processes and procedures to the pressure boundary program elements identified in Annex N, Table N.1.*

N-LIST-00531-10003 [B.1-30] is a programmatic document and is also listed as a relevant governing document in Section 6.2 of the R04 Pickering LCH [B.1-3]. Therefore, the gap identified in the Darlington ISR against Clause 12 of N285.0-12 (including Update No. 1) has been addressed programmatically and is not a gap for PSR2.

No Acceptable Deviations were identified.

The changes made to N285.0 since these code reviews were performed are discussed in the next section.

B.1.2.2 Application of Post PSR1 Reviews

CSA N285.0-08 (including Updates No. 1 and No. 2) [B.1-2] is a licence requirement for Pickering NGS per Appendix C.1 of the R04 Pickering Licence Conditions Handbook [B.1-3], and compliance with N285.0-08 (including Update No. 1) [B.1-22] is confirmed in the Pickering PROL Renewal Application [B.1-23]. The Licence Conditions Handbook [B.1-3] also includes the transitional provisions to N285.0-08 (including Updates No. 1 and No. 2) [B.1-2]. It states:

> *OPG governance (pressure boundary procedures and manual) will be compliant with CSA N285.0-08 with Update #2 before October 30, 2013.* (It also provides conditions for various deliverables, e.g. design modifications and purchase orders).

Gap analyses were performed to assess the changes required to governance documents as a result of the transition to CSA N285.0-08 (including Updates No. 1 and No. 2) [B.1-2]. Reference [B.1-31] documents the changes applicable to N-PROG-MP-0004 [B.1-27] and the associated reference procedures due to the transition. All of the assignments against the Action Request (AR) referenced in this memorandum are now complete (see AR #28154550, "Transition Project – Update Governance to Align with License Requirements").

Given the above, only the changes made to N285.0 since the 2008 (including Updates No. 1 and No. 2) [B.1-2] version need to be reviewed. These changes are reviewed along with an assessment of their impact on PSR2.

The CSA Impact Statement notification for CSA N285.0-12 [B.1-4] identifies the following changes from the previous edition (N285.0-08 (including Updates No. 1 and No. 2) [B.1-2]):

1. *Clarifies the appropriate rules to be used for process systems (such as classification) and the rules to be used for piping systems (such as the ASME rules)*

2. *Revised the term "Contractor" to "Certificate Holder", thereby clarifying that the organizations performing pressure boundary work must hold an appropriate Certificate of Authorization for the work in accordance with Clause 10 (General Requirements for Quality Assurance).*

3. *Clause 5: The rules for classification were revised to clarify the requirements and provide the information in a more logical sequence.*

4. *Clause 7: The rules for Design were revised to address the following:*

    a. *Clarify the requirements and provide the information in a more logical sequence.*

    b. *Migration of the requirement of the CNSC R-77 document into the CSA standard.*

5. *Clause 10: Significant re-write and revision of the clause to address RFI's received by the Technical Committee and to clarify and simplify the specific QA requirements for pressure boundary activities.*

6. *Annex A – Classification: This change was made to address the following:*

    a. *Clarification of the classification requirements for the Emergency Core Cooling System.*

    b. *Provide rules for determining classification of Class 3 vs. Class 6 systems based on a consequence of failure analysis.*

7. *Annex E – Implementation of Quality Assurance Programs: The Annex was deleted.*

The impact of the changes to N285.0-12 [B.1-32], were reviewed in an OPG Memorandum, N-CORR-00590-0455367, "Code Over Code Review of: CSA N285.0-12 over CSA N285.0-08 and Update #2" [B.1-33]. This memorandum concluded that there were no significant changes with respect to pressure boundary integrity. Therefore, these changes have no impact on PSR2.

A CSA Impact Statement could not be found for changes made in the N285.0-12 (including Update No. 1) [B.1-24] version in comparison to N285.0-12 [B.1-32]. However, these changes are documented in N-REP-00590-0520105, "Code over Code Report: CSA N285.0/CSA N285.6 Series For Year 2014" [B.1-34]. The report documents that except for one change, the changes are not significant. Clause 15 introduces a new requirement for the licensee to have a pressure boundary program document per the requirements in Annex N and submit it to the regulator. This was previously identified in the Darlington PSR1 discussion in Section B.1.2.1, which documents that this requirement was satisfied programmatically, and thus is not a PSR2 gap.

Changes made in N285.0-12 (including Update No. 1 and No. 2) [B.1-1] relative to N285.0-12 (including Update No. 1) [B.1-24] are paraphrased from the related Impact Statement for Publication [B.1-5] as follows:

1. *ASME OM code requirements (Clause 13.3) were clarified to reflect the graded approach adopted by the Technical Committee in accordance with the SAME OM Code and only requires those overpressure protection devices within the scope of the ASME OM Code to be addressed.*

2. *Changes related to nuclear supports in order to clarify and align with ASME III requirements for inspection during fabrication of nuclear class supports. ASME support manufacturers can fabricate ASME certified nuclear class supports without inspection by an Authorized Nuclear Inspector (ANI), in accordance with NF-8100.*

The impact of the changes was reviewed in OPG Report N-REP-00590-0526911, "Code Over Code Review Report: CSA N285.0 For Year 2015" [B.1-35]. This report concluded that there were no significant technical changes and therefore there is no impact on PSR2.

B.1.3 Compliance Summary for Pickering PSR2

There are two PSR2 CSA N285.0-12 (including Updates No. 1 and No. 2) [B.1-1] gaps which relate to Safety Factor 1 (Plant Design):

1. Clause A.2.3.1 of CSA N285.0-06 identifies that for Shutdown Systems, pressure-retaining portions shall be classified as Class 1, except for three listed exceptions. It was identified during the Pickering B Integrated Safety Review (ISR) that a limited number of Liquid Injection Shutdown System (LISS) components, which should have been Class 1, were purchased and installed as Class 3. In follow-up, OPG proposed four actions to address the deficiency. When refurbishment was not pursued, a code classification concession was accepted for continued operations. This code classification concession and the four actions identified in the Pickering B ISR gap resolution need to be reconsidered in the context of operation of Pickering NGS beyond 2020. Therefore, this has been identified as a PSR2 gap.

2. The Pickering A Return to Service review against CSA-N285.0-95 [B.1-9] identified two Acceptable Deviations relating to Clause 7.0 requiring confirmation that the allowable cycles for fatigue would not be exceeded. For Pickering Units 1,4 and Units 5-8 operation beyond 2020, further confirmation is required that the allowable cycles for fatigue will continue to bound current service limits for extended operation. Therefore, this has been identified as a PSR2 gap.

B.2 CSA N293-12, "Fire Protection for Nuclear Power Plants"

B.2.1 Background

The following, extracted from the Scope of CSA N293-12 [B.2-1], provides a brief overview of the purpose of the standard and the requirements expressed therein:

> *This Standard provides the minimum fire protection requirements for the design, construction, commissioning, operation, and decommissioning of nuclear power plants, including structures, systems, and components (SSCs) that directly support the plant and the protected area.*

CSA N293 is relevant to Safety Factor 1 (Plant Design) and Safety Factor 7 (Hazard Analysis). CSA N293 is also relevant to Safety Factor 13 (Emergency Planning), since the CNSC Acts and Regulations webpage [B.2-2] identifies the Standard as being relevant to the Safety Control Area for "Emergency Management and Fire Protection".

Compliance with CSA N293-07 [B.2-3] is currently a licence requirement for Pickering NGS (PROL 48.02/2018) as indicated in Section 11.2 and Appendix C.1 of the R04 Pickering Licence Conditions Handbook [B.2-4].

CSA N293-12 is the fourth edition of this standard, and supersedes the previous editions published in 1987, 1995 and 2007. The CSA N293-12 Impact Statement [B.2-5] identifies the significant changes between the 2012 and 2007 editions of the Standard, which are discussed in Section B.2.2.2 below.

The results of PSR1 CSA N293 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.2.2. As identified in Reference [B.2-6], the Pickering PSR2 review of CSA N293-12 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- <u>Compliance:</u> Compliance indicates that the change in the safety requirement, per the topical review, is met.
- <u>Gap</u>: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.2.2 Compliance Assessment for Pickering PSR2

B.2.2.1 Application of PSR1 Reviews

The versions of N293 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

As part of the Pickering B ISR, OPG Report NK30-REP-03680-00005 R000, "Pickering NGS B Integrated Safety Review - Safety Analysis Review" [B.2-7] assessed CSA N293-95 [B.2-8] and stated:

> *An overall program N-PROG-RA-0012 has been established to manage Fire Protection at OPG plants …* [which] *… describes the Nuclear governing documents intended to achieve the fire protection goals of CSA N293-95. N293-95 deals with all aspects of fire protection at a programmatic level…. It is concluded that OPG complies with the requirements of CSA standard N293-95 and the compliance is built into existing governance, so there is no expected impact on Pickering B plant life extension in terms of this version of the CSA standard.*

The scope of OPG Program N-PROG-RA-0012 R011, "Fire Protection" [B.2-9] is as follows:

> *This program outlines the scope and objectives of documentation that comprises the fire protection program and interfacing programs for Ontario Power Generation Nuclear… It describes the fire protection organization, interfacing organizations, and their fire protection accountabilities. These processes and organizations are required to minimize the risks and consequences of fire to Nuclear in accordance with: - Nuclear Power Reactor Operating License (PROL) requirements… - Canadian Standards Association (CSA) N293, Fire Protection for Nuclear Power Plants.*

OPG Report NK30-REP-03680-00001 R000, "Pickering NGS-B Integrated Safety Review - Plant Design Safety Factor" [B.2-10] performed a clause-by-clause review of N293-95 [B.2-8] against Safe Operating Envelope (SOE) systems / Systems Important to Safety (SIS) and found ten gaps, of which four were classified as Discrepancies and six as Acceptable Deviations (Note: OPG Report NK30-REP-03680-00001 R000 [B.2-10] did not assess the Pickering B Fire Protection System specifically as part of the review, as it was not classified as an SOE or SIS system). The six Acceptable Deviations were grouped as Issues 1-040/042/043/047/048/049 [B.2-11]. The four Discrepancies were:

- 1-045: Clauses 5.2.5 (d) - *SOE systems containing hydrogen/deuterium not reviewed against NFPA 50A.*
- 1-046: Clause 6.3.5 - *No specific statement to consider deleterious effects of discharging extinguishing agents on equipment in fire area (flooding, additional loads, cooling, etc.).*
- 1-050: Clause 7.5.2 - *No assessment made of SOE/SIS system components that contain flammable liquids/gases and are not seismically qualified.*
- 1-062: Clause 6.5.2 - *Providing holes or doors for discharging extinguishing agents into enclosures/electrical cabinets was not a design requirement.*

OPG Letter, "Pickering NGS-B Integrated Safety Review - Discrepancy Resolution" [B.2-12] stated that the four Discrepancies (1-045, 1-046, 1-050, 1-062) were being resolved by the implementation of a Corrective Action Plan (CAP) for SCR P-2007-17722, and that no further action was required. The CNSC accepted the four Discrepancy classifications, but requested that more information be provided on the six Acceptable Deviations [B.2-11]. The CNSC further responded [B.2-13] by requesting that OPG provide additional justification that no further action is required as part of life extension. OPG Report NK30-REP-03680-00016 R000, "OPG Response to CNSC Comments on Pickering NGS-B Integrated Safety Review - Plant Design, Safety Analysis, Safety Performance, Ageing and Equipment Qualification Safety Factors and Discrepancy Resolutions" [B.2-14] dispositioned the Acceptable Deviations and Discrepancies as low or very low significance with any follow-up work captured under Issue 1-643. OPG Report NK30-REP-03680-00015 R000, "Pickering NGS-B Integrated Safety Review (ISR) - Final ISR Report" [B.2-15] documented the OPG disposition to Issue 1-643 by stating that "OPG will perform a review of CSA N293-07." The commitment to perform a review of CSA N293-07 was later completed as discussed below.

Before discussing the results of the CSA N293-07 review, it is noted that a fire protection Code Compliance Review (CCR) was performed for Pickering B in 2000 to demonstrate that an adequate level of fire protection is provided for the station. The 2000 CCR was documented in OPG Report NK30-REP-71400-10001 R000, "Fire Protection Code Compliance Review Pickering Nuclear Generating Station B" [B.2-16] and assessed compliance of Pickering B with the requirements of the National Building Code of Canada (NBCC), National Fire Code of Canada (NFCC) and applicable National Fire Protection Association (NFPA) standards. The 2000 CCR was later "updated and upgraded" in 2010 to reflect CSA N293-07 requirements and current plant configuration in OPG Report NK30-REP-71400-10001 R001, "Fire Protection Code Compliance Review Pickering Nuclear Generating Station B" [B.2-17].

A gap analysis was performed and documented prior to initiating the 2010 CCR update, per OPG Report NK30-REP-71400-0299410 R000, "Fire Safety Assessment: Definition of Scope of Work for CSA N293-07 Compliance at PNGS-B" [B.2-18]. As part of the gap analysis, changes between the 1995 and 2007 editions of CSA N293 deemed to impact the CCR were identified. The gap analysis concluded that the changes between the 2007 and 1995 editions of N293 and other standards referenced therein "have no impact on the existing physical features of the station, as they are not intended to be applied retroactively. They would as such, be applicable only to new construction including modifications undertaken at the station subsequent to adoption of the new codes and standards under the site operating license." The gaps identified between N293-95 vs N293-07 were related to Inspection, Testing, and Maintenance (ITM) with no impact on the design/construction portion of the CCR. The original 2000 CCR included an assessment of the ITM requirements that applied to the fire alarm life safety systems at Pickering B. The updated ITM evaluation was removed from the CCR and was addressed under OPG Reports NK30-REP-71400-00018 R000, "Fixed Fire Protection Systems Inspection, Testing and Maintenance" [B.2-19] and NK30-REP-71400-00027 R000, "Third Party Review: Fixed Fire Protection Systems Inspection, Testing and Maintenance Report" [B.2-20]. The objective of the Third Party Review [B.2-20] was to assess OPG's evaluation of the ITM program as it applies to fixed fire protection systems at Pickering B for "compliance with the requirements of applicable codes and standards and other relevant documents referenced therein", which included N293-07 [B.2-3]. The Third Party Review [B.2-20] resulted in the identification of 79 deviations from applicable codes and standards. There were three Deviations specifically related to N293-07 as discussed below (text taken verbatim is in italics):

- N293-07 Clause 8.3.3.1 (a) (Deviation No. 73): *Description - Combustible-material-free fire zones must be inspected daily to ensure that they are free of combustible materials. OPG Disposition - Inspection strategy for direct compliance will be implemented prior to operational compliance.* [Third Party Reviewer] *Concurrence - Accepted, Item Closed.*

- N293-07 Clause 8.3.3.1 (c) (Deviation No. 74): *Description - Area with high fire hazards and fire sensitive area must be inspected daily. OPG Disposition - Inspection strategy for direct compliance will be implemented prior to operational compliance.* [Third Party Reviewer] *Concurrence - Accepted, Item Closed.*

- N293-07 Clause 8.3.3.1 (d) (Deviation No. 75): *Description – Doors identified as fire barriers in the FSSA [Fire Safe Shutdown Analysis] must be inspected weekly. OPG Disposition - Currently, PNGS-B complies with CSA N293-95 as per licensing agreement. Inspection strategy is currently being developed as part of the CSA N293-07 implementation project. A list of performance barrier doors has been prepared. Once the list is approved, recommended inspection frequency will be monthly. AHJ [Authority Having Jurisdiction] approval will have to be obtained for frequency change.* [Third Party Reviewer] *Concurrence - Accepted, Item Closed.*

OPG Report NK30-REP-71400-00027 R000 [B.2-20] states that "a satisfactory disposition has been reached to resolve all noted Deviations." Furthermore, as discussed below, Pickering Units 5-8 compliance with the operational requirements of CSA N293-07, including ITM Deviations, has since been demonstrated.

OPG Report NK30-REP-71400-00033 R000, "Pickering NGS 058 Compliance with CSA N293-07, Fire Protection for CANDU Nuclear Power Plants" [B.2-21] was completed to assess compliance against the operational requirements of N293-07, and no gaps were identified. NK30-REP-71400-00033 R000 states:

> *Based on the information provided in this report, Pickering 058 is in compliance with the operational requirements of CSA N293-07. The fire protection design basis documents listed below were all submitted in NK30-CORR-00531-05774, Letter G. Jager to M. Santini, "Pickering NGS 'B' – Request for CNSC Acceptance of the CCR, the Third Party Review of the Inspection, Testing and Maintenance Report for Fixed Fire Protection Systems, the FSSA and the FHA [Fire Hazard Assessment]", December 9th, 2011* [B.2-22].
>
> - *NK30-REP-71400-10001 R001, Fire Protection Code Compliance Review Pickering Nuclear Generating Station B* [B.2-17]
> - *NK30-REP-71400-10002 R002, Fire Hazard Assessment – Pickering B Nuclear Generating Station* [B.2-23]
> - *NK30-REP-71400-00001 R002, Fire Safe Shutdown Analysis – Pickering B Nuclear Generating Station* [B.2-24]
> - *NK30-REP-71400-00027, Third Party Review Fixed Fire Protection Systems Inspection Testing And Maintenance* [B.2-20]

These documents were accepted by the CNSC as satisfying the intent of submission in NK30-CORR-00531-06167, Letter M. Santini to G. Jager, CNSC Acceptance of the Fire Hazard Assessment, Fire Safe Shutdown Analysis, Code Compliance Review and the Inspection Testing and Maintenance Report for Fixed Fire Protection Systems [B.2-25]*. A technical assessment conducted by CNSC Fire Protection staff for all documents submitted is ongoing. Any issues or questions identified following this technical assessment will be addressed as they are received. Tracking of any outstanding deviations identified in the fire protection design basis documents listed above follows the normal Regulatory process.*

In addition to the above, it is noted that OPG List P-LIST-71400-00001 R000, "Application of CSA N293-07 to Structures, Systems and Components for Pickering Nuclear" [B.2-26] was prepared (and referenced in NK30-REP-71400-00033 R000 [B.2-21]) to identify the SSCs within the protected area that are exempt from the application of N293-07, and the structures outside the protected area that need to follow N293-07. Further, OPG Plan P-PLAN-09100-00001 R003, "Pickering Fire Safety Plan" [B.2-27] provides a description of the fire protection initiatives in place at Pickering NGS. Per P-PLAN-09100-00001 R003, "The intent of the Pickering Nuclear Fire Safety Plan is to: - Protect the plant and its staff from hazards and fires. – Minimize the interruption of power generation due to fires. – Minimize economic loss resulting from fire damage. – Minimize the risk of a fire". P-PLAN-09100-00001 R003 states that the Fire Safety Plan meets the requirements of N293-07.

Based on the above, there are no PSR2 gaps associated with the Pickering B ISR review, or subsequent CCR, which assessed compliance against CSA N293-95 [B.2-8] and N293-07 [B.2-3]. OPG Letter NK30-CORR-00531-06731 R000, "Pickering Units 5-8 - Status Update on CSA N293-07 Outstanding Items List" [B.2-28] and NK30-PLAN-00531-00001 R005, "Pickering 5-8 Continued Operations Plan" [B.2-29] subsequently confirmed successful completion of all remaining Deviations identified against N293-07. These past dispositions are not impacted by Pickering NGS operation past 2020.

Nevertheless, NK30-REP-71400-00033 R000 [B.2-21] did not review the design requirements of N293-07, given that Clause 4.3.1 of N293-07 states:

General application: This Standard applies to all plants where its requirements are referenced as a licence condition by the AHJ. For facilities licensed for construction prior to the publication of this Standard, (a) the design and construction requirements of this Standard shall not be retroactively applied to existing structures, systems, and components; and (b) the operational requirements (e.g., general requirements, concepts, programs, operations, analyses, emergency response) of this Standard shall apply.

As a result, NK30-REP-71400-00033 R000 [B.2-21] states that:[5]

---

[5] One of the significant differences between the 1995 and 2007 versions of N293 was the acknowledgement that the design and construction requirements of N293 do not apply to those plants that were licensed before January 2007. Therefore, in the absence of modification, existing plants are not required to retro-actively upgrade facilities to demonstrate compliance with this standard.

As per Clause 4.3.1, design requirements do not apply retroactively to existing facilities. For new designs [i.e., plant modifications]*, see information under Clause 4.3.2 regarding the integration of CSA N293-07 in the ECC [Engineering Change Control] process. Fire protection program implemented as per fire protection program N-PROG-RA-0012* [B.2-9] *and its governing procedures.*

The disposition for Clause 4.3.2 states:

The following documentation was either revised or created to align the CSA N293-07 requirements to the existing modification process:

- *N-PROC-MP-0090, Modification Process* [B.2-30]
- *N-GUID-00700-10000, Guide to Modification Process* [B.2-31]
- *N-FORM-10287, Fire Protection Impact Evaluation* [B.2-32]
- *N-STD-RA-0038, Requirements of Fire Safety Assessments* [B.2-33]
- *N-GUID-09076-10002, Guide to Fire Protection Requirements for Design Modifications* [B.2-34]
- *N-INS-09076-10004, Fire Protection Third Party Review* [B.2-35]
- *N-FORM-11180, Fire Codes and Standards Compliance Record* [B.2-36].

OPG Guideline N-GUID-00590-00002 R001, "Code over Code Review – Guideline" [B.2-37] and OPG List N-LIST-00590-00001 R002, "List of Significant Technical Changes from Code-Over-Code Review" [B.2-38] together ensure that any future design changes made to the Pickering NGS Fire Protection System comply with the latest version of N293.

Pickering NGS compliance against the design requirements of N293-07, as well as the changes in N293-12 [B.2-1], is addressed in Section B.2.2.2 below.

<u>Pickering Units 1,4</u>

OPG Letter NA44-CORR-00531-00381 R000, "Pickering A - Updated Basis for Return to Service Document" [B.2-39], Attachment "Pickering A - Basis for Return to Service", noted that the Atomic Energy Control Board requested that OPG review fire protection at Pickering A against CSA N293-95 [B.2-8]. OPG subsequently performed a clause-by-clause review of N293-95 in OPG Report NA44-REP-71400-10004 R000, "PNGS-A Compliance to CSA N293-95, Fire Protection for CANDU Nuclear Power Plants" [B.2-40] as part of the Fire Safety Assessment (FSA) under the OPG Fire Protection Upgrade Project (IIP EN-008). OPG Report NA44-REP-71400-10004 R000 [B.2-40] states:

[The review assessed]*… the design of Pickering 'A' against the requirements laid out in CSA N293-95 on Fire Protection. As the goal is to identify the requirements that were not known at the time these units were designed, compliance discussion for each requirement is based on finding existence of the requirement in plant documents, or current commitment to implement the requirement, and if such evidence is not available, on reviewing the as-built design to determine if the requirement was implemented…*

This review concludes that following completion of the upgrades being implemented during the Pickering 'A' Return to Service, the design of Pickering 'A' will meet the intent of all requirements of CSA N293-95 and that no further changes are necessary.

Pickering A was deemed to be in either Indirect or Direct Compliance, or "Non-Compliant Acceptable", with the various clauses of N293-95 (note: the Non-Compliant Acceptable clauses generally related to the use of High Pressure Service Water (HPSW) for firewater at Pickering A, which has since been replaced by diesel firewater pumps per OPG Letter NA44-CORR-00531-06269 R000, "Pickering "A" - Installation of Diesel Engine Driven Fire Pumps (MEC 91665)" [B.2-41]). These past dispositions are not impacted by Pickering NGS operation past 2020. The review further stated that, as part of the Pickering A Return to Service Fire Protection Project at the time, Pickering A had committed to installing upgraded fire detection and suppressions systems in four locations within each unit, in particular the Main Control Room, Control Equipment Rooms, Cable Spreading Areas and Turbine Generator Areas.

A fire protection CCR was prepared in 2000 in OPG Report NA44-REP-71400-10001 R000, "Pickering Nuclear Generating Station "A" Fire Protection Code Compliance Review" [B.2-42] to demonstrate compliance of Pickering A with the requirements of the NBCC, NFCC and applicable NFPA standards. The original 2000 CCR was updated in 2011 to reflect current station conditions and N293-07 requirements, as outlined in OPG Report NA44-REP-71400-10001 R001, "Pickering NGS A Fire Protection Code Compliance Review (CCR)" [B.2-43].

A gap analysis was also performed and documented prior to initiating the 2010 CCR update, per OPG Report, NA44-REP-71400-0300967 R000, "Fire Safety Assessment: Definition of Scope of Work for CSA N293-07 Compliance at PNGS-A" [B.2-44]. As part of the gap analysis, changes between the 1995 and 2007 editions of CSA N293 deemed to impact the CCR were identified. The gap analysis concluded that the changes between the 1995 and 2007 editions of N293 and other standards referenced therein "have no impact on the existing physical features of the station, as they are not intended to be applied retroactively. They would as such, be applicable only to new construction including modifications undertaken at the station subsequent to adoption of the new codes and standards under the site operating license. Changes to the N293 standard were also identified as having an impact on the operations of the station. These changes and associated impacts will be addressed in the FHA for the station." Similar to the equivalent Pickering B review, the Pickering A gaps identified between N293-95 and N293-07 were related to ITM, with no impact on the design/construction portion of the CCR.

The ITM evaluation was addressed under OPG Reports NA44-REP-71400-00021 R000, "Pickering A Fixed Fire Protection Systems Inspection, Testing, and Maintenance Code Compliance Report" [B.2-45] and NA44-REP-71400-00022 R000, "Third Party Review: Fixed Fire Protection Systems Inspection, Testing and Maintenance Report" [B.2-46]. The objective of the Third Party Review was to assess OPG's evaluation of the ITM program as it applies to fixed fire protection systems at Pickering A for "compliance with the requirements of applicable codes and standards and other relevant documents referenced therein", which included N293-07. The review of OPG's compliance evaluation resulted in the identification of 91 Deviations from applicable codes and standards. There were three Deviations specifically related to N293-07 which were associated with the same clause (Clause 8.3.3.1 (a), (b) and (d)) assessed as Deviations for Pickering B which were discussed earlier. NA44-REP-71400-00022 R000 [B.2-46] states that "a satisfactory disposition has been reached to resolve all noted Deviations."

Furthermore, as discussed below, Pickering Units 1,4 compliance with the operational requirements of CSA N293-07, including ITM Deviations, has since been demonstrated.

OPG Report NA44-REP-71400-00027 R000, "Pickering NGS 014 Compliance with CSA N293-07, Fire Protection for CANDU Nuclear Power Plants" [B.2-47] was completed to assess compliance against the operational requirements of N293-07, and no gaps were identified. NA44-REP-71400-00027 R000 states:

> *Based on the information provided in this report, Pickering 014 is in compliance with the operational requirements of CSA N293-07. The fire protection design basis documents listed below has been submitted to the CNSC as per the referenced correspondence.*
>
> - *NA44-REP-71400-10001 R001, Fire Protection Code Compliance Review Pickering Nuclear Generating Station A* [B.2-43]
> - *NA44-REP-71400-00022, Third Party Review, Fixed Fire Protection Systems Inspection, Testing and Maintenance* [B.2-46]
>
> *Both submitted in NA44-CORR-00531-06690, Letter G. Jager to M. Santini, Pickering A – Request for CNSC Acceptance of [the] Fire Protection Code Compliance Review, and Third Party Review, Fixed Fire Protection Systems Inspection, Testing and Maintenance, June 21st, 2011.*
>
> - *NA44-REP-71400-10003 R001, Fire Hazard Assessment – Pickering A Nuclear Generating Station* [B.2-48]
> - *NA44-REP-71400-00023 R000, Fire Safe Shutdown Analysis – Pickering A Nuclear Generating Station* [B.2-49]
>
> *Both submitted in NA44-CORR-00531-06935, Letter G. Jager to M. Santini, Pickering NGS 'A' – Request for CNSC Acceptance of the "Fire Safe Shutdown Analysis" (FSSA) and "Fire Hazard Assessment" (FHA) Reports and Status Update on CCR/ITM Deviations, June 28th, 2012* [B.2-50]. *The submission of all documents listed above was acknowledged by the CNSC in NA44-CORR-00531-06992, Letter M. Santini to G. Jager, Pickering NGS-A – Fire Safe Shutdown Analysis and Third Party Review, Fixed Fire Protection Systems Inspection, Testing and Maintenance* [B.2-51]. *This letter accepted the proposed completion actions and timeline for deviations identified in the reports and stated that a more detailed technical review of the submission was ongoing. Any further requests for information or clarification identified as a result of this review will be addressed as they are received.*

OPG Letters NA44-CORR-00531-06837 R000, "Pickering NGS A - CNSC Acceptance of Fire Protection Code Compliance Review and Third Party Review, Fixed Fire Protection Systems Inspection Testing and Maintenance" [B.2-52] and NA44-CORR-00531-07475 R000, "Confirmation of Completion of CSA N293-07 Outstanding Items List Pickering NGS 'A'" [B.2-53] subsequently confirmed successful completion of all remaining Deviations identified against N293-07. Based on the above, there are no PSR2 gaps associated with the Pickering A Return to Service review against N293-95 [B.2-8], or the subsequent CCR which addressed compliance against the operational aspects of N293-07 [B.2-3].

OPG Guideline N-GUID-00590-00002 R001 [B.2-37] and OPG List N-LIST-00590-00001 R002 [B.2-38] together ensure that any future design changes made to the Pickering NGS Fire Protection System comply with the latest version of N293.

As noted for the Pickering B review against N293-07, NA44-REP-71400-00027 R000 [B.2-47] did not review the design requirements of N293-07 as they are not applicable to an existing facility. As a result, Pickering NGS compliance against the design requirements of N293-07, as well as the changes in N293-12, is addressed in Section B.2.2.2 below.

Darlington NGS

OPG Report NK38-REP-03680-10014 R000, "Review of CAN/CSA N293-07 (January 2008) Fire Protection for CANDU Nuclear Power Plants for Darlington Integrated Safety Review (ISR)" [B.2-54] documented a clause-by-clause review of the operational requirements of CSA N293-07 [B.2-3]. OPG Report NK38-REP-03680-10128 R003, "Gap Analysis to CSA N293-07 Design Clauses for the Darlington Integrated Safety Review" [B.2-55] documented a clause-by-clause review of design clauses excluded from NK38-REP-03680-10014 R000 (based on not being required as per Clause 4.3.1, which states "the design and construction requirements of this Standard shall not be retroactively applied to existing structures, systems, and components"). OPG Report NK38-REP-03680-10189 R000, "Code Review Refresh of CAN/CSA N293, Fire Protection for CANDU NPP, 2012 Edition" [B.2-56] evaluated compliance against the design requirement clauses (Sections 5, 6 and 7) of CSA N293-12 [B.2-1]. OPG Report NK38-REP-78000-10084 R000, "Darlington NGS Compliance with CSA N293-12, Fire Protection for Nuclear Power Plants" [B.2-57] documented Darlington's compliance with the operational requirements of N293-12 and stated: "The 2012 edition of CSA N293 did not introduce any significant technical changes from the 2007 edition. CSA N293-12 is written as a nuclear reactor technology neutral Standard and it incorporates clarifications and OPEX received from the Canadian licensees. Based on the information provided in this report, it is concluded that Darlington NGS is in compliance with the operational requirements of the CSA N293-12 Standard."

The Darlington ISR review findings are not discussed further due to the Pickering Units 1,4 and 5-8 N293-07 reviews above, and the N293-07 and N293-12 compliance discussions provided under Section B.2.2.2 below. However, the content of the above mentioned Darlington ISR Reports was utilized in Section B.2.2.2 below to assist in ascertaining Pickering NGS compliance against the 2007 and 2012 editions of CSA N293.

B.2.2.2 Application of Post PSR1 Reviews

Per the CSA N293-12 Impact Statement [B.2-5], the following is a summary of the significant changes from the previous edition of the standard (N293-07 [B.2-3]):

1. *Changed… to be "Technology Neutral" such that it can now be applied to any type of nuclear power plant, not just CANDU plants.*

2. *Incorporated lessons learned following the introduction of the standard into the Canadian regulatory framework, to facilitate its application as a licensing requirement to existing and future plants.*

3. *Added the collective term "Fire Protection Assessments (FPA)" to include the Code Compliance Review (CCR), the Fire Hazard Assessment (FHA), and the Fire Safe Shutdown Analysis (FSSA), and clarified the requirements for each.*

4. *Incorporated changes to address issues arising from Requests for Interpretation (RFI) during the implementation of N293-07.*

5. *Continued the move toward an objective based standard by maintaining the separation between the fire protection goals, objectives and criteria (Chapter 5) and the requirements for their implementation (Chapters 6 to 11). This will assist the user of the standard in identifying suitable alternatives to the requirements which meet the stated goals, objectives and criteria.*

6. *Protection of the environment was added as an additional goal for fire protection in Chapter 5. Although no additional implementation requirements have been added, the user of the standard must consider the effects on the environment of all fire protection measures (e.g., releases of radioactive materials, chemicals, hydrocarbons, etc.).*

7. *The use of the term "listed" as it pertains to fire protection equipment has been eliminated from the standard, being replaced by wording indicating that equipment must be suitable for its intended use. Although in most cases, the use of "listed" equipment would be the means of providing suitable equipment, it would not be the only means of satisfying the requirements of the standard.*

OPG Memorandum, N-CORR-00590-0477035, "Code-over-Code Review of CSA N293, Fire Protection for Nuclear Power Plants - 2012 Edition over the 2007 Edition" [B.2-58] provides a generic nuclear review of N293-12 against N293-07. This clause-by-clause review found no significant technical changes between N293-12 and N293-07 and no mitigation required. Of note to existing stations are:

- Clause 5.2 which is "changed to include another goal pertaining to minimizing the impact of radioactive and hazardous materials on the environment as a result of fire". However, per Reference [B.2-58], the "current revisions of DNGS and PNGS FHA reports addressed safety of radioactive materials as part of their objectives". Therefore, there is no impact on current practices and assessments.

- Clause 5.6.2 which is "changed by replacing the term FSSA with Fire Protection Assessments (FPAs)". However, per Reference [B.2-58], the "current requirement to update the DNGS and PNGS FSSA/FHA/CCR remains unchanged". This change is for clarification only.

- Clause 7.3.3.5 which is "revised to include an additional requirement for cable tray protection"*.* However, per Reference [B.2-58], the "current revisions of DNGS and PNGS

FHA and FSSA reports demonstrate the fire protection goals are met. Therefore, this is not considered a significant technical change."

Although these clauses are relevant to Pickering NGS, applicable changes are addressed in the current Pickering Units 5-8 and 1,4 Fire Safe Shutdown Analyses, Fire Hazard Assessments, and/or Code Compliance Review reports. Based on the above, there are no safety significant changes resulting from CSA N293-12.

As discussed previously, compliance with CSA N293-07 [B.2-3] is currently a licence requirement for Pickering NGS (PROL 48.02/2018) as indicated in Appendix C.1 of the R04 Pickering Licence Conditions Handbook [B.2-4]. Completion of all remaining operational and ITM Deviations identified against N293-07 was confirmed by NA44-CORR-00531-07475 R000 [B.2-53] and NK30-CORR-00531-06731 R000 [B.2-28]. However, Pickering NGS compliance against the design requirements of CSA N293 was not formally documented in the past given that Clause 4.3.1 of both CSA N293-07 and N293-12 state: "the design and construction requirements of this Standard shall not be retroactively applied to existing structures, systems, and components". Since compliance review against the design requirements of CSA N293-12 was not undertaken as part of previous Pickering NGS PSR1 reviews, the following high level assessment has been completed. In the review below, the degree of conformance with clauses or groups of clauses in CSA N293-12 is assessed for Pickering NGS by reference to supporting evidence stating whether the intent of the requirements stipulated in the standard is met. The high level intent review below assessed Pickering NGS against Sections 4 (General Requirements), 5 (Fire Protection Concepts), 6 (Design Requirements) and 7 (Design and Installation Requirements) of CSA N293-12.[6]

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
4 General Requirements 4.1 Effective Date 4.2 Responsibility 4.3 Applicability to Existing Facilities 4.4 Alternatives and Performance-Based Approaches	Clause 4 of N293-12 provides general requirements for the application of the standard. Per N-REP-09076-10006 R000, "Review of Design Requirements of CSA N293-07" [B.2-59]: "Those modifications to existing plants must comply with the design requirements of this standard (applies to the modified portions only). In the event that compliance cannot be met then Clause 4 provides the mechanism for resolution of any deviation. Therefore, in the event of a modification to the plant the modified structure, system or component must either meet the deterministic, design requirements detailed in Clause 6 and Clause 7, or demonstrate an equivalent level of fire	Compliant

6 Sections 1 (Scope), 2 (Reference Publications) and 3 (Definitions and Abbreviations) were not reviewed as there are no requirements and the provided information is context-setting or background/definition/reference information only. Section 9 (Fire Protection Requirements for Decommissioning) was not reviewed as Decommissioning is not in PSR2 scope.

Sections 8 (Implementation of Fire Protection Program), 10 (Fire Response Capability) and 11 (Fire Protection Assessments) contain operational content and were previously addressed in past Pickering NGS reviews. Furthermore, there were no safety significant changes to these sections in N293-12 per N-CORR-00590-0477035 [B.2-58].

The Annexes to N293-12 are non-mandatory commentary only and a review is therefore not required.

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
4.5 Documentation Requirements for Alternatives and Performance-Based Approaches 4.6 Fire Protection Assessments	safety through equivalency or performance based approaches detailed in Clause 4." There are no safety significant changes between Clause 4 of N293-07 and N293-12 [B.2-58]. Clause 4 was reviewed for Pickering PSR2 and it was determined that all sub-clauses except the two below were addressed in prior Pickering NGS N293-07 reviews (i.e., NK30-REP-71400-00033 R000, "Pickering NGS 058 Compliance with CSA N293-07, Fire Protection for CANDU Nuclear Power Plants" [B.2-21], NA44-REP-71400-00027 R000, "Pickering NGS 014 Compliance with CSA N293-07, Fire Protection for CANDU Nuclear Power Plants" [B.2-47]).[7] • Sub-clause 4.3.1: Bullet (a) of this sub-clause states: "the design and construction requirements of this Standard shall not be retroactively applied to existing structures, systems, and components". Sub-clause 4.3.1 (a) was cited in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]) to conclude that design-related clauses did not need to be assessed. Compliance against all design related clauses of N293-12 (Sections 4-7) has been assessed as part of PSR2 in this high level intent review table, as discussed below. • Sub-clause 4.6.2: This sub-clause states: "For facilities licensed for operation prior to the publication of this Standard, the assessments referred to in Clause 4.6.1 shall demonstrate achieving (a) the goals, objectives and criteria of Clause 5; (b) the operational requirements of this standard; and (c) the applicable design and construction requirements of the codes of record. Note: It is intended by this Standard that fire protection assessments required by this Clause can be satisfied by previous analysis performed in accordance with the 2007 edition of this Standard (i.e., CCR, FHA, FSSA, etc.) and maintained in compliance with Clause 11.2.3." This sub-clause has changed from NK30-REP-71400-00033 R000 [B.2-21] and NA44-REP-71400-00027 R000 [B.2-47] to provide additional context and clarity. Although Pickering NGS is not a new facility, it does comply with N293-07 per Pickering NGS PROL requirements [B.2-4] and the information provided earlier in this review (e.g., see NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-06731 R000 [B.2-28]). CCRs ([B.2-17], [B.2-43]), FHAs ([B.2-23],	

[7] The 2015 Pickering A and B N293-07 reviews, NK30-REP-71400-00033 R000 [B.2-21] and NA44-REP-71400-00027 R000 [B.2-47], did not identify any gaps. Therefore, if a clause was previously assessed in [B.2-21] and [B.2-47], and has not been revised in N293-12, compliance was previously demonstrated and there is no PSR2 gap.

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	[B.2-48]) and FSSAs ([B.2-24], [B.2-49]) have been prepared for Pickering NGS. Furthermore, an intent review is provided against Clause 5 of N293-12 below. Therefore, there is no PSR2 gap.	
5 Fire Protection Concepts 5.1 General 5.2 Goals 5.3 Defence-in-Depth Principle 5.4 Nuclear Safety Objectives and Performance Criteria 5.5 Life Safety 5.6 Fire Protection Assessments (FPA) 5.7 General Fire Protection Measures 5.8 Fire Protection Program 5.9 Fire Protection for Modifications to Operating Plants 5.10 Quality Assurance	Clause 5 of N293-12 provides general fire protection concepts and performance level requirements for design, construction and operation. Clause 5 also provides details of the requirements for assessments to be conducted on modifications which have the potential to impact fire safety. Per N-REP-09076-10006 R000 [B.2-59], this requirement mirrors the process presently implemented by OPG Nuclear in the ECC process and stated in the Pickering PROL, i.e., that: a) the reviews are the responsibility of the plant Design Authority, b) all modifications shall be screened and those having potential for fire impact will receive a detailed review, c) those modifications screened as having potential to impact fire safety shall be submitted to a qualified third party for review and the AHJ, and d) the qualified third party must not be in the same management and financial operation as the design organization. As noted earlier, OPG Guideline N-GUID-00590-00002 R001 [B.2-37] and OPG List N-LIST-00590-00001 R002 [B.2-38] together ensure that any future design changes made to the Pickering NGS Fire Protection System comply with the latest version of N293. With respect to the individual sub-clauses: • <u>Clause 5.1</u> defines the general scope, purpose and objectives of Clause 5. This information is context setting only, i.e., there are no requirements. One minor editorial change was made in N293-12 which is not safety significant. Therefore, the intent of this clause is met and there is no PSR2 gap. • <u>Clause 5.2</u> states high level fire protection goals for the plant. Although assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]), Clause 5.2 has changed in N293-12 to include another goal (d) pertaining to minimizing "the impact of radioactive and hazardous materials on the environment as a result of fire". The Pickering NGS FHAs ([B.2-23], [B.2-48]) identified potential locations where fire may result in the release of radioactive smoke or contaminated water run-off. The FHAs determined adequate controls are in place to satisfy ALARA (As-Low-as-Reasonably-Achievable) principles and identified areas for improvement. OPG submitted the FHAs to the CNSC, noting that any identified deviations are not nuclear safety significant (per NA44-CORR-00531-06935 R000 [B.2-50], NK30-CORR-00531-05774 R000 [B.2-22]) and submitted plans for their correction which were	Compliant

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	accepted by the CNSC. These plans have now been implemented (per NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-06731 R000 [B.2-28]). The FHAs also assess the impact of fires involving hazardous materials. Therefore, the intent of new item (d) is met and there is no PSR2 gap. • Clause 5.3 addresses defence-in-depth principles. All sub-clauses were assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]) and have not been revised in N293-12, except sub-clause 5.3.2 which has changed in N293-12 to replace reference to "materials, oxidizers" with "combustible materials". This change is a clarification only. The station has policies, programs and procedures in place to reduce and control combustible materials and ignition sources per N-PROG-RA-0012 R011, "Fire Protection" [B.2-9]. Hence, the revision has no impact from a compliance perspective and the intent of this clause is met. There is no PSR2 gap. • Clause 5.4 specifies high level nuclear safety objectives and performance criteria, as well as goals for limiting the release of radioactive material and fission products. All sub-clauses were assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]) and have not been revised in N293-12, except for Clause 5.4.2.4 which has changed to replace "primary heat transport" by "reactor coolant" to make it technology-neutral, and to incorporate "moderator system" into "reactor auxiliary systems". These changes do not impact compliance. Therefore, the intent of this clause is met and there is no PSR2 gap. • Clause 5.5 specifies life safety performance objectives to be met during all operational modes and plant configurations. All sub-clauses were assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]) and have not been revised in N293-12. Therefore, the intent of this clause is met and there is no PSR2 gap. • Clause 5.6 title has changed from "Fire Safe Shutdown Analysis" to "Fire Protection Assessments" in N293-12. Sub-clause 5.6.1 has been expanded in N293-12 to require at least a CCR and a FHA along with the FSSA stipulated in N293-07. Pickering NGS has completed the CCRs ([B.2-17], [B.2-43]), FHAs ([B.2-23], [B.2-48]) and FSSAs ([B.2-24], [B.2-49]) and will continue to update them. All other sub-clauses were assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]). Therefore, the intent of this clause is met and there is no PSR2 gap.	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	• Clause 5.7 provides general fire protection measures, including control of combustible materials, control of ignition sources, fire alarm systems, fire suppression, fire hazard control, smoke management, protection against seismic hazards and control room complex. The following sub-clauses were not assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]) and/or were changed in N293-12: ○ Sub-clause 5.7.1.1 is unchanged in N293-12. This sub-clause requires that "Buildings, both in the protected area or external to the protected area but directly supporting the plant, shall be constructed using non-combustible materials, as defined in the NBCC." The Pickering A and B CCRs ([B.2-17], [B.2-43]) have examined the plant for potential deviations from use of non-combustible construction and dispositioned any findings, e.g., Deviation # 99-003 (fiberglass siding of H2 storage area) for Pickering A (per NA44-REP-71400-10001 R001 [B.2-43]), Deviation #'s 01201 and 01202 (removal of fibreglass wall panels and siding attached to H2 storage enclosures) for Pickering B (per NK30-REP-71400-10001 R001 [B.2-17]). The FSSAs ([B.2-24], [B.2-49]) have shown that a fire in any existing building would not jeopardise attaining a safe shutdown state. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. ○ Sub-clause 5.7.1.4 is unchanged in N293-12. This sub-clause requires that "Plant design shall ensure that combustible materials, dangerous goods, and liquids and gases used for plant operations are stored, located, and protected to minimize fire hazards and the resultant threats to nuclear and life safety". The Pickering NGS CCRs ([B.2-17], [B.2-43]), FHAs ([B.2-23], [B.2-48]) and FSSAs ([B.2-24], [B.2-49]) have demonstrated that design measures in place to locate and store combustible materials, dangerous goods, and liquids and gases used for plant operation adequately minimize fire hazards and the resultant threats to nuclear and life safety. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. ○ Sub-clause 5.7.2.1 is unchanged in N293-12. This sub-clause requires that "Installed devices and process operations that, by design, pose a fire hazard shall be identified and analyzed or addressed in the design stage of the plant and shall be eliminated or controlled in order to minimize the occurrence of fires". The Pickering FSSAs ([B.2-24],	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	[B.2-49]) and FHAs ([B.2-23], [B.2-48]) assessed permanent ignition sources as potential fire hazards or contributing to potential fire hazards. The consequences of these fires were assessed from a nuclear and building safety perspective. The fire safe shutdown goals were determined to be satisfied. Modifications to the plant require identification of their potential as a fire hazard and implementation of suitable mitigation as per the following plant procedures: N-PROC-MP-0090 R014, "Modification Process" [B.2-30], N-GUID-00700-10000 R015, "Guide to Modification Process" [B.2-31], N-FORM-10287 R005, "Fire Protection Impact Evaluation" [B.2-32], N-STD-RA-0038 R003, "Requirements of Fire Safety Assessments" [B.2-33], N-GUID-09076-10002 R000, "Guide to Fire Protection Requirements for Design Modifications" [B.2-34], N-INS-09076-10004 R002, "Fire Protection Third Party Review" [B.2-35] and N-FORM-11180 R002, "Fire Codes and Standards Compliance Record" [B.2-36]. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 5.7.5.1 had minor editorial changes made to two sub-clauses in N293-12 that are not safety significant. This sub-clause specifies requirements relating to layout of SSCs and separation between floors and areas within buildings. Fire safety assessments conducted over the life of the Station (i.e., Pickering NGS CCRs ([B.2-17], [B.2-43]), FHAs ([B.2-23], [B.2-48]) and FSSAs ([B.2-24], [B.2-49]) have demonstrated that the fire protection goals of CSA N293 are satisfied for the existing plant. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 5.7.5.2.2 is unchanged in N293-12. This sub-clause requires that "The turbine generator building (hall) shall be designed and separated from other areas of the plant such that a fire involving the turbine generator area will not (a) spread to other areas; and (b) result in progressive structural collapse." The 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]) note that the CCRs and FHAs have evaluated separation between the turbine building and adjacent areas, and turbine generator sprinkler protection. All recommendations of the Fire Protection Assessment reports have been implemented or dispositioned (per NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-06731 R000 [B.2-28]).	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	Therefore, the intent of this sub-clause is met and there is no PSR2 gap. ○ Sub-clause 5.7.8.1 is unchanged in N293-12 (Note that N293-07 sub-clause 5.7.8.1 was deleted as redundant, so 5.7.8.2 to .5 in N293-07 are now 5.7.8.1 to .4 in N293-12). This sub-clause requires that the "control room complex shall be separated from adjoining areas by a fire separation with a fire resistance rating as specified in Clause 6.7.1.1." This clause simply points to sub-clause 6.7.1.1 and does not, itself, require review for compliance. Sub-clause 6.7.1 is addressed specifically below. There is no PSR2 gap. ○ Sub-clause 5.7.8.2 is unchanged in N293-12, except that it has been re-numbered to 5.7.8.3. This sub-clause requires that "Special consideration shall be given to the prevention of fires in the control room complex." The sub-clause was assessed as compliant in the Pickering B N293-07 review [B.2-21] since "Impact of fires on the MCR [Main Control Room] envelope has been assessed in the updated FHA report (NK30-REP-71400-10002 R002 [B.2-23]). As there were no deviations reported, the station may be considered in compliance with this clause." Although this sub-clause was not reviewed in past reviews of Pickering A against the requirements of N293-07, the compliance basis for Pickering B is equally applicable to Pickering A as a FHA has been conducted for Pickering A as well and all its recommendations implemented or dispositioned per NA44-CORR-00531-07475 R000 [B.2-53], similar to that for Pickering B per NK30-CORR-00531-06731 R000 [B.2-28]. Thus, the intent of this sub-clause is met for both Pickering Units 1,4 and Units 5-8 and there is no PSR2 gap. • Clause 5.8 specifies Fire Protection Program requirements. All sub-clauses were assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]). No sub-clauses have been revised in N293-12, except sub-clause 5.8.3 which has changed in N293-12 to replace the acronym "FHA" by "FPA" and include "combustible waste control" in housekeeping activities, and sub-clause 5.8.5 which has changed in N293-12 to replace "structures and equipment" with "SSCs". These are editorial changes and do not impact compliance. Therefore, the intent of this clause is met and there is no PSR2 gap. • Clause 5.9 specifies requirements for modifications to operating plants. All sub-clauses were assessed in the	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]). No sub-clauses have been revised in N293-12 except sub-clause 5.9.2.2 which has changed in N293-12 to replace "systems, structures, or components" with "SSCs". This is an editorial change and has no impact on compliance. Therefore, the intent of this clause is met and there is no PSR2 gap. • Clause 5.10 addresses fire protection program Quality Assurance requirements. All sub-clauses were assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]) and have not been revised in N293-12. Therefore, the intent of this clause is met and there is no PSR2 gap.	
6 Design Requirements for the Prevention and Mitigation of Fires 6.1 General 6.2 Objectives 6.3 Separation 6.4 Protection of Fire Safe Shutdown Systems and Equipment 6.5 Reducing the Spread of Fire 6.6 Life Safety 6.7 Maintaining Plant Operation During a Fire 6.8 Fire Prevention by Design	Clause 6 of N293-12 specifies design requirements to prevent fires from occurring (as well as means to limit and mitigate fires, once initiated). With respect to the individual sub-clauses: • Clause 6.1 provides general design requirements for mitigation of fires. Clause 6.1 has not been revised in N293-12, and was not assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]). However, this clause is of a general nature (context-setting) and does not require review for compliance. • Clause 6.2 requires that the plant be provided with redundant fire safe shutdown systems to ensure that nuclear safety objectives are satisfied. Clause 6.2 was not assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]). This Clause has changed in N293-12. It now references sub-clause 5.4.1 where N293-07 referenced Clause 5.4. This change is editorial, and as discussed earlier, the intent of Clause 5.4 is met (in particular, the Pickering FSSAs ([B.2-24], [B.2-49]) modelled sufficient equipment and relevant support services to satisfy the requirements of Clause 5.4.1). Analysis was done for all credible fire scenarios in fire zones where the components or cables associated with the safe shutdown equipment are located. All recommendations of the Fire Protection Assessment reports (CCRs ([B.2-17], [B.2-43]), FHAs ([B.2-23], [B.2-48]) and FSSAs ([B.2-24], [B.2-49]) have been implemented or dispositioned (per NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-06731 R000 [B.2-28]). Therefore, the intent of this clause is met and there is no PSR2 gap. • Clause 6.3 addresses separation requirements between redundant fire safe shutdown systems. The 6.3 sub-clauses that were not assessed in the 2015 Pickering A	Compliant

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	and B N293-07 reviews ([B.2-21], [B.2-47]) are discussed below: o Sub-clauses 6.3.1.1 and 6.3.1.2 are unchanged in N293-12, and are general statements regarding methods of achieving fire separation of redundant fire safe shutdown systems (i.e., context-setting only). Therefore, a review is not required. o Sub-clauses 6.3.1.3 and 6.3.1.4, which relate to fire resistance rating of separations, have been changed in N293-12 to replace the acronym "FHA" with "FPA" to clarify that fire protection program goals can be assessed not just in the FHA but also the CCR, FSSA and other assessments. Sub-clause 6.3.1.4 was not assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]). The Pickering NGS Fire Protection Assessments that have been performed include FHAs, FSSAs and CCRs ([B.2-23], [B.2-48]; [B.2-24], [B.2-49]; and [B.2-17], [B.2-43], respectively). The FSSAs have identified the fire areas/zones where redundant safe shutdown functions are located in the same plant area (fire area/zone). The FHAs then evaluated all potential fires in the area to identify situations where a single fire can impact both redundant functions due to insufficient fire resistance rating of fire separation where provided. For redundant functions that can be impacted by a single fire, corrective measures were identified to resolve the issue. The FSSAs modelled sufficient equipment and support services to demonstrate that safe shutdown can be achieved for all credible fires following the identified corrective actions. All recommendations of the Fire Protection Assessment reports have been implemented or dispositioned (per NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-06731 R000 [B.2-28]). Further, control of transient materials is governed by N-PROC-RA-0054 R015, "Control of Space Allocation for Transient Material and Extended Storage of Material within the Site" [B.2-60] and the impact of transient material on fire protection is conducted in accordance with N-GUID-09076-10001 R004, "Guideline for Fire Protection Reviews of Space Allocation and Transient Material Permits" [B.2-61]. Thus, existing barriers to fire initiation and propagation are adequate to ensure nuclear safety objectives are met. The intent of this sub-clause is met and there is no PSR2 gap.	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	○ Sub-clause 6.3.1.5 has changed in N293-12 to replace "nuclear safety" by "nuclear safety related". This change does not impact compliance. This sub-clause applies standard requirements for life safety as per NBCC sub-clause 3.1.9.1 to protect both personnel and nuclear safety related systems. The Pickering CCRs ([B.2-17], [B.2-43]) have reviewed Pickering NGS compliance with the NBCC. All recommendations of the CCR reports have been implemented or dispositioned (per NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-06731 R000 [B.2-28]). Thus, existing barriers to fire initiation and propagation are adequate to ensure nuclear safety objectives are met. The intent of this sub-clause is met and there is no PSR2 gap. ○ Sub-clauses 6.3.2.2 and 6.3.2.3, which relate to the structure housing the Turbine Generator, have not changed in N293-12 but were not assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]). The turbine building was designed based on the relevant standards at the time of construction. The FHAs and FSSAs have demonstrated the effectiveness of the combination of fire separation, fire detection and suppression (both manual and automatic). The design of the upgraded fire suppression system for the turbine generator areas in Pickering NGS has been performed consistent with the requirement for prevention of structural steel collapse, as noted in Section 4.0 of Design Manual NA44-DM-71400-00002 R000, "Fire Protection Systems (Water)" [B.2-66] and Section 3.4.1.2 of Design Manual NK30-DM-71400-00001 R006, "Fire Protection System" [B.2-68]. Turbine building roof fans are rated for smoke removal. Therefore, the intent of these sub-clauses is met and there is no PSR2 gap. ○ Sub-clauses 6.3.3.2 and 6.3.3.3, which relate to spatial separation requirements, were not assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]). Sub-clause 6.3.3.3 has changed in N293-12 to replace the acronym "FHA" with "FPA" and to clarify that fire protection program goals can be assessed not just in the FHA but also the CCR, FSSA and other assessments. Sub-clause 6.3.3.2 prohibits the use of spatial separation in lieu of firewalls for egress except inside containment. The Pickering A CCR [B.2-43] identified Deviation # 2010-505 from this requirement and stated the following: "Exiting from	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	the NE corner of the ground floor includes travel through the NE stair which is considered part of the basement floor level which does not comply with the applicable exiting requirements." However, it concluded: "However, based on the limited occupant load, limited combustible loading, the trained and knowledgeable personnel operating in the building and the special nature of the building operations, the existing arrangement does not significantly impact the level of fire and life safety in the building. Therefore, the existing arrangement is deemed acceptable." This argument also applies to Pickering B. With respect to sub-clause 6.3.3.3 (which lists additional compensatory measures where spatial separation is used), associated bullets (a) and (b) are demonstrated to be met by the FHAs and FSSAs. The FSSAs have identified the fire areas/zones where redundant safe shutdown functions are located in the same plant area (fire area/zone). The FHA then evaluated all potential fires in the area to identify situations where a single fire can impact both redundant functions. For redundant functions that can be impacted by a single fire, corrective measures were identified to resolve the issue. The FSSA modelled sufficient equipment and support services to demonstrate that safe shutdown can be achieved for all credible fires following the identified corrective actions. Bullet (c) is met by definition as the FPA only credits provided fire detection, suppression and protection measures. All recommendations of the CCR reports have been implemented or dispositioned (per NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-06731 R000 [B.2-28]). Therefore, the intent of these sub-clauses is met and there is no PSR2 gap. • <u>Clause 6.4</u> specifies requirements relating to fire safe shutdown systems and equipment, in particular the potential to damage or disable the system or its components. Clause 6.4 was not assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]). Only sub-clause 6.4.2 has changed in N293-12 to replace the acronym "FSSA" by "FPA", which is editorial. The FSSA modelled sufficient equipment and relevant support services to satisfy these requirements. Analysis was done for all credible fire scenarios in fire zones where the components or cables associated with the safe shutdown equipment are located. The completion of the FSSAs has also demonstrated that, with some	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	corrective actions implemented, a single fire will not result in loss of required safety functions as defined in sub-clause 5.4.1. New cable tray routing is designed to follow these separation requirements to the extent practical. All recommendations of the Fire Protection Assessment reports have been implemented or dispositioned (per NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-06731 R000 [B.2-28]). Therefore, the intent of this clause is met and there is no PSR2 gap. • Clause 6.5 specifies requirements for reducing the spread of fire. The sub-clauses were not assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]) and are discussed below: o Sub-clause 6.5.1 specifies requirements for storage of combustible materials (including fire resistance rating). Sub-clause 6.5.1.1 has changed in N293-12 to provide clarification on the minimum fire resistance rating required for the fire separations serving combustible material storage rooms. This change resulted in the removal of N293-07 sub-clause 6.5.1.3 which stated this same requirement. Sub-clause 6.5.1.1 sets general requirements for the design of storage rooms, and the Pickering CCRs and FHAs did not identify any non-compliance with these requirements. For sub-clause 6.5.1.2, the adequacy of storage of combustible fluids was evaluated during the CCRs. All recommendations of the CCR reports have been implemented or dispositioned (per NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-06731 R000 [B.2-28]). Therefore, the intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 6.5.2 specifies requirements for fire stopping. All sub-clauses are the same as N293-12, except 6.5.2.1 which has changed in N293-12 to add structural supports to the list of penetration examples. FHAs and CCRs were completed for Pickering NGS which meet the requirements of N293-07. These assessments indicated that, at almost all locations of the plant, there is an appropriate combination of fire prevention, fire detection and suppression, and provisions for limiting or mitigating the effects of fire. Modifications to each unit have been made to correct any exceptions. All recommendations of the Fire Protection Assessment reports have been implemented or dispositioned (per NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	06731 R000 [B.2-28]). Further, information on fire stops is available in various Pickering NGS documentation and is utilized and cited as required in the CCRs ([B.2-17], [B.2-43]), FHAs ([B.2-23], [B.2-48]) and FSSAs ([B.2-24], [B.2-49]). These assessments demonstrate the fire stops adequately limit fire propagation so nuclear safety objectives are met. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 6.5.3 specifies requirements for layout of cable trays, and is unchanged in N293-12. The FSSAs ([B.2-24], [B.2-49]) have identified locations where additional separation or protection was required between cable trays. Modifications have been implemented to resolve identified deficiencies as required. All recommendations of the Fire Protection Assessment reports have been implemented or dispositioned (per NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-06731 R000 [B.2-28]). Further, the CCRs, FHAs and FSSAs demonstrate that cable trays and risers are located sufficiently away from fire hazards that nuclear safety objectives are met. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 6.5.4 specifies requirements for fire protection of structures, and is unchanged in N293-12. Fire protection measures are in place to protect structures, including active protection measures designed and installed in accordance with industry standards measures (e.g., turbine building), passive protection measures and operational protection measures. Similar to the compliance assessment for this clause carried out for Darlington NGS (NK38-REP-03680-10128 R003 [B.2-55]), these measures are commensurate with the reduced requirements for industrial occupancies characterized by the low density of employee population relative to offices or residential buildings. The volume of open space in the Powerhouse is such that, with the exception of the immediate fire area, the remainder of the space would not reach untenable exposure conditions for structural fire safety. Major internal fires have been analyzed for structural impact as documented in the FHAs and indicate low potential for structural damage. Therefore, the intent of this sub-clause is met and there is no PSR2 gap.	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	• <u>Clause 6.6</u> specifies requirements for life safety. The associated sub-clauses were not assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]) and are discussed below: ○ Sub-clause 6.6.1 specifies requirements for egress routes, and is unchanged in N293-12. Station airlock controls and lighting are provided power from uninterruptible power supplies with battery and standby generator back up. The Stations' standby generators, in conjunction with station batteries, provide the capability for more than 2 hours of emergency lighting. For the Pickering A CCR [B.2-43], there were no code deviations identified for emergency lighting. For the Pickering B CCR [B.2-17], modifications have been made to ensure emergency lighting levels are as per code. The adequacy of fire exits was evaluated in the CCRs. For the Pickering A CCR, two egress route Deviations requiring action were identified (#'s 2010-501 and -502). For the Pickering B CCR, five egress route Deviations requiring action were identified (#'s 03002, 03301, 05601, 2010-0501 and 2010-0502). All recommendations of the CCRs have been implemented or dispositioned (per NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-06731 R000 [B.2-28]). Therefore, the intent of this sub-clause is met and there is no PSR2 gap. ○ Sub-clause 6.6.2 specifies requirements for egress from containment structures, and is unchanged in N293-12. The adequacy of fire exits was evaluated during the Pickering A and B CCRs ([B.2-17], [B.2-43]), and no deviations requiring changes were identified. The airlocks are provided with the capability for manual operation at all times should an abnormal event such as a fire result in loss of power-assisted operation (e.g., per Design Manual NA44-21130 R000c [B.2-62]). Therefore, the intent of this sub-clause is met and there is no PSR2 gap. ○ Sub-clause 6.6.3 specifies requirements for access for firefighting, and is unchanged in N293-12. This sub-clause provides exemption from NBCC, Division B, Clause 3.2.5.1(1): "where compensatory measures acceptable to the AHJ are provided for window and access panel openings". The intent of the NBCC sub-clause in question is to ensure adequacy of response to fire. This is demonstrated by Appendix O of the FHAs ([B.2-23], [B.2-48]) which assess the capability of the Station's emergency response by the Emergency Response	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	Team (ERT). Therefore, the intent of this sub-clause is met and there is no PSR2 gap. • Clause 6.7 specifies requirements for maintaining plant operation during a fire. The associated sub-clauses were not assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]) and are discussed below. ○ Sub-clause 6.7.1 specifies requirements for the separation, smoke infiltration and contaminated air content for the control room complex, and is unchanged in N293-12. As per the Pickering A FHA [B.2-48], Section 4.4: "The results of this assessment determined that the existing barriers would provide a 2 h fire resistance rating around the MCR Complex on the 274'-0" elevation." For Pickering B, an equivalent statement is not contained in the FHA [B.2-23]. However, it is demonstrated in Appendix N of the Pickering B FHA that safe shutdown can be achieved or that fire prevention by design (e.g., qualified cables) and procedures (e.g., transient combustible controls) would prevent fire spread. Further, as discussed earlier under sub-Clause 5.7.8.2, the Pickering B N293-07 review [B.2-21] states that the "Impact of fires on the MCR [Main Control Room] envelope has been assessed in the updated FHA report (NK30-REP-71400-10002 R002 [B.2-23]). As there were no deviations reported, the station may be considered in compliance with this clause." As noted in FHA Section 4.5.1 for both Pickering A and B ([B.2-48], [B.2-23]): "Under abnormal conditions such as when smoke is detected in the control equipment rooms, the air conditioning system can be manually switched to provide smoke clearing capability from the rooms. Each control equipment room is equipped with a VESDA [Very Early Smoke Detection Apparatus] air sampling detection system that is interlocked with the air conditioning system to lock out the supply air fans upon detection of smoke, thus stopping the operation of the entire system. Following the appropriate procedures to initiate smoke clearing, the switch on the control panel can be turned to the ON position thereby initiating the return air fan." While the FHAs do not demonstrate that the MCRs will not have more than 1% of contaminated air for a 2 hour period following a fire as required by sub-clause 6.7.1.3, they state the following: "In the event that the Control Centre becomes uninhabitable due to smoke or a toxic gas, MCR	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	Uninhabitable, Abnormal Incidents Manual, NA44-AIM-014-09013-09, will be implemented to allow for an orderly planned shutdown" [B.2-48], and "a fire impacting cables and devices in the control equipment rooms would not affect the station capabilities to shut down through the UECCs [Unit Emergency Control Centres]" [B.2-23]. Thus, the Pickering MCRs are sufficiently protected in the event of a fire that nuclear safety objectives are met. The intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 6.7.2 specifies requirements for travel routes between control rooms, and is unchanged in N293-12. The concept of a secondary control room in the context of CSA N293 is taken to be the location from where fire mitigation activities would be orchestrated in the event that the MCR becomes un-inhabitable. In the case of Pickering this is the Emergency Operating Centre (EOC) located in the station's service wing. There are multiple independent means of travelling to the EOC from the MCR. Furthermore, CCRs have assessed conformance of Pickering NGS with requirements for emergency lighting. All recommendations of the CCR reports have been implemented or dispositioned (per NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-06731 R000 [B.2-28]). Therefore, the intent of this sub-clause is met and there is no PSR2 gap. • <u>Clause 6.8</u> specifies design requirements for fire prevention. The 6.8 sub-clauses that were not assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]) are discussed below: o Sub-clause 6.8.1 specifies requirements related to combustible materials in buildings and interior finishes. All sub-clauses are unchanged in N293-12, except for sub-clause 6.8.1.1 on control of combustible materials which has replaced "non-combustible materials" with the more general "non-combustible construction". Extensive evaluations have been conducted of fixed and transient combustibles on a room by room basis for the FHAs and FSSAs ([B.2-23], [B.2-48] and [B.2-24], [B.2-49], respectively). The FHAs and the FSSAs have concluded that under present conditions, the safety objectives of the Station are maintained. Evaluations of combustibles in the FHAs and FSSAs have not identified any issues related to exposed foam plastics that would adversely impact meeting	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	safety objectives. With respect to sub-clause 6.8.1.4 which relates to requirements for interior finishes, although it cannot be conclusively stated that the Station meets all the detailed requirements of this sub-clause, the Pickering NGS CCRs ([B.2-17], [B.2-43]), FHAs ([B.2-23], [B.2-48]) and FSSAs ([B.2-24], [B.2-49]) have demonstrated that the plant as built has sufficient protection from fire initiation and spread that nuclear safety objectives are met. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 6.8.2 specifies design requirements to facilitate control of transient materials, including requirements for storage and laydown areas, storage facilities and storage rooms. All sub-clauses are unchanged in N293-12, except for sub-clause 6.8.2.5 which has changed in N293-12 to incorporate improved wording for clarity. The Pickering NGS FHAs and FSSAs ([B.2-23], [B.2-48] and [B.2-24], [B.2-49], respectively) analyzed the storage rooms, laydown areas and transient combustible hazards and the potential impact on credited safe shutdown equipment. The FHAs also included a review of the Station's process controls for the use and storage of transient materials. The FHAs and FSSAs did not identify any findings regarding the storage and laydown areas at the Station. As discussed earlier, control of transient materials is governed by N-PROC-RA-0054 R015, "Control of Space Allocation for Transient Material and Extended Storage of Material within the Site" [B.2-60] and the impact of transient material on fire protection is conducted in accordance with N-GUID-09076-10001 R004, "Guideline for Fire Protection Reviews of Space Allocation and Transient Material Permits" [B.2-61]. Further, as part of the FSSAs and FHAs, combustible materials (fixed and transient) were documented on a room by room basis and fire scenarios developed to analyze the impacts and consequences of fires involving combustibles on fire safety objectives. The locations of such materials, for the purposes of the evaluations, were conservatively adjusted to achieve the greatest impact on safety. Based on the results of the evaluations, it was concluded that under the reviewed configuration, the safety objectives of the Station are met. Based on the above, the intent of this sub-clause is met and there is no PSR2 gap.	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	○ Sub-clause 6.8.3 specifies requirements for control of combustible materials in Heating, Ventilation and Air Conditioning (HVAC) equipment, including requirements for air handling ducts and combustibility of air filter media. All sub-clauses are unchanged in N293-12. With respect to air handling ducts, the basic materials of the ventilation system ductwork are galvanized sheet metal and steel plate with sheet metal joints and welded joints. These materials are non-combustible. As per the CCRs (e.g., NK30-REP-71400-10001 R001 for Pickering B [B.2-17]), the station complies with NFPA 90A-1964 item 151 (a) which states "Air filters shall be of approved types that will not burn freely or emit large volumes of smoke or other objectionable products of combustion when attacked by flames." Therefore, the intent of this sub-clause is met and there is no PSR2 gap. ○ Sub-clause 6.8.4 specifies requirements for the control of combustible materials in electrical equipment and cables, including minimizing flame spread. All sub-clauses are unchanged in N293-12, except sub-clause 6.8.4.4 which has changed to include a specific reference to Clause 4.11.4 of CSA C22.2. The FHAs ([B.2-23], [B.2-48]) indicate that at all locations of the plant there is an appropriate combination of fire prevention, fire detection and suppression, and provisions for limiting or mitigating the effects of fire. Further, the FSSAs ([B.2-24], [B.2-49]) analyzed failure of all credited electrical cabinets to assess the impact of fire on achievement of safe shutdown goals. In the event the electrical cabinets were located in a room where a hot gas layer would form, the fire impacts were assumed to result in damage of all safe shutdown credited components within the room. The results of these evaluations demonstrated that the safe shutdown goals would be met. With respect to CSA C22.2, although not all electrical cables meet the 1.5 m criterion specified in sub-clause 6.8.4.4 (e.g., 2 m for polyvinyl chloride jacketed cables past the point of flame impingement, as per Design Manual NK30-DM-57000-00001 R000, "Cabling" [B.2-63]), the cables meet Ontario Hydro test standards and are considered acceptable. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. ○ Sub-clause 6.8.5 specifies requirements for control of flammable liquids and combustible liquids. All sub-clauses are unchanged in N293-12 except for	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	numbering (which was necessary since N293-07 Clause 6.8.5 was removed in N293-12). The FSSAs and FHAs assessed the major flammable and combustible liquid hazards at Pickering NGS. Equipment containing combustible liquids was assessed for containment and potential fire spread in the FHAs and FSSAs ([B.2-23], [B.2-48] and [B.2-24], [B.2-49], respectively). The effect of an uncontrolled spill fire and a fire involving the turbine generator on FSSA-credited equipment and cables was also assessed. The results indicated that the safety goals would be met. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 6.8.6 specifies requirements for control of gases. All sub-clauses are unchanged in N293-12. Severe hydrogen/deuterium burns are prevented by design features such as: a) the Hydrogen Ignition System in containment to enable combustion of flammable mixtures at low concentrations, b) the catalytic recombination unit in the Liquid Zone System to reduce the concentration of radiolytic hydrogen in the helium to an acceptable level, and c) recombination units and flame arrestors in the moderator cover gas system. Further, compressed gas cylinders and piping were analyzed as part of the Pickering NGS CCRs ([B.2-17], [B.2-43]) from a life safety perspective and in the FHAs/FSSAs ([B.2-23], [B.2-48] and [B.2-24], [B.2-49], respectively) from a nuclear safety perspective. Based on the design, locations and safe storage arrangements, no discrepancies were identified from these assessments. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 6.8.7 specifies requirements for bulk storage of dangerous goods. This sub-clause is unchanged in N293-12. The Pickering NGS CCRs and FHAs reviewed major hazards at the Station which included the location, storage, quantity, and potential exposure conditions. No deviations pertaining to bulk storage of dangerous goods were identified as a result of these assessments. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 6.8.8 specifies requirements for storage of radioactive materials. All sub-clauses are unchanged in N293-12. The Pickering NGS FHAs conducted an evaluation of the radioactive material storage rooms. These evaluations reviewed the construction, ventilation and drainage provided for these rooms. Areas for improvement were	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	identified and dispositioned to ensure adequate controls are provided for these rooms to satisfy the intent of this clause. All recommendations of the Fire Protection Assessment reports have been implemented or dispositioned (per NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-06731 R000 [B.2-28]). Therefore, the intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 6.8.9 specifies requirements for the control of ignition sources. All sub-clauses are unchanged in N293-12. Existing ignition sources were identified for the Pickering NGS FHAs ([B.2-23], [B.2-48]) and found to meet fire protection goals. Process controls for operations that present an ignition source hazard were confirmed to be established and used at the Station (see N-PROC-RA-0057 R008, "Control of Ignition Sources and Hot Work Activities" [B.2-64]). Adequate protection against lightning is provided for all structures as per Ontario Hydro Grounding standards and practices. New structures would be assessed against NFPA 780 as called for in CSA N293-07 and -12. External fire hazards (e.g., Standby Generator Fuel Storage, Power Transformer, site vehicle and site vegetation fires) were also assessed and documented in the FSSA and FHA reports. These external hazard assessments determined that the nuclear safety criteria specified in N293 would not be impacted. Therefore, the intent of this sub-clause is met and there is no PSR2 gap.	
7 Design and Installation Requirements for Fire Protection Systems 7.1 General 7.2 Fire Alarm Systems 7.3 Fire Suppression 7.4 Seismic Qualification	Clause 7 of N293-12 specifies requirements for design and installation of fire protection systems. None of the Section 7 sub-clauses were assessed in the 2015 Pickering A and B N293-07 reviews ([B.2-21], [B.2-47]). With respect to the individual sub-clauses: • Clause 7.1 specifies requirements for qualification of fire protection devices and equipment. All sub-clauses are unchanged in N293-12. The Pickering NGS CCRs ([B.2-17], [B.2-43]) and FHAs ([B.2-23], [B.2-48]) reviewed the fire protection systems for appropriateness, effectiveness and reliability. Part of this assessment involved the review of system components from design documentation to confirm they were from accredited organizations. No deviations or findings were noted in these assessments. Therefore, the intent of this clause is met and there is no PSR2 gap.	Gap **PSR2 CSA N293-12 Gap #1** - Clause 7.2.1.10.1 on Fire Alarm System Control **PSR2 CSA N293-12 Gap #2** - Clause 7.2.1.13 on Fire Endurance

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	• Clause 7.2 specifies requirements for fire alarm systems: o Sub-clause 7.2.1 specifies general fire alarm system concepts, including requirements relating to use of early warning technology, voice communication systems, staged operation, power supplies for fire alarm and voice communication systems, display and control centres, and extinguishing-agent-releasing systems. A number of the sub-clauses have changed in N293-12, but all changes are editorial except for assignment of the very early warning fire detection installation requirements (from N293-07 Clause 7.2.1.1) to a separate N293-12 sub-clause 7.2.1.2. Pickering NGS Fire Protection System Design Manuals NA44-DM-71400.2-00001 R001, "Fire Protection – Smoke Detection" [B.2-65], NA44-DM-71400-00002 R000, "Fire Protection Systems (Water)" [B.2-66], NK30-DM-67140-00001 R011, "Fire Detection - Fire Protection System" [B.2-67] and NK30-DM-71400-00001 R006, "Fire Protection System" [B.2-68] state that the fire alarm systems are designed and commissioned to the requirements of CAN/ULC-S524 and S537 as required by sub-clause 7.2.1.1. As per Safety Report NA44-SR-01320-00001 R015 [B.2-69], Pickering A is equipped with a public address system for general communication of messages and emergency signals to station personnel throughout the plant. Tone alarm signals can be initiated over the public address system by the unit operators in the MCRs. An emergency tone takes priority over all other forms of paging with a fire alarm tone taking second priority. Similar provisions apply to Pickering B. Two-way radios are provided as the main means of communication between emergency responders and the shift supervisor with telephone backup in the event of inadequate radio reception. The fire alarm systems at the Station consist of alarm devices that alarm to a control panel in the MCR, a Public Address system to provide notification, and a dedicated ERT to investigate alarms and respond as required. The automatic fire suppression systems in use at Pickering NGS are equipped with hardware listed for use as an extinguishing-agent releasing system. Data Gathering Panels and the Display Annunciation Stations (DAS) are provided un-interruptible Class II	of Electrical Conductors **PSR2 CSA N293-12 Gap #3** - Clause 7.3.2.2 (d) on Fire Pumps

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	120Vac regulated electrical power (as per NA44-DM-71400.2-00001 R001 [B.2-65] and NK30-DM-67140-00001 R011 [B.2-67]). Clause 7.2.1.10.1 states: "A display and control centre shall be located in the MCR… capable of providing detailed information on the location and nature of the signal. In addition, the panel operator shall be able to control the fire alarm system without having to leave his or her station." Per Section 3.2.3 of Design Manual NK30-DM-67140-00001 R011 [B.2-67], DAS 058-67140-TVM2 in the EOC (254' Service Wing Extension) provides the ability to control the fire alarm system. DAS 058-67140-TVM1 installed in the Pickering 058 MCR is capable of providing fire alarm system annunciation. While TVM1 does not have control capability, it "can be configured to provide the control capability by changing the software key at the back of TVM1" [B.2-67]. Pickering 014 DAS 014-67140-WS2342 in the EOC is capable of providing annunciation only, and there is no DAS in the Pickering 014 MCR (although there is limited annunciation). Therefore, this is identified as a PSR2 gap (**PSR2 CSA N293-12 Gap #1**). Clause 7.2.1.13 states: "Electrical conductors that are installed in service spaces containing other combustible materials and that are used in connection with fire alarm systems and emergency equipment, including fire alarm cables… shall be capable of performing their intended functions for not less than 1 hour after the start of a fire." Modifications to the Fire Protection System meet the requirements of CAN/ULC-S524 which mandates a 1 hour fire rating as described in Section 2.5 of NA44-DM-71400.2-00001 R001 [B.2-65], Section A.2 of NA44-DM-71400-00002 R000 [B.2-66], and Section 2 of NK30-DM-71400-00001 R006 [B.2-68]. This is achieved by the use of Edwards System Technology (EST) that connects the fire alarm control panels via a data communication link with dual redundant circuit wiring paths. However, existing Pyrotronics fire alarm control panels (not replaced in fire protection upgrade projects) are not similarly connected and, hence, may be susceptible to loss of alarm signal due to spot burning of a cable. While measures such as lack of combustible material in service spaces, combustible transient material control practices, and inherent protection afforded by Pickering NGS cable routing practices used in the	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	Fire Protection systems mitigate the lack of such a feature, it could not be confirmed based on existing documentation that all essential fire alarm cables are capable of performing their intended functions for not less than 1 hour after the start of a fire to meet the requirement of N293-12 sub-clause 7.2.1.13. Therefore, this is identified as a PSR2 gap (**PSR2 CSA N293-12 Gap #2**). o Sub-clause 7.2.2 specifies requirements for input devices, including manual pull stations, early warning fire detection technology and alternate fire detection methods. Sub-clause 7.2.2.4 has changed in N293-12 to replace the acronym "FHA" with "FPA", which is editorial. Manual pull stations are not provided in areas other than the Service Wing Extension of the station. Instead, the station emergency telephone system is used. This has been assessed and accepted as identified in Third Party Review reports NA44-CORR-00531-05151 R000 [B.2-70] and NK30-REP-71400-00011 R000 [B.2-71], as described in the CCRs ([B.2-17], [B.2-43]). The Pickering NGS FSSAs and FHAs demonstrate, with technical justification, the acceptability of fire detection methods installed in the Station to achieve safe shutdown goals. Smoke detectors are provided in the MCR that transmit alarm signals to the Very Early Smoke Detection (VESDA) panels as per NA44-DM-71400.2-00001 R001 [B.2-65] and NK30-DM-67140-00001 R011 [B.2-67]. Actions to take if the system is out of service are identified in the operating documentation as per standard content of Operating Manuals. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 7.2.3 specifies requirements for output devices, including audible and/or visual fire detection and alarm signal devices and telephone handsets. All sub-clauses are unchanged in N293-12. The Pickering NGS CCRs, FHAs and FSSAs demonstrate acceptability of fire detection methods installed in the Station to achieve safe shutdown goals. Design Manuals on Communications, e.g., NK30-DM-60200-00001 R001, "Communications" [B.2-72], demonstrate compliance with this Clause. Therefore, the intent of this sub-clause is met and there is no PSR2 gap.	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	• Clause 7.3 provides requirements for fire suppression. ○ Sub-clause 7.3.1 specifies general fire suppression requirements, including requirements relating to selection of a fire suppression system (via review of the design basis fire, performance levels, reliability, and potential damage resulting from fire suppression agents), automatic sprinkler systems, and design, installation, and registry of fire suppression systems in accordance with pressure-retaining component requirements. Some sub-clauses were changed in N293-12 involving minor editorial revisions (e.g., replacement of "FHA" with "FPA"). Design basis fires have been analyzed as part of the FSSAs and FHAs ([B.2-23], [B.2-48] and [B.2-24], [B.2-49], respectively) with and without suppression credited. The FHAs also reviewed the appropriateness and effectiveness of fire suppression systems. Performance and reliability requirements have been taken into consideration for all fire suppression systems (see NA44-DM-71400-00002 R000 [B.2-66] and NK30-DM-71400-00001 R006 [B.2-68]). The potential damage resulting from the fire suppression agent was analyzed in the FSSAs and documented under the heading "Fire Protection System Operation". As per Design Manuals NA44-DM-71400-00002 [B.2-66] and NK30-DM-71400-00001 [B.2-68], fire suppression systems are provided at Pickering NGS. More generally, the CCRs, FHAs and FSSAs demonstrate acceptability of fire suppression methods installed in the Station to achieve safe shutdown goals. Pressure retaining components of the fire suppression systems have been designed and installed per ASME B31.1 "Power Piping Code" (or ASME B31.3 "Process Piping Code"), CSA B51 "Boiler, Pressure Vessel and Pressure Piping Code" and N285.0 "General Requirements for Pressure Retaining Components in CANDU Nuclear Power Plants" (per NA44-DM-71400-00002 R000 [B.2-66] and NK30-DM-71400-00001 R006 [B.2-68]). Therefore, the intent of this sub-clause is met and there is no PSR2 gap. ○ Sub-clause 7.3.2 specifies requirements for the fire protection water supply, including sources of water, fire protection water supply volume, the ability to draft water from the supply source with fire trucks, and the use of diesel fire pumps in accordance with	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	NFPA 20. Some sub-clauses have changed in N293-12 involving minor editorial revisions (e.g., replacement of "FHA" with "FPA"). Sub-clause 7.3.2.1.2 has changed in N293-12 to clarify that 88.9 mm (3.5 inch) and larger hoses need only be included in the hose demand when required by the Station's pre-fire plans. The sources of water used in the fire protection systems at Pickering NGS meet the requirements of this clause. The primary supply of water is Lake Ontario. As per NK30-DM-71400-00001 R006 [B.2-68], at Pickering B "the water supply is sized to accommodate the most demanding calculated design flow". As per NA44-DM-71400-00002 R000 [B.2-66], Pickering A meets the requirements of N293-95 whose equivalent Clause 6.4.4 states: "the water supply system shall be designed to supply the most demanding fire-extinguishing system plus a supply for hose streams". Both Pickering Units 1,4 and Units 5-8 meet OPG Engineering Standard N-STM-78220-10000 R001, "Fire Protection for Turbine Generator Area" [B.2-73] which requires a hose stream allowance of 750 USgpm. Pickering Units 1,4 also meet N-STM-67140-10000 R001, "Fire Protection for Main Control Room, Control Equipment Room and Cable Spreading Areas" [B.2-74]. Even if the hose stream demand were as in N293-95 (500 USgpm), instead of as in N293-12 (750 USgpm), this would not be considered to impact the capability of the fire protection systems to the extent that nuclear safety objectives are jeopardised. The Pickering station has the ability to draft water from the forebay. The capability of fire response actions has been assessed in the FHAs and FSSAs and shown to be adequate to meet nuclear safety objectives. However, Clause 7.3.2.2 (d) of CSA N293-12 states that: "At a minimum, the fire protection water pumping system shall consist of at least one diesel-engine-driven fire pump and one electric-motor-driven fire pump set, with each pump set being capable of providing, the flow rate and pressure specified in Item (a)". This Clause is met at Pickering Units 1,4 with the provision of diesel-driven firewater pumps, backed up by supplies from the High Pressure Service Water (HPSW) system (as noted in the Pickering A Safety Report NA44-SR-01320-00001 R015, Section 11.5.1.1). It is not met	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	at Pickering Units 5-8, where the Fire Protection System comprises the HPSW supplies from the four B-side units. As a result, Pickering Units 5-8 does not comply with Clause 7.3.2.2 (d) of CSA N293-12 and this has been identified as a PSR2 gap (**PSR2 CSA N293-12 Gap #3**). ○ Sub-clause 7.3.3 specifies requirements for automatic and manual water-based fire suppression systems, including automatic sprinkler system design and installation (in accordance with NFPA 13 and NFPA 15), water hose stream allowance, measures for diking and/or drainage and transformer fires. No sub-clauses have changed in N293-12 except sub-clause 7.3.3.5, which has added a new requirement for passive heat barriers to protect cables. Modifications to the Fire Protection System have been made to meet the requirements of NFPA 13 and NFPA 15, per Design Manuals NA44-DM-71400-00002 R000 [B.2-66] and NK30-DM-71400-00001 R006 [B.2-68]. Water hose stream allowance has been added to sprinkler system demand as per Design Manuals NA44-DM-71400-00002 R000 [B.2-66] and NK30-DM-71400-00001 R006 [B.2-68]. The new requirement for passive heat barriers to protect cables at Pickering NGS could not be confirmed to be fully met. However, this does not translate into a measurable reduction in the plant's fire suppression capability or nuclear safety margins, since all cables requiring heat protection were identified in the FSSA and provided with heat shields. Measures for diking and/or drainage have been provided as required and assessed in the CCRs, FHAs and FSSAs. Nuclear safety objectives were demonstrated to be met. As discussed earlier, the FSSAs and FHAs analyzed potential transformer fires and determined that fire suppression is sufficient such that there is no impact on fire safe shutdown capabilities. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. ○ Sub-clause 7.3.4 specifies requirements for special extinguishing systems. One sub-clause has changed in N293-12 to use the acronym "FSA" instead of "FHA", which is editorial. Special extinguishing systems are in use at Pickering NGS and have been	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	determined in the FHAs ([B.2-23], [B.2-48]) to be suitable for the hazards they are protecting against. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 7.3.5 specifies requirements for portable extinguishers. The clause has not changed in N293-12. Portable fire extinguishers are provided at Pickering NGS for use by plant staff prior to ERT response. Adequacy of coverage has been assessed in the CCRs ([B.2-17], [B.2-43]). All recommendations of the FHAs related to portable fire extinguishers have been implemented or dispositioned (per NA44-CORR-00531-07475 R000 [B.2-53], NK30-CORR-00531-06731 R000 [B.2-28]). Therefore, the intent of this clause is met and there is no PSR2 gap. o Sub-clause 7.3.6 specifies requirements for fire hydrants. The clause has not changed in N293-12. Fire hydrants are provided in outdoor areas. Pickering NGS adequacy of coverage has been assessed in the CCRs ([B.2-17], [B.2-43]) and found to be compliant with applicable codes. Fire hydrants at Pickering NGS are clearly enough marked that no deviations have been found in the CCRs, or any adverse impact noted by the FHAs and FSSAs on meeting safe shutdown requirements. Although the specified maximum spacing of 250 feet (per Sub-clause 7.3.6.2) is not met, the provided 300 foot spacing at Pickering A and B (per NA44-DM-71400-00002 R000 [B.2-66] and NK30-DM-71400-00001 R006 [B.2-68]) does not translate into a measurable reduction in the plant's fire suppression capability or nuclear safety margins. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 7.3.7 specifies requirements for standpipes. The clause has not changed in N293-12. The Pickering fire protection Design Manuals (NA44-DM-71400.2-00001 R001 [B.2-65], NA44-DM-71400-00002 R000 [B.2-66], NK30-DM-67140-00001 R011 [B.2-67] and NK30-DM-71400-00001 R006 [B.2-68]) state that standpipes in the station meet the requirements of NFPA 14. At Pickering A, a 750 USgpm hose stream allowance is added to the Turbine-Generator sprinkler system demand. At Pickering B, NK30-DM-71400-00001 R006 [B.2-68] states "each standpipe shall be capable of delivering a minimum of 84 USgpm at 45 psi from its most remote hose connection". Standpipe systems inside	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	containment are not provided. Although some details of sub-clause 7.3.7 are not met, sufficient fire protection capability has been provided to be able to demonstrate by means of the FHAs and the FSSAs that safe shutdown capability is not impacted and nuclear safety objectives are met. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. o Sub-clause 7.3.8 specifies requirements for manual firefighting. A number of sub-clauses have changed in N293-12 to replace the acronym "FHA" by "FPA", which is editorial. Manual firefighting provisions are in place at the Pickering NGS per N-PROG-RA-0012 R011, "Fire Protection" [B.2-9] and N-STD-RA-0039 R004, "Requirements for Fire Response Capability" [B.2-75]. Therefore, the intent of this sub-clause is met and there is no PSR2 gap. • Clause 7.4 provides requirements for seismic qualification of fire protection systems. This clause has changed in N293-12 to further clarify the seismic design requirements. Sub-clauses 7.4.1, 7.4.2 and 7.4.3 specify general seismic qualification requirements, including the use of seismic categories A and B. The seismic qualification requirements for the Pickering NGS fire protection systems are provided in Design Manuals NA44-DM-71400-00002 R000 [B.2-66] and NK30-DM-71400-00001 R006 [B.2-68]. For Pickering Units 1,4 this includes qualification of the manual valves and piping in the Unit 4 Control Equipment Room (CER), Units 1/2 and 3/4 Auxiliary CERs, as well as the sprinkler piping above the Auxiliary Boiler Feed Pump at floor elevations 254' and 274' in the Turbine Generator Area, to Seismic Category "A". For Pickering Units 5-8 this includes seismic qualification of the Emergency Power and Water Supply Building Air Foam System and the High Pressure Emergency Coolant Pump House Standpipe System. Further, the FHAs ([B.2-23], [B.2-48]) confirm that the consequences of a Design Basis Earthquake are not outside those of the fire scenarios addressed in the FSSAs ([B.2-24], [B.2-49]) and FHAs. Thus, the impact of seismic events on fire protection systems is considered at Pickering NGS and it is confirmed that nuclear safety objectives are met. The safe operation of the Pickering reactors following seismic events has been extensively assessed and mitigating systems and components that are required to function have been identified, along with the degree of their required functionality, i.e., whether Category A or	

CSA N293-12 Clause	PSR2 Review	Compliant or Gap
	Category B. This includes fire protection systems to the extent required. Based on the above, Pickering NGS complies with the intent of Clause 7.4 which is to ensure reactor safety following seismic events, and there is no PSR2 gap.	

Based on the information provided in Section B.2.2 above, there are three PSR2 CSA N293-12 gaps for Pickering NGS compliance with Clauses 7.2.1.10.1, 7.2.1.13 and 7.3.2.2 (d) of CSA N293-12.

B.2.3 Compliance Summary for Pickering PSR2

There are three PSR2 gaps for CSA N293-12 [B.2-1] which relate to Safety Factor 1 (Plant Design):

1. Clause 7.2.1.10.1 of CSA N293-12 states: "A display and control centre shall be located in the MCR [Main Control Room]… capable of providing detailed information on the location and nature of the signal. In addition, the panel operator shall be able to control the fire alarm system without having to leave his or her station." Pickering 014 Display Annunciation Station 014-67140-WS2342 in the Emergency Operating Centre is capable of providing annunciation only, and there is no Display Annunciation Station in the Pickering 014 MCR (although there is limited annunciation). Therefore, this has been identified as a PSR2 gap.

2. Clause 7.2.1.13 of CSA N293-12 states: "Electrical conductors that are installed in service spaces containing other combustible materials and that are used in connection with fire alarm systems and emergency equipment, including fire alarm cables… shall be capable of performing their intended functions for not less than 1 hour after the start of a fire." Modifications to the Fire Protection System meet the requirements of CAN/ULC-S524 which mandates a 1 hour fire rating as described in Section 2.5 of NA44-DM-71400.2-00001 R001, Section A.2 of NA44-DM-71400-00002 R000 and Section 2 of NK30-DM-71400-00001 R006. This is achieved by the use of Edwards System Technology (EST) that connects the fire alarm control panels via a data communication link with dual redundant circuit wiring paths. However, existing Pyrotronics fire alarm control panels are not similarly connected and, hence, may be susceptible to loss of alarm signal due to spot burning of a cable. While measures such as lack of combustible material in service spaces, combustible transient material control practices, and inherent protection afforded by Pickering NGS cable routing practices used in the Fire Protection systems mitigate the lack of such a feature, it could not be confirmed based on existing documentation that all essential fire alarm cables are capable of performing their intended functions for not less than 1 hour after the start of a fire to meet the requirement of N293-12 sub-clause 7.2.1.13. As a result, this has been identified as a PSR2 gap.

3. Clause 7.3.2.2 (d) of CSA N293-12 states: "At a minimum, the fire protection water pumping system shall consist of at least one diesel-engine-driven fire pump and one electric-motor-driven fire pump set, with each pump set being capable of providing, the flow rate and pressure specified in Item (a)". This Clause is met at Pickering Units 1,4 with the provision of diesel-driven firewater pumps, backed up by supplies from the High Pressure Service Water (HPSW) system (as noted in the Pickering A Safety Report NA44-SR-01320-00001 R015, Section 11.5.1.1). It is not met at Pickering Units 5-8, where the Fire Protection System is comprised of the HPSW supplies from the four units only. As a result, Pickering Units 5-8 does not comply with Clause 7.3.2.2 (d) of CSA N293-12 and this has been identified as a PSR2 gap.

B.3 CNSC REGDOC-2.4.1 (2014), "Deterministic Safety Analysis"

B.3.1 Background

The following paraphrased from the preface and introduction of CNSC REGDOC-2.4.1 [B.3-1] provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of REGDOC-2.4.1 is to help assure that during the construction, operation or decommissioning of a nuclear power plant, adequate safety analyses are completed by, or on behalf of, the applicant or licensee in accordance with the Nuclear Safety and Control Act and regulatory requirements.*
>
> *REGDOC-2.4.1 sets out requirements and guidance for the preparation and presentation of a safety analysis that demonstrates the safety of a nuclear facility. To the extent practicable, the document is technology-neutral and provides information on preparing and presenting deterministic safety analysis reports, including the selection of events to be analyzed, acceptance criteria, safety analysis methods, safety analysis documentation, and the review and update of safety analysis.*

CNSC REGDOC-2.4.1 is relevant to Safety Factors 5 (Deterministic Safety Analysis) and 7 (Hazard Analysis). Compliance with REGDOC-2.4.1 is currently a licensing requirement for Pickering NGS (per PROL 48.02/2018) as indicated in Appendix C.2 of the R04 Pickering Licence Conditions Handbook [B.3-2].

The current version of REGDOC-2.4.1 [B.3-1] is the first edition of the regulatory document and supersedes the following CNSC documents:

- RD-310, "Safety Analysis for Nuclear Power Plants" [B.3-3] (which replaced the draft CNSC document S-310 [B.3-4] and content from the AECB Draft Regulatory Guide C-006, Rev. 1 [B.3-5]);
- RD-308, "Deterministic Safety Analysis for Small Reactor Facilities" [B.3-6]; and
- GD-310, "Guidance on Safety Analysis for Nuclear Power Plants" [B.3-7].

Per the CNSC Document History for REGDOC-2.4.1 [B.3-8]:

> *The CNSC's Fukushima Task Force Report and the CNSC Integrated Action Plan on the lessons learned from the Fukushima Daiichi nuclear accident identified improvements to existing regulatory documents to strengthen the regulatory framework. REGDOC-2.4.1 includes targeted amendments to existing requirements that are specified in regulatory documents RD-310, "Safety Analysis for Nuclear Power Plants", and RD-308, "Deterministic Safety Analysis for Small Reactor Facilities", to address the lessons learned from the Fukushima event.*

REGDOC-2.4.1 also includes content from GD-310, which already included changes driven by the lessons from the Fukushima accident. As a result, the existing content has been integrated into REGDOC-2.4.1. The changes between RD-310 and REGDOC-2.4.1 are discussed further in the Sections below.

The results of PSR1 REGDOC-2.4.1 (and its predecessor) reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.3.2. As identified in Reference [B.3-9], the Pickering PSR2 review of CNSC REGDOC-2.4.1 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.
- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.3.2 Compliance Assessment for Pickering PSR2

B.3.2.1 Application of PSR1 Reviews

The versions of REGDOC-2.4.1 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

A review against Draft S-310 was performed as part of the Pickering B ISR, as documented in OPG Report NK30-REP-03680-00005 R000 [B.3-10]. Compliance with S-310 was demonstrated on the basis that it allows use of pre-2004 dose limits, and that "direct compliance with the modern requirements could likely be achieved with more realistic analysis" [B.3-10]. The report concludes:

> *It is judged that there are not any issues relating to S-310 in terms of radiological consequences that would be significant impediments to life extension.*

The same report also documents a review of C-006 Rev. 1 [B.3-5] to confirm that all initiating events are adequately addressed in the Pickering B Safety Report, which concluded the following:

> *In terms of Initiating Events, it is concluded that all of the C-006 R1 events are adequately addressed as being bounded by events explicitly analyzed in the Safety Report or are addressed in supplementary reviews including the Pickering B risk assessment, or in the Pickering A C-006 review Initiating Event dispositions.*

There are therefore no PSR2 gaps arising from the Pickering B ISR review of S-310 [B.3-4] or C-006 [B.3-5].

<u>Pickering Units 1,4</u>

AECB Draft Regulatory Document C-006 Rev. 1 [B.3-5] was reviewed for Pickering A Return to Service, as documented in NA44-REP-03500-00001 R00 [B.3-11] and submitted to the CNSC in NA44-CORR-00531-00560 [B.3-12]. The report concluded the following:

> *No significant deficiencies were identified as a result of the review with respect to plant design and operation of the completeness and correctness of the existing Pickering A Safety analysis in relationship to applicable license requirements. …*

The report concluded that if the Pickering A safety analysis were redone using C006-Rev. 1 as a standard, acceptable results would be obtained [B.3-11].

As such, there are no Pickering PSR2 gaps arising from the Pickering A Return to Service review of C-006 Rev. 1.

Pickering NGS compliance against REGDOC-2.4.1, which was not assessed as part of the Pickering B ISR or Pickering A Return to Service, is discussed below.

Darlington NGS

The Darlington ISR was originally performed against RD-310 [B.3-3], comprising a clause-by-clause review documented in OPG Report NK38-REP-03680-10102 R000 [B.3-13]. The review concluded that: "OPG governance and Darlington Design Guides are compliant with RD-310 for the objectives, responsibility, documentation, review, update, and quality assurance for safety analysis" [B.3-13]. OPG governance applies across OPG's nuclear stations so this is also applicable to PSR2. Five gaps in the Darlington Design Guides were identified for events to be analyzed, acceptance criteria, methods and assumptions. An additional five gaps were identified in response to the CNSC comments on the code review provided in NK38-REP-03680-10102-ADD-001 [B.3-14]. These ten gaps are described in the table below [B.3-15], [B.3-16].

Gap #	Associated RD-310 Clause	Darlington ISR Gap
0844	Clause 5.2.1 requires that a systematic process be used to identify events, event sequences, and event combinations that can potentially challenge the safety of control functions of the Nuclear Power Plant.	There are gaps in the analysis program for identifying initiating events, accounting for all power states and operational experience.
0845	Clause 5.2.3 requires that initiating events be classified into three categories: Abnormal Operational Occurrences (AOO), Design Basis Accidents (DBA), and Beyond Design Basis Accidents (BDBA).	Darlington NGS still uses the Class 1 to Class 5 classification scheme.

Gap #	Associated RD-310 Clause	Darlington ISR Gap
0846	Clause 5.3.2 requires that analysis for AOO demonstrate that radiological doses to members of the public do not exceed the established limits and that the derived acceptance criteria are met.	Documentation issues for some AOO analyses.
0847	Clauses 5.3.3 requires that Analysis for BDBA shall be performed as part of the safety assessment.	Design Guides do not require analysis of BDBA.
0848	Clause 5.4.4 provides requirements for BDBA analysis assumptions.	BDBA analysis has not been systematically performed.
1735	Clause 5.3.4 and 5.4.2 require qualitative acceptance criteria to be established for each AOO and to demonstrate that the criteria are met through identification of quantitative derived acceptance criteria prior to performing the analysis. The analysis method is to identify the applicable acceptance criteria, safety requirements and limits.	This work is in progress via pilot AOO analyses and therefore cannot be classified as compliant.
1736	Clauses 5.3.4 and 5.4.3 require the results of AOO and DBA safety analyses to meet appropriate derived acceptance criteria with margins sufficient to accommodate uncertainties associated with the analysis and significant uncertainties in analysis data, including those associated with nuclear power plant performance, operational measurements, and modelling parameters to be identified.	The claim that 'margins to accommodate uncertainty are included in derived acceptance criteria and in the use of bounding operating parameters' requires demonstration. It is expected that the industry safety analysis improvement (SAI) working group will develop a plan and implement it to demonstrate the Limit of Operating Envelope (LOE) conservatism and adequacy for RD-310 compliance, however, since the work is in progress this represents a gap to these clauses.
1746	Clause 5.4.1 requires the analysis to provide the appropriate level of confidence in demonstrating conformity with the acceptance criteria.	Per the CNSC comment: "Whether the current LOE methodology accommodates modelling uncertainties requires demonstration."
1747	Clause 5.4.2 requires the analysis method to account for uncertainties in the analysis data and models.	CNSC staff conclude that no modelling uncertainty is considered.
1748	Clause 5.4.6 requires the safety analysis to build in a degree of conservatism to off-set any uncertainties associated with both Nuclear Power Plant (NPP) initial and boundary conditions and modeling of nuclear power plant performance in the analyzed event.	CNSC staff expects formal documentation on where conservatisms are built in and where they are used to off-set uncertainties.

These gaps, which are specific to RD-310 implementation, also relate to Governance, Programs, Procedures and Practices that apply across OPG's Nuclear operations and are therefore also applicable to PSR2. These gaps are further discussed below with respect to the ongoing work toward compliance with RD-310 and subsequently REGDOC-2.4.1 post-PSR1.

The gaps outlined above were assigned to 5 Darlington ISR Issues (D027, D028, D030, D399 and D400) in the Final ISR Report and Addenda [B.3-15], [B.3-16]. The resolution of all gaps associated with RD-310 was tracked through CNSC Action Item 2010-OPG-05 "Completion of RD-310 compliance activities." Action Item 2010-OPG-05 included implementation of RD-310 by 2021 Q4, as described in The Second Addendum to the Final ISR Report, NK38-REP-03680-10102-ADD-002 [B.3-16]:

> *A detailed plan for OPG implementation of RD-310 was submitted in December, 2012. It includes a timeline for OPG implementation of RD-310 in safety analysis and its incorporation into the upgrade of the Darlington Safety Report. The timeline made a commitment to have the Safety Report comprehensively comply with RD-310 by Q4 2021, with a staged implementation of updated accident analyses and appendices.*

According to the Final ISR Report, the RD-310 implementation process "is managed under the Reactor Safety Program N-PROG-MP-0014 and is formally communicated to the CNSC via this program on a semi-annual basis" [B.3-17].

With the release of REGDOC-2.4.1, the five issues identified above were regrouped into two issues specific to REGDOC-2.4.1 compliance in Appendix A, Table 4, of the latest revision of the Darlington IIP [B.3-18]:

1. IIP-OI-035 (D027): "A systematic analysis of BDBA and Severe Accidents is required and Severe Accident Management Guidelines must be fully implemented".

2. IIP-OI-043 (D028, D030, D399 and D400): "Comply with the new requirements of CNSC REGDOC-2.4.1".

Under CNSC Action Item 2010-OPG-05, the RD-310 Compliance activities to address the gaps found during the Darlington ISR were to be addressed through OPG's Safety Analysis Improvement (SAI) initiative. With the release of REGDOC-2.4.1, the SAI plans were revised to reflect the graded approach permitted by REGDOC-2.4.1. According to N-CORR-00531-07338 [B.3-19], the CNSC staff agreed in principle with the new direction of OPG's SAI efforts. Action Item (AI) 2010-OPG-05 was closed, while AI 2014-OPG-5461 was opened to track compliance with REGDOC-2.4.1 with a completion date of 2024 [B.3-19].

Closure of AI 2014-OPG-5461 was requested [B.3-20] and granted [B.3-21] with the development and acceptance of the REGDOC-2.4.1 Implementation Plan [B.3-22], which superseded the RD-310 Implementation Plan [B.3-23]. Action Request #28189400 was opened to track the implementation of REGDOC-2.4.1 to meet Pickering PROL Licence Condition 5.1. This work is still in progress and therefore is identified as **PSR2 REGDOC-2.4.1 Gap #1**.

B.3.2.2 Application of Post-PSR1 Reviews

Pickering A and B RD-310 Assessments

With the publication of RD-310, assessments of each of the Pickering Units 1,4 and Units 5-8 Safety Report Appendices against the requirements of RD-310 were summarized in the Pickering A and Pickering B RD-310 Implementation Plan [B.3-23]. The gaps found were consistent with those identified in the Darlington ISR review with the addition of several gaps, summarized as follows:

1. For all Safety Report appendices, gaps were found with RD-310 Clause 5.2.2 which requires the list of events identified for the safety analysis to include operator errors and common-cause internally and externally initiated events. The clause also requires that the selected cut-off frequency is justified and excluded events documented.

2. For all Safety Report appendices, it was found that the safety analysis does not meet Clause 5.4.5 which requires that computer codes used in the safety analysis shall be developed, validated and used in accordance with a quality assurance program that meets the requirements of CSA N286.7-99.

3. For all Safety Report appendices, it was found that the safety analysis does not meet the requirements for documentation as required in Clause 5.5.

4. For all Safety Report appendices, it was found that the quality assurance program does not adequately address the validation of NPP and analytical models as required in Clause 5.7.

The RD-310 Implementation Plan was developed through the prioritization of the gaps requiring resolution along with regulatory considerations, OPG business drivers, and analyses already underway for purposes other than RD-310 compliance. The prioritization of the gaps to be addressed as part of the RD-310 Implementation Plan was based on the expected end of commercial operation date of Pickering A and B of 2020, with the focus of RD-310 compliance on continued demonstration of adequate safety margins in light of ongoing aging mechanisms [B.3-23]. The progress of the RD-310 Implementation Plan was tracked under Action Item 2010-OPG-05. As noted in OPG letter to the CNSC, N-CORR-00531-06076 [B.3-24]:

> *In contrast to the Darlington Implementation Plan, limited upgrades are proposed in the Pickering A and B Plan, which has been developed with consideration for demonstration of continued safe operation while accounting for the limited remaining operating life of the Pickering Units.*

As documented in N-CORR-00531-06256 [B.3-25], the CNSC accepted the RD-310 Implementation Plan, concluding that the RD-310 gaps in the Pickering A and B Safety Report analyses were adequately identified and documented, and that the Implementation Plan was based on a well-documented process and the selected scope for RD-310 compliant analyses was justified [B.3-25]. While the selection of scope was accepted, this was based on a projected end of commercial operation date of 2020. The same prioritization criteria used to select the scope of the RD-310 implementation were carried forward into the REGDOC-2.4.1 Implementation Plan, described further below. As a result, Pickering NGS operation beyond 2020 results in a gap with respect to the basis used for identifying selected analysis updates to comply with REGDOC-2.4.1 for the PSR2 period. This gap is identified as **PSR2 REGDOC-2.4.1 Gap #2**.

REGDOC-2.4.1 Implementation Plan

CNSC REGDOC-2.4.1 was published in 2014. As indicated in the REGDOC-2.4.1 Implementation Plan [B.3-22]:

> *REGDOC-2.4.1 is very similar to RD-310 and GD-310 in technical requirements and guidance.*

According to the OPG REGDOC-2.4.1 Gap Assessment [B.3-26]:

> *The most significant change between RD-310 and REGDOC-2.4.1, for OPG, is that REGDOC-2.4.1 permits a graded approach to updating existing analyses.*

Based on this graded approach, only the most significant gap for Pickering (the absence of a Common Mode Event Appendix) was identified for development to REGDOC-2.4.1 requirements [B.3-22]. Therefore, the gap assessment for REGDOC-2.4.1, which mapped the REGDOC-2.4.1 clauses to their corresponding clauses of RD-310 and assessed the differences, focused on the Darlington RD-310 gaps.

The Darlington REGDOC-2.4.1 gap assessment identified two additional gaps related to cliff-edge effects that are programmatically applicable to Pickering. As discussed above, the REGDOC-2.4.1 Implementation Plan needs to be reconsidered in the context of extended operation beyond 2020. Since REGDOC-2.4.1 requirements will be revisited as part of that review, there is no incremental gap for PSR2.

The Implementation Plan for REGDOC-2.4.1 at Pickering NGS is summarized in the PROL Amendment request [B.3-27]:

> *In alignment with current Pickering licensing requirements, and with the graded approach permitted by REGDOC-2.4.1 requirements, OPG will be upgrading the Pickering safety reports only to the extent that a new appendix will be included to address the development and analysis of common mode events in 2017. The analysis of common mode events represents the single largest gap in the Pickering Safety Reports with respect to REGDOC-2.4.1.*
>
> *Beyond 2017, Pickering NGS will be maintaining a safety analysis program compliant with REGDOC-2.4.1 requirements. OPG will perform to the extent practicable, any new Pickering specific safety analyses in accordance with REGDOC-2.4.1 requirements. OPG will continue to utilize the existing OPG safety report update process to comply with the regulatory requirements or updating safety reports periodically.*

The graded approach to evaluating and addressing the gaps with REGDOC-2.4.1 compliance is recognized in the Licence Conditions Handbook, which identifies the following criteria for implementation of REGDOC-2.4.1 [B.3-2]:

- *Assessment of the current safety analysis practices against REGDOC 2.4.1 to identify gaps;*
- *Prioritization of the identified gaps using formal methods;*
- *Justification of non-conformances (e.g., full compliance with REGDOC 2.4.1 is not practicable or does not provide a demonstrable safety benefit); and*
- *Development and execution of corrective action plans to address the important gaps.*

As identified in OPG letter N-CORR-00531-06865 R000, "Resolution of Large Break LOCA (LBLOCA) Safety Margin Issues" [B.3-28], OPG has initiated a project to update the LBLOCA analyses using the LOE methodology for the OPG Nuclear fleet as part of the REGDOC-2.4.1 compliance initiative. The status of this project is discussed in N-CORR-00531-18022 R000, "Resolution of Large Break LOCA Safety Analysis Margin Issues" [B.3-29].

B.3.3 Compliance Summary for Pickering PSR2

There are two PSR2 CNSC REGDOC-2.4.1 (2014) gaps which relate to Safety Factor 5 (Deterministic Safety Analysis):

1. The REGDOC-2.4.1 Implementation Plan and associated gap assessments capture all gaps related to REGDOC-2.4.1 and incorporate a systematic selection of the scope of work to address the most pertinent gaps in accordance with the graded approach to upgrading existing analyses. REGDOC-2.4.1 compliant analysis activities and progress related to REGDOC-2.4.1 implementation in the Pickering Licence Conditions Handbook are tracked according to the CNSC Compliance Verification Criteria. Since the implementation is in progress, this has been identified as a PSR2 gap for Pickering NGS REGDOC-2.4.1 compliance.

2. As described in the REGDOC-2.4.1 Implementation Plan: "Limited upgrades are proposed in the Pickering A and B Plan, which has been developed with consideration for demonstration of continued safe operation while accounting for the limited remaining operating life of the Pickering Units". The REGDOC-2.4.1 Implementation Plan for Pickering did not consider operation past 2020 and therefore the need for review and update of the Implementation Plan in the context of operation of Pickering NGS beyond 2020 is identified as a PSR2 gap. This will be informed by the timeline of the Darlington REGDOC-2.4.1 Implementation Plan, and the limited additional years of Pickering NGS operation.

B.4 CNSC REGDOC-2.4.2 (2014), "Probabilistic Safety Assessment (PSA) for Nuclear Power Plants"

B.4.1 Background

The following, paraphrased from the preface and introduction of CNSC REGDOC-2.4.2 [B.4-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The objectives of a probabilistic safety assessment (PSA) include provision of a systematic analysis to give confidence that the design will align with the fundamental safety objective. REGDOC-2.4.2 assures that the licensee conducts a PSA in accordance with defined requirements when incorporated into a licence to construct or operate a nuclear power plant [NPP].*
>
> *REGDOC-2.4.2 sets out the requirements for the PSA for a licence to construct or operate an NPP, when required by the applicable licence.*

CNSC REGDOC-2.4.2 is relevant to Safety Factors 6 (Probabilistic Safety Assessment) and 7 (Hazard Analysis).

Compliance with REGDOC-2.4.2 is currently a licence requirement for Pickering NGS (per PROL 48.02/2018) as indicated in Appendix C.2 of the R04 Pickering Licence Conditions Handbook [B.4-2]. When OPG requested that the CNSC amend the Operating Licence to replace S-294 with REGDOC-2.4.2, a transition plan was also submitted. The transition plan is discussed in paragraph 15 of Reference [B.4-3].

REGDOC-2.4.2 supersedes S-294, "Probabilistic Safety Assessment (PSA) for Nuclear Power Plants" [B.4-4]. As outlined in Reference [B.4-5]:

> *The CNSC's Fukushima Task Force Report and the CNSC Integrated Action Plan on the lessons learned from the Fukushima Daiichi nuclear accident, identified improvements to existing regulatory documents to strengthen the regulatory framework. REGDOC-2.4.2 includes targeted amendments to existing requirements that are specified in regulatory document S-294, to address the lessons learned from the Fukushima event… As a result of additional feedback from stakeholders, guidance has been included to clarify the intent of certain requirements.*

The results of PSR1 REGDOC-2.4.2 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.4.2. As identified in Reference [B.4-6], the Pickering PSR2 review of CNSC REGDOC-2.4.2 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.

- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.4.2 Compliance Assessment for Pickering PSR2

B.4.2.1 Application of PSR1 Reviews

The versions of REGDOC-2.4.2 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

The Pickering B ISR included a Safety Analysis Review report [B.4-7] which addressed Probabilistic Risk Assessment (also referred to as PSA) and included a clause-by-clause review of S-294 compliance. A discrepancy was identified as follows:

> *CNSC regulatory document S-294 identifies external events to be included in the PRA (e.g., seismic, flooding, and tornados). The PBRA [8] does not currently include these events, or fire, as an initiating event. However, S-294 allows assessment of events by other methods. OPG has addressed these events via hazard assessments and design (i.e., fire and seismic).*

Subsequently OPG has completed PSAs for Pickering Units 5-8 [B.4-8] and for Pickering Units 1,4 [B.4-9], which were prepared in accordance with CNSC Regulatory Standard S-294 and updated to include the enhancements mandated in the Fukushima Action Plan. The PSAs include detailed Level 1 at-power assessments for seismic events, internal floods, and high winds (including tornados), bounding Level 2 at-power and Level 1/2 outage assessments for those hazards, and screening assessment for external flooding events.

The foregoing is further recognized in Section 5.1 of the R04 Pickering Licence Conditions Handbook [B.4-2] which states:

> *OPG submitted a S-294 compliant Pickering B PSA in 2012, and completed the compliant Pickering A PSA in 2014. In addition, in preparation for the hold point hearing in 2014, OPG incorporated the credits due to the enhancements required under the Fukushima Action Plan in the PSAs for both Pickering A and B.*

There are therefore no PSR1 gaps that are applicable in PSR2. The status of implementation of REGDOC-2.4.2 is discussed further in Section B.4.2.2 below.

---

[8] Pickering B Risk Assessment

Pickering Units 1,4

REGDOC-2.4.2 did not exist when the Pickering A RTS assessments were performed. REGDOC-2.4.2 and S-294 were not within the scope of PSR1 as it related to Pickering Units 1,4. However, as discussed above, compliance with S-294 is recognized in Section 5.1 of the R04 Pickering Licence Conditions Handbook [B.4-2]. The status of implementation of REGDOC-2.4.2 is discussed further in Section B.4.2.2 below.

Darlington NGS

The Darlington ISR performed an assessment of the Safety Analysis Safety Factor, which at that time included PSA together with Deterministic Safety Analysis and Hazard Analysis. A detailed clause-by-clause review of S-294 [B.4-10] concluded that:

> *OPG Nuclear governance and the practices at Darlington NGS do not currently meet all of the requirements of S-294. The key issues are summarized as follows:*
>
> 1. *The overall OPG PRA Standard and specific instructions for Level 1 At-Power Internal Events PRA are compliant with the requirements of S-294 and have been accepted by the CNSC. While the intent of specific instructions for other assessments (Level 2; Outage; External Events) should be consistent, a gap in compliance exists until such time that the methodology documents for these other assessments are formally issued.*
>
> 2. *The existing draft DARA [Darlington Risk Assessment] models comply with most but not all of the requirements of the governance documents. This has been recognized, and will be rectified by completion of the updated DARA for submission to the CNSC in December 2010. When the update project is complete, the DARA (Level 1 and 2, internal events, at-power and outage) will comply with the requirements of S-294; until then, the existing draft DARA represents a gap in compliance of station practice with the requirements of S-294.*
>
> 3. *Projects for Darlington fire, seismic, and flooding risk assessments are underway but no formal models or results have been issued to date. Until these projects are complete, this represents a gap in compliance of station practice with the requirements of S-294.*

Based on the S-294 code review [B.4-10], seven gaps were identified in the Safety Analysis Safety Factor report [B.4-11]. The conclusion in terms of PSA was that "Darlington has recently initiated an update of DARA to be compliant with the CNSC regulatory standard S-294". Since OPG has completed PSAs for Pickering Units 5-8 [B.4-8] and for Pickering Units 1,4 [B.4-9] in accordance with CNSC Regulatory Standard S-294, the PSR1 gaps from Darlington do not apply to Pickering and there is no PSR2 gap.

B.4.2.2 Application of Post PSR1 Reviews

A comparison of S-294 to REGDOC-2.4.2 has been performed by CANDU Owner's Group [B.4-12]. The assessment was a factor when a transition plan was developed to include

REGDOC-2.4.2 in the PROL as noted in the following discussion from Section 5.1 of the R04 Pickering Licence Conditions Handbook [B.4-2]:

> *REGDOC-2.4.2 Probabilistic Safety Assessment (PSA) for Nuclear Power Plants Implementation Strategy: OPG will update the Pickering A PSA and Pickering B PSA using a graded approach as permitted by REGDOC-2.4.2. The PSA elements created as part of S-294 will be updated and the updated requirements of REGDOC-2.4.2, such as Irradiated Fuel Bay (IFB) risk assessment, will be addressed.*
>
> *The next Pickering B PSA update will be completed in 2017, including detailed risk re-quantification, in accordance with S-294. Similarly, the next Pickering A PSA update will be completed in 2018, including detailed risk re-quantification, in accordance with S-294.*
>
> *All the Pickering A PSA and Pickering B PSA updates extended to 2020 will be solely focused on the additional updated requirements of REGDOC-2.4.2 going beyond S-294 requirements, including for example, IFB risk assessment, and which are risk contributors of less significance. The updated requirements of REGDOC-2.4.2 may be dealt with through alternative methods to PSA for which guidance is currently being developed by industry.*
>
> *OPG is required to inform the Commission by June 30, 2017 as to whether or not the Pickering units will end commercial operation by December 2020. Should a decision be made to continue to operate the Pickering units beyond 2020, CNSC and OPG staff will engage in further discussions in 2017 on what will be required for Pickering NGS PSA updates beyond 2020 ...*

The Licence Conditions Handbook identifies that following the Pickering 5-8 update in 2017 and the Pickering 1,4 update in 2018, subsequent PSAs will be focused on the additional updated requirements of REGDOC-2.4.2. Also, some of the additional REGDOC-2.4.2 requirements may be dealt with through alternative methods to PSA for which guidance is currently being developed by the industry. The REGDOC-2.4.2 Implementation Plan for Pickering that was agreed to with the CNSC did not consider operation past 2020 and therefore the need for review and update of the Implementation Plan in the context of operation of Pickering NGS beyond 2020 is identified as a gap. (**PSR2 REGDOC-2.4.2 Gap #1**).

B.4.3 Compliance Summary for Pickering PSR2

There is one PSR2 CNSC REGDOC-2.4.2 (2014) gap which relates to Safety Factor 6 (Probabilistic Safety Assessment):

1. The REGDOC-2.4.2 Pickering Implementation Plan agreed to with the CNSC did not consider operation beyond 2020 and therefore, the review and update of the Implementation Plan in the context of operation of Pickering NGS beyond 2020 is required. Therefore, this has been identified as a PSR2 gap.

B.5 CSA N287.1-14, "General Requirements for Concrete Containment Structures for Nuclear Power Plants"

B.5.1 Background

The following, paraphrased from the Preface of CSA N287.1-14 [B.5-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of CSA N287.1 is to provide general requirements to ensure that the design, construction, and testing of concrete containment structures will meet a quality and standard commensurate with the safety principles necessary to comply with the Canadian nuclear safety philosophy.*
>
> *CSA N287.1 specifies general requirements for the design, construction, testing, and commissioning of concrete containment structures for nuclear power plants designated as class containment and is directed to the owners, designers, manufacturers, fabricators, and constructors of the concrete components and parts.*

As identified in Section 1 of N287.1-14 [B.5-1]:

> *This Standard is applicable to new nuclear power plants' concrete containment structures to be built in Canada. Application of the Standard to concrete containment structures to be built outside of Canada is subject to approval of the authority having jurisdiction (AHJ). The application of the Standard to existing or operating nuclear power plants is as agreed upon by the owner/operator and the AHJ.*

CSA N287.1 is directly relevant to Safety Factor 1 (Plant Design).

CSA N287.1 is identified in Appendix E.1 of the R04 Pickering Licence Conditions Handbook [B.5-2] as "Guidance or Criteria". N287.1-14 is the fourth edition of this standard, which supersedes the previous editions published in 1993, 1982 and 1977 under the title "General requirements for Concrete Containment Structures for CANDU Nuclear Power Plants". The CSA N287.1-14 Impact Statement [B.5-3] provides a "Summary of significant changes from previous edition" which identifies several changes to the Standard as described in Section B.5.2.2 below.

The results of PSR1 CSA N287.1 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.5.2. As identified in Reference [B.5-4], the Pickering PSR2 review of CSA N287.1-14 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- <u>Compliance:</u> Compliance indicates that the change in the safety requirement, per the topical review, is met.

- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.5.2 Compliance Assessment for Pickering PSR2

B.5.2.1 Application of PSR1 Reviews

The versions of N287.1 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

As part of the Pickering B ISR Plant Design Safety Factor, OPG Report NK30-REP-03680-00001 R000, "Pickering NGS-B Integrated Safety Review - Plant Design Safety Factor" [B.5-5] performed a clause by clause review of N287.1-93 (R2004) [B.5-6] against OPG governance. NK30-REP-03680-00001 R000 identified minor deviations and concluded that the design of the existing Concrete Containment Structures (CCSs) at Pickering B are in general compliance with CSA N287.1-93. NK30-REP-03680-00001 R000 established that a number of Acceptable Deviations resulted from the review, as discussed below (text in italics taken verbatim from [B.5-5]):

- Clause 3.1.1 Classification of Class Containment: *The original and subsequent revisions of CSA N287 series of standards were issued after completion of design and construction of Pickering 'B' project. Therefore the description related to containment structure, parts, materials, design, fabrications, construction, inspection examination, testing and commissioning in accordance with the series of standards of CSA N287 were not available. At that time, the CCSs were designed to meet the requirements, the National Building Code (NBC) of Canada and Pickering B design guides and design requirements documents... The fact that "Classification of Class Containment" did not exist at the time of design is not safety significant. The CCSs have served their intended function satisfactorily for 25 years and remain sound and fully functional. In service inspections are being conducted in accordance with the requirements of CSA N287.7 and the resultant inspection reports attest to the quality of the design being maintained and satisfactorily meeting service requirements.*

- Clause 3.3 Jurisdictional Boundaries: *The definitions of the Jurisdictional Boundaries for portions of containment structure systems and components were not specifically identified at the time the CCSs were designed as the N287 standards had not yet been issued. Essentially, the design of all components or portions of the containment structure interfacing with nuclear systems are required to satisfy ASME Section III Class 2 or MC standards. Those interfacing with non-nuclear systems must conform to the standard for the applicable system. Note that Portions B and C of the CCSs, per clause definition, are considered outside the scope of this Standard. Therefore, the intent of this clause is considered to be met.*

- Clause 4.1.2.1 Design Specifications: *This clause specifies the general Design Specifications for Nuclear Power Plants. Pickering "B" CCSs underwent the process of design, fabrication, construction, installation, testing & commissioning as per existing NBCC (National Building Code of Canada) and ASME Section III (for some P/B embedded parts) requirements, Design guides and design requirements documents were prepared at the time and reflect the design of the CCSs as built. All such documents were reviewed and approved by professional engineers. Design Requirements Document NK30-DR-63420-10001 is a comprehensive design specification that covers all requirements listed in clause 5.1 for the NPC [Negative Pressure Containment] system, except those that apply to the vacuum building.*

- Clause 4.1.2.4 Site Seismicity: *Seismic assessment has been done for Pickering 'B'.*

- Clause 4.1.3 Quality Assurance: *OPG maintains a Quality Assurance program which complies with the CSA Standard N286. Although [vendor] has not reviewed this program, it is prepared to rely upon its knowledge that OPG maintains a QA program that meets the requirements of CAN/CSAN286.0 and that the program has been audited by the regulator. The intent of this clause is considered to be met.*

- Clause 4.2.1 Designer's Responsibility: *The designers of the Pickering B CCSs met NBC of Canada 1970 requirements and the requirements of various OPG design manuals and design requirements documents. The CCSs have consistently met their performance requirements throughout some 25 years of station operation and remain in good condition and fit for continuing service. The intent of this clause and the responsibilities listed in clauses 4.2.2 through 4.2.8 can be considered to be met.*

- Clause 5.1 Design Specifications: *This clause and the sub-clauses specify the general Design Specifications for Nuclear Power Plants. Pickering "B" has undergone all the processes listed in this clause during construction, installation, testing & commissioning in accordance with the existing NBCC (National Building Code of Canada) requirements at that time. The intent of this clause is considered to be met.*

- Clause 5.3 Drawings: *The drawings for project were developed manually whereas presently all the drawings are required to be developed electronically based on CAD software.*

- Clause 5.4 Design/Stress Report: *Pickering "B" Design / Stress Reports were prepared for Reactor Building & Vacuum Building and the documents are identified as NK30-PH-21140-01 & 973-NA44/NK30-25100 respectively. In addition, they are referenced in the Safety Report, Refer Part 1, Section 1.2.3.1 of Safety Report NK30-SR-01320-00001, Rev. 02. The document refers to the containment boundary formed by the Reactor Buildings, Pressure Relief Duct, Vacuum Building & Vacuum Ducts of CCSs. (The structures were designed for internal & external pressures which are detailed in this report.) Refer to NK30-DR-63240-10001, Section 6.*

- Clause 7.1 General: *Pickering 'B' Quality Assurance program was initially based on the project requirements of Part 4, 5, 6, 7 & 8 of NBC, Canada and supplemented in Design Manual. Later, the Quality Assurance program of CSA Z299.2 for manufacture and* *fabricated parts were applied as per the requirements. Visual inspection of concrete confirms that the concrete is in good condition and results of in-service leak tests have been satisfactory. This to be considered adequate for civil structures…. The Quality Assurance program applied to the design of the CCSs met the requirements of CSA Standard Z299.2. The generic requirements stipulated in Z299.0 were also considered at the time.*

- Clause 7.2 Quality Verification: *The Quality Verifications of Pickering "B" were prepared as per the project requirements in accordance with the Part 4, 5, 6, 7 & 8 of NBC, Canada. Visual inspection of concrete performed by qualified persons as part of the ongoing negative pressure containment system test program indicates that the CCSs remain in good condition.*

- Clause 7.3 Qualification of Inspection Personnel: *Inspection of the CCSs during construction and the inaugural inspection met the requirements of the NBC of Canada and inspectors carrying out the work were appropriately qualified. Inspectors who perform inspections as part of the on-going in-service and safety are competent by evidence of training and experience in the industry. Therefore the intent of this clause is considered to be met.*

- Clause 7.4 Quality Assurance Records: *The Quality Assurance Records will have been prepared for Pickering "B" CCSs in accordance with the OPG QA Program which complies with the Standard CSA N286.2 & CSA N286.3… the intent of this clause is considered to be met.*

OPG Report NK30-REP-03680-00015 R000, "Pickering NGS-B Integrated Safety Review (ISR) - Final ISR Report" [B.5-7] grouped the above findings into ISR Issues:

- 1-219/222/223/225/227, which identified these findings as Discrepancies with low safety significance (i.e., priority level 3 or 4) with no further action required, and

- 220/221/224/226/228/229/230/231/232, which provided additional justification for earlier classification as Acceptable Deviations.

The rationale for these findings being Acceptable Deviations is not impacted by Pickering NGS operation past 2020. CSA N287.1 applies to the design, construction, testing, and commissioning of CCSs. The CCSs at Pickering B were built and tested to meet 1970 National Building Code of Canada (NBCC) requirements [B.5-8], supplemented by specific loading requirements and the requirements of Design Manuals (e.g., see [B.5-9], [B.5-10], [B.5-11], [B.5-12]) and Design Guides (e.g., see [B.5-13], [B.5-14], [B.5-15]). The original Pickering concrete specifications (L-715-80 [B.5-16] and NK30-LH-20541-01 [B.5-17]) included requirements for quality control and compliance with CSA A23.1, A23.2 and A23.3 (which address concrete materials, methods of concrete construction and test methods and standard practices for concrete). As such, the standards that applied during original construction of Pickering NGS included requirements for tests and quality control procedures to ensure that the concrete used in the as-built structures met the original design requirements. Ongoing confirmation that the Pickering NGS CCSs remain fit for service is demonstrated via the following:

- As required by N-PROG-MA-0017 R008 [B.5-18]:
  - Periodic examinations of in-service inspections and positive leakage rate testing of CCSs that are designated as class containment components are performed in accordance with the requirements of CSA N287.7, "In Service Examination and Testing Requirements for Concrete Containment Structures for CANDU Nuclear Power Plants". N-PROC-MA-0066 R005, "Administrative Requirements for In-Service Examination and Testing for Concrete Containment Structures" [B.5-19] describes the administrative process and the roles of various organizations across OPG Nuclear involved in the execution of N-PROG-MA-0017 R008 in order to comply with the requirements of CSA N287.7.
  - Periodic inspection of containment system metallic and plastic components (including the containment pressure suppression systems) is performed in accordance with the requirements of CSA N285.5, "Periodic inspection of CANDU Nuclear Power Plant Containment Components". N-PROC-MA-0064 R005, "Administrative Requirements for the Periodic Inspection of Nuclear Power Plant Containment Components" [B.5-20], describes the administrative process and the roles of various organizations across OPG Nuclear involved in the execution of the Program in order to comply with the requirements of CSA N285.5.
- With respect to aging management, N-PROG-MA-0017 R008 interfaces with the Integrated Aging Management Program to evaluate the condition of equipment (including containment structures) on an ongoing basis as defined by component programs, including management of equipment aging activities that: 1) identify aging related degradation mechanisms, 2) define maintenance, inspection, test, and other activities, and 3) initiate preventive action to preclude component or system failure. A condition assessment process is used to evaluate the health of critical components and establish actions necessary to maintain long-term health. Condition assessments are prepared in accordance with N-PROC-MP-0060 R005 B, "Aging Management Process" [B.5-21]. Requirements for reporting (such as summarizing significant aging issues in component health reports) are identified in this procedure.
- Non-Destructive Examination required for the periodic inspection of containment components is performed in accordance with N-STD-MA-0021 R001, "Non-Destructive Examination" [B.5-22] to ensure that these examinations meet code and jurisdictional requirements.

N-PROG-MP-0001 R014, "Engineering Change Control" [B.5-23], N-FORM-10959 R016, "Design Scoping Checklist" [B.5-24] and N-PROC-MP-0090 R014, "Modification Process" [B.5-25] ensure that any future design changes made to the CCSs comply with modern applicable codes, standards, and regulations (including CSA N287.1-14, per OPG Guideline N-GUID-00590-00002 R001, "Code over Code Review - Guideline" [B.5-26]) as applicable.

The above-mentioned Programs, Procedures and Standards are credited with the ability to detect and monitor any safety significant degradation mechanisms and thus to provide assurance of continued fitness for service of the Pickering NGS CCSs.

Pickering Units 1,4

Pickering A Basis for Return to Service identified N287.1-93 [B.5-6] for review based on a "Direct & Immediate Effect on Installed Design Features" [B.5-27]. AECL Assessment Document 44RS-00531-ASD-001 Rev. 04 [B.5-28] documents a clause by clause review against N287.1-93. 44RS-00531-ASD-001 Rev. 04 concluded:

> *Based on the present study and the evaluation of documents, it is concluded that the design of Pickering 'A' containment structure meets the intent of the current CSA standards* [CSA N287.1 and N287.3]*. As the design was done years ago utilizing NBC 1965, it is not possible to meet every aspect of newly developed codes. However after a review of the requirements in old and new codes and project specific documents it can be concluded that the changes and additions that have occurred in new codes do not have impact on the performance of the containment structure, namely the pressure retaining capability and leak tightness… The compliance discussion provided justifies that the containment structure for Pickering A Nuclear Power Plant meets the intent of the current CSA standards. Therefore, no special measures or recommendations are necessary.*

Similar to the Pickering B ISR review of N287.1-93, 44RS-00531-ASD-001 Rev. 04 identified a number of areas Pickering A was considered to be in "Indirect Compliance"; these were primarily related to the inability to recover old records or to demonstrate the standard the in-situ plant was built to. The rationale for these findings being Indirect Compliances was reviewed for PSR2 and confirmed to not be impacted by Pickering NGS operation past 2020. The concrete structures at Pickering A were built and tested to meet the 1965 NBCC requirements [B.5-29] and associated CSA A23 Series Standards, supplemented by specific loading requirements and the requirements of Design Manuals (e.g., see [B.5-30], [B.5-31], [B.5-32], [B.5-33], [B.5-34], [B.5-35]). As discussed earlier, ongoing confirmation that the Pickering NGS CCSs remain fit for service is demonstrated via periodic inspection and in-service testing. Further, the Engineering Change Control (ECC) process ensures that any future design changes made to the CCSs comply with the latest version of N287.1 [B.5-26] as applicable.

Darlington NGS

A review against CSA N287.1-93 (R2004) [B.5-6] was performed as part of the Darlington ISR. This review is documented in OPG Report NK38-REP-03680-10034 R000 [B.5-36] which concluded "The review did not identify any ISR Gaps and found that Darlington NGS was compliant with CAN/CSA-N287.1-93." CNSC staff comments and OPG responses related to the N287.1-93 code review were documented in OPG Report NK38-REP-03680-10034-ADD-001 R000, "Addendum to the CSA N287.1-93 Code Review Report for Darlington ISR" [B.5-37], which identified three new gaps to reflect CNSC/OPG dialogue.

Similar to the Pickering Units 5-8 and 1,4 reviews above, the Darlington gaps against N287.1 were related to the retrievability of old records and the ability to demonstrate the standard the in-situ plant was built to. In addition, similar to the previously mentioned Pickering reviews, it was argued in OPG Report NK38-REP-03680-10104-ADD-01 R000, "Darlington NGS Integrated Safety Review (ISR) - Final ISR Report Addendum" [B.5-38] that the changes in N287.1 will not impact the safe operation of the CCSs given robust design practices at the time, together with ongoing periodic inspection and in-service testing. As a result, the gaps were ranked as low safety significance and resolved to be Acceptable Deviations [B.5-38]. Therefore, there are no PSR2 gaps associated with the Darlington ISR assessment of N287.1-93.

B.5.2.2 Application of Post PSR1 Reviews

Per the CSA N287.1-14 Impact Statement [B.5-3], the following is a summary of the significant changes from the previous edition of the standard (N287.1-93 (R2004) [B.5-6], which was reviewed as part of PSR1):

- The scope has been broadened so that the standard applies to CCSs for nuclear power plants regardless of plant design type (technology neutral). This is reflected in the changed title of the standard.
- Additional figures have been included to clarify the definitions of jurisdictional boundaries.
- Requirements for aging management and repairs have been added; Consideration to aging is given, especially in view of the life extensions.
- In-service examination and testing requirements have been added, to clarify the objectives of in-service examination and defines the responsibilities of the personnel involved.
- Requirements for personnel qualification to perform construction inspections as well as in-service examinations and testing have been added.
- Reference standards and definitions are updated to current standards and to align with other N287 standards.
- Adjustments and verification for consistency with updated CNSC regulatory and guidance documents and international safety standards.

OPG Report N-REP-00590-00004 R000, "Code-Over-Code Review Report: N287.1 for the Year 2014" [B.5-39] provides a clause by clause review of N287.1-14 versus N287.1-93, and states:

> This code over code review has *identified significant technical changes and appropriate mitigation plans have been identified, in Appendix A. For details of mitigation plans see items #3, 13, 14, 22-24, and 28-30 of table in Appendix A.*

The following table provides extracts from the Appendix A table [B.5-39] outlining the changes and associated mitigation plans:

N287.1 Clause	Change	Significance	Mitigation
4.1.3 Concrete containment structures and concrete components affecting the leak-tightness of the containment boundary shall be designed to allow leakage rate testing (LRT) …	The new clause requires penetrations to CCSs be able to individually leak testable, where practical [sic].	Although unlikely, the requirement may be applicable to any newly designed penetrations for containment structure as part of a modification to existing power plants.	This new requirement will be included in the next revision of N-LIST-00590-00001.
6.2 Design specifications The design specifications shall include, but not be limited to …	The existing clause has been modified to include 4 new sub-clauses in design specifications.	These new requirements apply to design specifications for new build or modifications of existing CCSs.	This new requirement will be included in the next revision of N-LIST-00590-00001.
6.4 Drawings g) the position, details, and size of any modular-type structures	New bullet is added to show location of modular type structures in containment structures.	New requirement.	This new requirement will be included in the next revision of N-LIST-00590-00001.
7.2.2.1 Commissioning documents shall …	New bullets are added to include more information in commissioning documents.	New requirement, may apply to modifications carried out to existing power plants.	This new requirement will be included in the next revision of N-LIST-00590-00001.
7.2.3 Test procedures i) personnel qualification requirements;	New bullet is added to include personnel qualification requirements in commissioning test procedures.	New requirement, may apply to modifications carried out to existing power plants.	This new requirement will be included in the next revision of N-LIST-00590-00001.
7.2.4 Report The commissioning report shall include …	New bullets are added to include more information in commissioning reports.	New requirement, may apply to modifications carried out to existing power plants.	This new requirement will be included in the next revision of N-LIST-00590-00001.
9.3.4.2 To qualify as a Level I inspector, a person shall have completed …	The new clause is more restrictive in terms of personnel qualifications, applicable to inspectors performing inspections related to modifications or new construction.	New requirement.	This new requirement will be included in the next revision of N-LIST-00590-00001.

N287.1 Clause	Change	Significance	Mitigation
9.3.4.4 To qualify as a Level II inspector, a person shall have completed …	The new clause is more restrictive in terms of personnel qualifications, applicable to inspectors performing inspections related to modifications or new construction.	New requirement.	This new requirement will be included in the next revision of N-LIST-00590-00001.
9.3.4.6 To qualify as a Level III inspector, a person shall have completed …	The new clause is more restrictive in terms of personnel qualifications, applicable to inspectors performing inspections related to modifications or new construction.	New requirement.	This new requirement will be included in the next revision of N-LIST-00590-00001.

The mitigation instituted for each gap was to include the changes to CSA N287.1-14 in the next revision of N-LIST-00590-00001 R002, "List of Significant Technical Changes from Code-over-Code Review" [B.5-40]. All modifications require review of this document as identified in N-FORM-10959 R016, "Design Scoping Checklist" [B.5-24], as per N-PROC-MP-0090 R014, "Modification Process" [B.5-25] (N-FORM-10959 R016 Section 2.19 requires that a review of N-LIST-00590-00001 R002 "shall be completed to determine if any code change improvement actions apply to the modification"). As a result, significant technical changes will be applied, as appropriate, for modifications to existing Pickering NGS installations going forward in accordance with OPG governance. Based on the above, CSA N287.1-14 has no gaps that need to be addressed for Pickering NGS, unless modifications are made in the future. Therefore, there are no gaps for PSR2 against the changes in N287.1-14.

In summary, the ECC process (which includes review of N-LIST-00590-00001 R002 [B.5-40]), together with a yearly examination of any incremental (Code-over-Code) review requirements due to changes to N287.1 [B.5-26], ensures that any design changes made to the Pickering NGS CCSs comply with the latest version of N287.1 going forward, as applicable. With respect to the retroactive application to Pickering NGS, it is not practicable to make design changes to CCSs without rebuilding them, and ongoing confirmation that the CCSs remain fit for service is demonstrated via periodic inspections and in-service testing. Therefore, there are no PSR2 gaps for Pickering NGS compliance with CSA N287.1-14.

B.5.3 Compliance Summary for Pickering PSR2

There are no PSR2 gaps for CSA N287.1-14 [B.5-1]. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with CSA N287.1-14.

B.6 CSA N287.3-14, "Design Requirements for Concrete Containment Structures for Nuclear Power Plants"

B.6.1 Background

The following, paraphrased from the Preface of CSA N287.3-14 [B.6-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of CSA N287.3 is to ensure concrete containment structures are designed for sufficient strength, structural integrity, and required leak-tightness under operating and test conditions, postulated accident, environmental conditions, or combinations thereof.*
>
> *CSA N287.3 provides requirements for the design of concrete containment structures of a containment system, designated as "class containment" components and parts as defined in CSA N287.1, and addresses their beyond design basis assessment.*

As identified in Section 1 of N287.3-14 [B.6-1]:

> *This Standard is applicable to new nuclear power plants' concrete containment structures to be built in Canada. Application of the Standard to concrete containment structures to be built outside Canada is subject to approval of the authority having jurisdiction (AHJ). The application of the Standard to existing or operating nuclear power plants is as agreed upon by the owner/operator and the AHJ.*

CSA N287.3 is directly relevant to Safety Factor 1 (Plant Design).

CSA N287.3 is identified in Appendix E.1 of the R04 Pickering Licence Conditions Handbook [B.6-2] as "Guidance or Criteria". N287.3-14 is the fourth edition of this standard which supersedes the previous editions published in 1993, 1982 and 1978 under the title "Design Requirements for Concrete Containment Structures for CANDU nuclear power plants". The CSA N287.3-14 Impact Statement [B.6-3] provides a "Summary of significant changes from previous edition" which identifies several changes to the Standard as described in Section B.6.2.2 below.

The results of PSR1 CSA N287.3 reviews (Pickering A Return to Service assessments, and Pickering and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.6.2. As identified in Reference [B.6-4], the Pickering PSR2 review of CSA N287.3-14 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.
- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.6.2 Compliance Assessment for Pickering PSR2

B.6.2.1 Application of PSR1 Reviews

The versions of N287.3 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

<u>Pickering Units 5-8</u>

As part of the Pickering B ISR Plant Design Safety Factor, OPG Report NK30-REP-03680-00001 R000 [B.6-5] performed a clause by clause review of N287.3-93 (R2004) [B.6-6] against OPG governance. NK30-REP-03680-00001 R000 concluded:

> *The compliance evaluation of the CSA N287.3-93 Standard has determined that in itself it does not introduce any new requirements that impact the design basis of the CCSs* [Concrete Containment Structures]*. No discrepancies were identified. However, a number of clauses of CSA N287.3 refer to CSA A23.1, CSA A23.3 and other standards. These standards also contain design requirements and they have been revised as recently as 2005. They may, therefore, contain requirements that were not present in the versions of these standards that applied at the time the CCSs were designed and built.* [The vendor] *has not conducted a review of A23.1, A23.3 or any other standard referred to, as it is not part of its current scope of work.*
>
> *… It is noted that the objectives of an independent safety review are to assess the fitness of the existing plant design for life extension and then to establish a plan to ensure continued fitness for service. It is also noted that it is not feasible to make design changes that would extend the life of the CCSs without rebuilding them. Hence, conducting a detailed assessment of the standards called up in CSA N287.3 to determine what new design requirements have been introduced would provide no safety benefit and would not help to achieve the objectives of the ISR.*

A large number of findings were identified in the NK30-REP-03680-00001 R000 review, which generally related to reference in N287.3 to other standards that apply to CCS design (including CSA A23 and the N287 Series of standards), as well as considerations for seismic ground motions. All findings were assessed to be Acceptable Deviations given robust design practices at the time, together with ongoing periodic inspections and in-service testing. OPG Report NK30-REP-03680-00015 R000, "Pickering NGS-B Integrated Safety Review (ISR) - Final ISR Report" [B.6-7] grouped the findings into ISR Issues 1-274/276, I-253 to -273 and 1-275/277/278/279, and confirmed their status as Acceptable Deviations with very low safety significance (i.e., priority level 4) with no further action required.

The rationale for these findings being Acceptable Deviations is not impacted by Pickering NGS operation past 2020. CSA N287.3 ensures CCSs are designed for sufficient strength, structural integrity, and required leak-tightness under operating and test conditions, postulated accident and environmental conditions. The CCSs at Pickering B were built and tested to meet 1970

National Building Code of Canada (NBCC) requirements [B.6-8], supplemented by specific loading requirements and the requirements of Design Manuals (e.g., see [B.6-9], [B.6-10], [B.6-11], [B.6-12]) and Design Guides (e.g., see [B.6-13], [B.6-14], [B.6-15]). The original Pickering concrete specifications (L-715-80 [B.6-16] and NK30-LH-20541-01 [B.6-17]) included requirements for quality control and compliance with CSA A23.1, A23.2 and A23.3 (which address concrete materials, methods of concrete construction and test methods and standard practices for concrete). As such, the standards that applied during original construction of Pickering NGS included requirements for tests and quality control procedures to ensure that the concrete used in the as-built structures met the original design requirements. Ongoing confirmation that the Pickering NGS CCSs remain fit for service is demonstrated via the following:

- As required by N-PROG-MA-0017 R008 [B.6-18]:

    - Periodic examinations of in-service inspections and positive leakage rate testing of CCSs that are designated as class containment components are performed in accordance with the requirements of CSA N287.7, "In Service Examination and Testing Requirements for Concrete Containment Structures for CANDU Nuclear Power Plants". N-PROC-MA-0066 R005, "Administrative Requirements for In-Service Examination and Testing for Concrete Containment Structures" [B.6-19] describes the administrative process and the roles of various organizations across OPG Nuclear involved in the execution of N-PROG-MA-0017 R008 in order to comply with the requirements of CSA N287.7.

    - Periodic inspection of containment system metallic and plastic components (including the containment pressure suppression systems) is performed in accordance with the requirements of CSA N285.5, "Periodic inspection of CANDU Nuclear Power Plant Containment Components". N-PROC-MA-0064 R005, "Administrative Requirements for the Periodic Inspection of Nuclear Power Plant Containment Components" [B.6-20], describes the administrative process and the roles of various organizations across OPG Nuclear involved in the execution of the Program in order to comply with the requirements of CSA N285.5.

- With respect to aging management, N-PROG-MA-0017 R008 interfaces with the Integrated Aging Management Program to evaluate the condition of equipment (including containment structures) on an ongoing basis as defined by component programs, including management of equipment aging activities that: 1) identify aging related degradation mechanisms, 2) define maintenance, inspection, test, and other activities, and 3) initiate preventive action to preclude component or system failure. A condition assessment process is used to evaluate the health of critical components and establish actions necessary to maintain long-term health. Condition assessments are prepared in accordance with N-PROC-MP-0060 R005 B, "Aging Management Process" [B.6-21]. Requirements for reporting (such as summarizing significant aging issues in component health reports) are identified in this procedure.

- Non-Destructive Examination required for the periodic inspection of containment components is performed in accordance with N-STD-MA-0021 R001, "Non-Destructive

Examination" [B.6-22] to ensure that these examinations meet code and jurisdictional requirements.

N-PROG-MP-0001 R014, "Engineering Change Control" [B.6-23], N-FORM-10959 R016, "Design Scoping Checklist" [B.6-24] and N-PROC-MP-0090 R014, "Modification Process" [B.6-25] ensure that any future design changes made to the CCSs comply with modern applicable codes, standards, and regulations (including CSA N287.3-14, per OPG Guideline N-GUID-00590-00002 R001, "Code over Code Review - Guideline" [B.6-26]) as applicable.

The above-mentioned Programs, Procedures and Standards are credited with the ability to detect and monitor any safety significant degradation mechanisms and thus to provide assurance of continued fitness for service of the Pickering NGS CCSs.

<u>Pickering Units 1,4</u>

Pickering A Basis for Return to Service identified N287.3-93 [B.6-6] for review based on a "Direct & Immediate Effect on Installed Design Features" [B.6-27]. AECL Assessment Document 44RS-00531-ASD-001 Rev. 04 [B.6-28] documents the clause by clause review of N287.3-93. 44RS-00531-ASD-001 Rev. 04 concluded:

> *Based on the present study and the evaluation of documents, it is concluded that the design of Pickering 'A' containment structure meets the intent of the current CSA standards* [CSA N287.1 and N287.3]*. As the design was done years ago utilizing NBC 1965, it is not possible to meet every aspect of newly developed codes. However after a review of the requirements in old and new codes and project specific documents it can be concluded that the changes and additions that have occurred in new codes do not have impact on the performance of the containment structure, namely the pressure retaining capability and leak tightness…*
>
> *The compliance discussion provided justifies that the containment structure for Pickering A Nuclear Power Plant meets the intent of the current CSA standards. Therefore, no special measures or recommendations are necessary.*

Similar to the Pickering B ISR review of N287.3-93, 44RS-00531-ASD-001 Rev. 04 identified a number of areas in which Pickering A was considered to be in "Indirect Compliance". The rationale for these findings being Indirect Compliances was reviewed for PSR2 and confirmed to not be impacted by Pickering NGS operation past 2020. The concrete structures at Pickering A were built and tested to meet the 1965 NBCC requirements [B.6-29] and associated CSA A23 Series Standards, supplemented by specific loading requirements and the requirements of Design Manuals (e.g., see [B.6-30], [B.6-31], [B.6-32], [B.6-33], [B.6-34], [B.6-35]). As discussed earlier, ongoing confirmation that the Pickering NGS CCSs remain fit for service is demonstrated via periodic inspection and in-service testing. Further, the Engineering Change Control (ECC) process ensures that any future design changes made to the CCSs comply with the latest version of N287.3 [B.6-26] as applicable.

Darlington NGS

A review against N287.3-93 (R2004) [B.6-6] was performed as part of the Darlington ISR. This review is documented in OPG Report NK38-REP-03680-10036 R000 [B.6-36] which concluded:

> *Based on the results of the review of Darlington NGS concrete containment structures against CSA Standard N287.3-93 (R2004), it is declared that Darlington NGS concrete containment structures are compliant, except for the gaps identified … by comparing the clauses of CSA Preliminary Standard N287.3-1978 which is the original design standard against the clauses of CSA Standard N287.3-93 (R2004). After reviewing the design related documents of the Darlington NGS concrete containment structures, the gaps were confirmed.*

OPG Report NK38-REP-03680-10036 R000 also includes an appendix with gap revisions made subsequent to the code review report. The Darlington gaps against N287.3 were related to new requirements involving anchorage systems, redundancy of mechanical splices, and maximum concrete tensile stresses for liners of CCSs. OPG Report NK38-REP-03680-10201 R001, "ISR Open Issues and Acceptable Deviations - Adequacy Review" [B.6-37] stated that all three of these gaps were Acceptable Deviations, providing arguments similar to those made for the Pickering Units 5-8 and 1,4 reviews discussed above, i.e.:

- although there were no prescriptive specifications for, and testing of, the materials used in concrete anchors at the time of construction, manufacturers did meet testing requirements at that time; and

- the periodic inspections and routine leakage tests of the containment envelope verify that there is no significant deterioration in the integrity of the CCSs, and any potential degradation from an overall concrete containment perspective will be observed and action taken accordingly if required.

These arguments also apply to Pickering NGS.

CNSC staff comments and OPG responses related to the CSA N287.3-93 code review were documented in OPG Report NK38-REP-03680-10036-ADD-001 R000 [B.6-38]. Two new gaps were opened to reflect CNSC/OPG dialogue which related to documentation for concrete reinforcement covers and anchorage systems. OPG Report NK38-REP-03680-10201 R001 [B.6-37] was follow-up work to demonstrate that the in-situ plant meets requirements. This work was tracked under Action Request (AR) #28153581 and calculations were subsequently completed which demonstrated that: a) anchorage systems meet the intent of N287.3-93, and b) the construction specifications for concrete covers exceeded N287.3-93 requirements. Both gaps were subsequently closed. The Pickering B ISR and Pickering A Return to Service assessments previously assessed against these N287.3-93 clauses were classified either as Acceptable Deviations or Indirect Compliances, citing the rationale discussed earlier. As a result, there are no PSR2 gaps which result from review of the Darlington ISR results.

B.6.2.2 Application of Post PSR1 Reviews

Per the CSA N287.3-14 Impact Statement [B.6-3], the following is a summary of the significant changes from the previous edition of the standard (N287.3-93 (R2004) [B.6-6], which was reviewed as part of PSR1):

- *The scope has been broadened so that the standard applies to concrete containment structures for nuclear power plants regardless of plant design type (technology neutral). This is reflected in the changed title of the standard.*
- *The new edition clarifies several ambiguities in the previous edition. These include several definitions, load and load combinations, and stress and strain limits.*
- *New load and load factors are introduced. Three additional load combinations are defined to represent the construction loads.*
- *New requirements for beyond design basis are introduced by adding a new Annex. A new Annex C provides guidelines for predicting the ultimate pressure capacity of concrete containments. This new Annex provides a measure of the safety margin above the design-basis internal accident pressure.*
- *The new edition considers the requirements in the revised A23.3-04 (R2010).*
- *Design requirements for openings or penetrations, penetration assemblies, and attachments are added.*
- *Significant changes are made to the clause on Anchorage. The Annex D in A23.3-04 (R2010) has been adopted and the sections are revised to reflect this change.*
- *New requirements on liners are added. Strain limits for service load category is defined for metallic liners.*
- *New requirements for serviceability are added. Stress limits for service load category are defined.*
- *Reference standards and definitions are updated.*
- *New definitions and list of symbols are added.*
- *New requirements for seismic design of walls, slabs, shells, and domes are introduced.*

OPG Report N-REP-00590-00005 R000, "Code-Over-Code Review Report: N287.3 for the Year 2014" [B.6-39] provides a clause by clause review of N287.3-14 versus N287.3-93, and states:

> *This code over code review has identified significant technical changes and appropriate mitigation plans have been identified, in Appendix A. Some of the significant changes can only be met during design, construction, or fabrication of new concrete containment structures, such as new build. Such changes have been*

identified to be non-applicable to existing OPGN facilities. Mitigation plans, for requirements applicable to existing OPGN facilities, have been detailed in Appendix A.

The following table provides extracts from the Appendix A table [B.6-39] outlining the changes and mitigation plans:

N287.3-14 Clause	Change	Significance	Mitigation
6.5.6 Penetration assemblies shall be analyzed and designed following the methodologies and procedures specified in …	Further clarifications have been added as a requirement.	New requirement can be met during design of new nuclear power plants with liner. May apply to modifications done in existing facilities.	This new requirement will be added in the revision to the N-LIST-00590-00001.
6.5.7 When attachments in the form of steel structures are mounted onto the metal liner or containment wall, they shall be designed and analyzed…	Requirement applicable to design of attachments to steel liner have been added.	New Requirement may be applicable to any future modification done in existing facilities.	This new requirement will be added in the revision to the N-LIST-00590-00001.
Table 7.1 Construction Dead Load (D) factor = 1.4	A new load combination is introduced in accordance with NBCC 2010.	New Requirement may be applicable to any future modification done in existing facilities	This new requirement will be added in the revision to the N-LIST-00590-00001.
8.2.1.2 For the service load category (factored), the design shall also meet the requirements of CAN/CSA-A23.3	This new Requirement applies for design of concrete containment for new power plants.	Any potential Modifications may have to comply with this requirement.	This new requirement will be added in the revision to the N-LIST-00590-00001.
9.2.3 Companies responsible for welded splices and welded connections shall comply with CSA W186.	Qualifications for companies have been included in.	Any potential modifications may have to comply with this requirement.	This new requirement will be added in the revision to the N-LIST-00590-00001.
11.6.3 Flat slabs with or without beams shall be reinforced and detailed in accordance with …	New clause provides reinforcement detailing provisions during construction/ design of new CCSs. This requirement cannot be applied to existing concrete structures.	This requirement can be met by new build power plants. This new requirement may apply to existing nuclear power plants.	This new requirement will be added in the revision to the N-LIST-00590-00001.

N287.3-14 Clause	Change	Significance	Mitigation
13.3.1.5 Penetration assemblies shall be designed to accommodate all design loads and deformations to ensure structural integrity and leak-tightness.	New requirement for design of penetrations for CCSs.	The new requirement may be applicable to modifications to existing CCSs.	This new requirement will be added in the revision to the N-LIST-00590-00001.
13.3.4.2 Consideration of the following effects that can cause shear loads and displacements shall include …	Three new bullets have been added to address design of embedded parts.	May apply to design of modifications for existing plants.	This new requirement will be added in the revision to the N-LIST-00590-00001.
13.3.5.4 Companies responsible for the welding of metallic parts shall comply with the requirements of CSA W47.1 Division 1 or 2.	Clarification to use W47.1 for welding companies' qualifications.	May apply to modification of existing plants.	This new requirement will be added in the revision to the N-LIST-00590-00001.
14.1 Objective … requirements for the design of cast-in and post-installed anchors and inserts used in a nuclear containment structure …	Anchorage design requirements have been updated to align with CSA A23.3.	It may apply to modifications to concrete structures involving anchorage and a Document Change Request (DCR) has been initiated to update direction on use of anchors in containment to comply with CSA N287.3-14.	This new requirement will be added in the revision to the N-LIST-00590-00001.
14.2.1 Anchor and anchor groups shall be designed for critical effects of factored loads as determined by elastic analysis. …	Anchorage design requirements have been updated to align with CSA A23.3.	It may apply to modifications to concrete Structures involving anchorage and a DCR has been initiated to update direction on use of anchors in containment to comply with CSA N287.3-14.	This new requirement will be added in the revision to the N-LIST-00590-00001.
14.2.2 Post-installed anchors shall be designed assuming cracked concrete unless it can be demonstrated …	Anchorage design requirements have been updated to align with CSA A23.3.	It may apply to modifications to concrete Structures involving anchorage and a DCR has been initiated to update direction on use of	This new requirement will be added in the revision to the N-LIST-00590-00001.

N287.3-14 Clause	Change	Significance	Mitigation
		anchors in containment to comply with CSA N287.3-14.	
14.3.1 The design of concrete anchorage systems shall be in accordance with CAN/CSAA23.3 …	Anchorage design requirements have been updated to align with CSA A23.3.	It may apply to modifications to concrete Structures involving anchorage and a DCR has been initiated to update direction on use of anchors in containment to comply with CSA N287.3-14.	This new requirement will be added in the revision to the N-LIST-00590-00001.
14.3.2.2 When shear is transmitted by the bearing of shear lugs and embedded plates on the concrete, the factored concrete breakout resistance shall …	Anchorage design requirements have been updated to align with CSA A23.3.	It may apply to modifications to concrete Structures involving anchorage and a DCR has been initiated to update direction on use of anchors in containment to comply with CSA N287.3-14.	This new requirement will be added in the revision to the N-LIST-00590-00001.
Table B1 Recommended Dynamic Increase Factors (DIF)	New clause/ Table has added DIF factors for Carbon steel and Stainless steel.	Applies to design of modifications, if applicable.	This new requirement will be added in the revision to the N-LIST-00590-00001.
Table B2 Permissible Ductility Ratios for Beams, Slabs, and Walls	New requirements have increased ductility ratios.	Applies to design of modifications, if applicable.	This new requirement will be added in the revision to the N-LIST-00590-00001.
B.4.2.4 In the design, the required barrier or wall thickness to prevent perforation shall …	New requirement	Applies to design of modifications, if applicable.	This new requirement will be added in the revision to the N-LIST-00590-00001.
B.4.3.2 When the force-time history is not used (e.g., in the simplified method), the conservation of momentum and energy may be applied …	New requirement	Applies to design of modifications, if applicable	This new requirement will be added in the revision to the N-LIST-00590-00001.

The mitigation instituted for these gaps was to include the changes to CSA N287.3-14 in the next revision of N-LIST-00590-00001 R002, "List of Significant Technical Changes from Code-over-Code Reviews" [B.6-40]. All modifications require review of this document as identified in N-FORM-10959 R016, "Design Scoping Checklist" [B.6-24], as per N-PROC-MP-0090 R014, "Modification Process" [B.6-25] (N-FORM-10959 R016 Section 2.19 requires that a review of N-LIST-00590-00001 R002 "shall be completed to determine if any code change improvement actions apply to the modification"). As a result, significant technical changes will be applied, as appropriate, for modifications to existing Pickering NGS installations going forward in accordance with OPG governance.

It is noted that Code-over-Code report N-REP-00590-00005 R000 [B.6-39] also identified a number of changes that can only be met during design, construction, or fabrication of new CCSs (i.e., clauses 9.3.2.3 (mechanical splices), 11.5 (frame joints), 11.6.2 (flat shear walls), 11.6.4/.5/.6 (shear strength of curved walls), 13.3.2.1 (liner requirements) and A.3.2.3 (abnormal/environmental load combinations)); these changes were identified to be non-applicable to existing OPG Nuclear facilities and therefore not placed in N-LIST-00590-00001 R002. Although these changes have not been listed in N-LIST-00590-00001 R002, it is generally not practicable to make design changes to CCSs without rebuilding them. As a result, CSA N287.3-14 has no gaps that need to be addressed for the existing stations, unless modifications are made in the future. Therefore, there are no gaps for PSR2 against the changes in N287.3-14.

In summary, the ECC process (which includes review of N-LIST-00590-00001 R002 [B.6-40]), together with a yearly examination [B.6-26] of any incremental (Code-over-Code) review requirements due to changes to N287.3, ensures that any design changes made to the Pickering NGS CCSs comply with the latest version of N287.3 going forward, as applicable. With respect to the retroactive application to Pickering NGS, it is not practicable to make design changes to CCSs without rebuilding them, and ongoing confirmation that the CCSs remain fit for service is demonstrated via periodic inspections and in-service testing. Therefore, there are no PSR2 gaps for Pickering NGS compliance with CSA N287.3-14.

B.6.3 Compliance Summary for Pickering PSR2

There are no PSR2 gaps for CSA N287.3-14 [B.6-1]. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with CSA N287.3-14.

B.7 CSA N287.5-11, "Examination and Testing Requirements for Concrete Containment Structures for Nuclear Power Plants"

B.7.1 Background

The following, paraphrased from the Preface of CSA N287.5-11 (R2016) [B.7-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of CSA N287.5 is to ensure concrete containment structures are built using techniques and work practises that meet the quality and standards commensurate with the principles necessary to comply with the Canadian nuclear safety philosophy through specification of examination and testing requirements.*
>
> *CSA N287.5 specifies examination and testing requirements that apply to the work of any organization participating in the construction, fabrication, or installation of parts or components of concrete containment structures for nuclear power plants that are designated as class containment, as well as the personnel qualification requirements for work pertaining to this standard.*

CSA N287.5-11 is directly relevant to Safety Factor 1 (Plant Design) and Safety Factor 2 (Actual Condition of Structures, Systems and Components).

CSA N287.5 is identified in Appendix E.1 of the R04 Pickering Licence Conditions Handbook [B.7-2] as "Guidance or Criteria". N287.5-11, which was reaffirmed in 2016, is the third edition of this standard which supersedes the previous editions, published in 1993 and 1981, under the title "Examination and Testing Requirements for Concrete Containment Structures for CANDU Nuclear Power Plants". The CSA N287.5-11 Impact Statement [B.7-3] provides a "Summary of significant changes from the previous edition" which identifies several changes to the Standard as described in Section B.7.2 below.

The results of PSR1 CSA N287.5 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.7.2. As identified in Reference [B.7-4], the Pickering PSR2 review of CSA N287.5-11 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.

- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.7.2 Compliance Assessment for Pickering PSR2

B.7.2.1 Application of PSR1 Reviews

The versions of N287.5 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

The Pickering B ISR did not undertake a compliance assessment against CSA N287.5. Per OPG Report NK30-REP-03680-00002 R000, "Pickering NGS-B Integrated Safety Review - Actual Condition of Systems, Structures and Components Safety Factor Report" [B.7-5]:

> *CSA N287.5 deals with the requirements for examination and testing of concrete during the construction of the containment system. In addition to the examination and testing performed during construction, the commissioning tests, in-service inspections and in-service testing, ensure that the containment system meets its design requirements. Therefore, this standard is not included in the scope of the review documented in this report.*

The date of issue of the Construction License for Pickering B was July 19, 1974, and CSA N287.5 is not listed as "codes and standards applicable to the NPCS [Negative Pressure Containment System] design, in accordance with the Code Effective Date/Construction Licence date/date of original design" [B.7-6]. CSA N287.5 applies to the testing of Concrete Containment Structures (CCSs) during initial construction, installation and fabrication. The CCSs at Pickering B were built and tested to meet 1970 National Building Code of Canada (NBCC) requirements [B.7-7], supplemented by specific loading requirements and the requirements of Design Manuals (e.g., see [B.7-8], [B.7-9], [B.7-10], [B.7-11]) and Design Guides (e.g., see [B.7-12], [B.7-13], [B.7-14]). The original Pickering concrete specifications (L-715-80 [B.7-15] and NK30-LH-20541-01 [B.7-16]) included requirements for quality control and compliance with CSA A23.1, A23.2 and A23.3 (which address concrete materials, methods of concrete construction and test methods and standard practices for concrete)[9].

---

[9] Section 2A2 of NK30-LH-20541-01 [B.7-16] identifies all of the applicable laws, standards, codes, authorities and technical organizations referenced in the concrete tendering and contract documents, including CSA A5, A23 Series, A266 Series, American Concrete Institute and American Society for Testing and Materials standards. NK30-LH-20541-01 was reviewed for major differences against the requirements of CSA N287.5-11 (R2016) [B.7-1] as part of PSR2, and is deemed to meet the intent of Clause 4 (General Requirements), Clause 5 (Concrete), Clause 6 (Reinforcement), Clause 7 (Prestressing Systems) and Clause 11 (Documentation & Records). L-715-80 [B.7-15] is deemed to meet the intent of Clause 9 (Metallic Parts). While the specifications used for the Pickering A/B construction meet the general intent of the N287.5-11 clauses mentioned above, the specification does not meet specific sub-clauses of some of these areas. In addition, Clause 8 (Non-metallic Liners) and Clause 10 (Anchorage Systems) do not appear to be addressed in the above references.

The standards that applied during original construction of Pickering NGS included requirements for tests and quality control procedures to ensure that the concrete used in the as-built structures met the original design requirements. As discussed above, the Pickering B ISR did not confirm that the requirements in effect during the construction of Pickering NGS comply with the requirements of CSA N287.5. Nevertheless, the original design requirements for Pickering 5-8 comply with the intent of N287.5-11. Per OPG Report NK30-REP-03680-00015 R000, "Pickering NGS-B Integrated Safety Review (ISR) - Final ISR Report" [B.7-17]:

> *New material was used in the construction of the PNGS B CCSs including the Pressure Relief Duct and the Vacuum Building common CCS. The concrete and steel materials were specified by qualified and experienced designers, some of whom were members of the technical committee that prepared the N287 series of standards, which were published, starting in 1976 (and later revised). These materials complied with the required code and have performed adequately since the time of construction in the 1970's…. As pointed out in OPG's response to CNSC's Comment as per NK30-CORR-00531-04973, "Pickering NGS-B Integrated Safety Review – Plant Design", September 23, 2008, Section B.6.5.1, the reinforced concrete is stronger than the strength required by modern codes… Therefore, the design of the CCSs meets modern performance requirements.*

Furthermore, ongoing confirmation that the Pickering NGS CCSs remain fit for service is demonstrated via the following:

- As required by N-PROG-MA-0017 R008 [B.7-18]:
  - Periodic inspection of containment system metallic and plastic components (including the containment pressure suppression systems) is performed in accordance with the requirements of CSA N285.5, "Periodic inspection of CANDU Nuclear Power Plant Containment Components". N-PROC-MA-0064 R005, "Administrative Requirements for the Periodic Inspection of Nuclear Power Plant Containment Components" [B.7-19], describes the administrative process and the roles of various organizations across OPG Nuclear involved in the execution of the Program in order to comply with the requirements of CSA N285.5.
  - Periodic examinations of in-service inspections and positive leakage rate testing of CCSs that are designated as class containment components are performed in accordance with the requirements of CSA N287.7, "In Service Examination and Testing Requirements for Concrete Containment Structures for CANDU Nuclear Power Plants". N-PROC-MA-0066 R005, "Administrative Requirements for In-Service Examination and Testing for Concrete Containment Structures" [B.7-20] describes the administrative process and the roles of various organizations across OPG Nuclear involved in the execution of N-PROG-MA-0017 R008 in order to comply with the requirements of CSA N287.7.
- With respect to aging management, N-PROG-MA-0017 R008 interfaces with the Integrated Aging Management Program to evaluate the condition of equipment (including containment structures) on an ongoing basis as defined by component programs, including management of equipment aging activities that: 1) identify aging

related degradation mechanisms, 2) define maintenance, inspection, test, and other activities, and 3) initiate preventive action to preclude component or system failure. A condition assessment process is used to evaluate the health of critical components and establish actions necessary to maintain long-term health. Condition assessments are prepared in accordance with N-PROC-MP-0060 R005 B, "Aging Management Process" [B.7-21] . Requirements for reporting (such as summarizing significant aging issues in component health reports) are identified in this procedure.

- Non-Destructive Examination (NDE) required for the periodic inspection of containment components is performed in accordance with N-STD-MA-0021 R001, "Non-Destructive Examination" [B.7-22] to ensure that these examinations meet code and jurisdictional requirements.

N-PROG-MP-0001 R014, "Engineering Change Control" [B.7-23] ensures that any future design changes made to the CCSs comply with modern applicable codes, standards, and regulations (including CSA N287.5) as applicable.

The above-mentioned Programs, Procedures and Standards are credited with the ability to detect and monitor any safety significant degradation mechanism and thus to provide assurance of continued fitness for service of the Pickering NGS CCSs.

Pickering Units 1,4

Pickering A Return to Service [B.7-24] did not review N287.5, as it "pertains mostly to operations aspects, or other aspects not having a direct or immediate effect on installed design features" [B.7-25]. Per the Pickering A Containment Design Requirements NA44-DR-63420-10001 R001 [B.7-26], CSA N287.5 is not listed as a "codes and standards (including addenda) applicable to the NPCS design."

The concrete structures at Pickering A were built and tested to meet the 1965 NBCC requirements [B.7-27] and associated CSA A23 Series Standards, supplemented by specific loading requirements and the requirements of Design Manuals (e.g., see [B.7-28], [B.7-29], [B.7-30], [B.7-31], [B.7-32]). As discussed above for Pickering Units 5-8, although Pickering A Return to Service did not demonstrate that the requirements in effect during construction comply with the requirements of CSA N287.5, ongoing confirmation that the Pickering NGS CCSs remain fit for service is demonstrated via periodic inspections and in-service testing. Further, the Engineering Change Control (ECC) process ensures that any future design changes made to the CCSs will comply with N287.5 as applicable.

Although N287.5 was not reviewed for either the Pickering B ISR or Pickering A Return to Service, an assessment was performed for Darlington and the programmatic aspects of the review are applicable to Pickering, as discussed below.

Darlington NGS

Appendix A of the Darlington ISR Code Review Report NK38-REP-03680-10060 R000 [B.7-33] notes gaps against ten clauses of CSA N287.5-93 [B.7-34]. Six of the gaps are due to use of alternate test requirements which could not be compared against original tests:

In summary, there is ample evidence that DN [Darlington Nuclear] was in compliance with the 1981 version of N287.5. However, without a detailed comparison of the specific test procedures which have evolved since 1981, or the results of those tests and possibly newer test methods not in existence in 1981, which would now be called for new NPP [Nuclear Power Plant] construction under the current standards, it must be concluded that based only on lack of review of inactive OPG records, this clause is considered to be a gap.

Four of the CSA N287.5-93 gaps were associated with new requirements that were not present in the 1981 version of the code. These gaps relate to new testing methods and frequencies for concrete materials, requirements for the properties and design proportions of concrete mix, concrete and grout testing methods and frequencies, and requirements on testing frequencies for sister splices, test beam specimens and vacuum boxes.

With respect to these ten gaps, NK38-REP-03680-10060 R000 states:

The report in Appendix A documents the review of CAN/CSA N287.5-93, "Examination and Testing Requirements for Concrete Containment Structures for CANDU Nuclear Power Plants". ISR Gaps were identified during the review and are documented in the report. During the ISR Gap resolution process, it was determined that none of the gaps identified in the report in Appendix A could be reclassified as compliant and no additional gaps were discovered. Therefore, the ISR Gaps remain as per the report.

OPG Report NK38-REP-03680-10104 R000, "Darlington NGS Integrated Safety Review (ISR) - Final ISR Report" [B.7-35] combined the ten N287.5-93 gaps into a single issue, stating:

Due to the lack of available compliance documentation, some of the testing requirements for testing concrete that were established by CAN/CSA-N287.5-M81 during DNGS construction have not been shown to satisfy CAN/CSA-N287.5-93. Some new requirements related to concrete testing introduced by CAN/CSA-N287.5-93 have not been incorporated in OPG governance.

NK38-REP-03680-10104 R000 classified the issue as an Acceptable Deviation, stating:

This issue applies to testing of concrete and grout during the initial construction, installation and fabrication of the Concrete Containment Structures. The CAN/CSA-N287.5-M81 standard that applied during original construction included requirements for tests and quality control procedures to ensure that the concrete used in the as-built structures met the original design requirements.

The current edition of the standard, CAN/CSA-N287.5-93, includes updated and additional concrete testing requirements, but due to the lack of available documentation it has not been demonstrated that the requirements previously in effect comply with these updated requirements. However, ongoing confirmation that the Concrete Containment Structures remain fit for service is demonstrated via the Periodic Inspection Program and In-service testing results.

The Periodic inspection of containment system components is performed in accordance with the requirements of CAN/CSA-N285.5-08 "Periodic inspection of CANDU Nuclear Power Plant containment components" and the In-service examinations and positive leakage rate testing of containment components are performed in accordance with the requirements of CAN/CSA-N287.7-08 "In Service Examination and Testing Requirements for Concrete Containment Structures for CANDU Nuclear Power Plants", as required by N-PROG-MA-0017 R006 "Component and Equipment Surveillance".

N-PROG-MP-0001 R009 "Engineering Change Control" ensures that any future design changes made to the Concrete Containment Structures comply with modern applicable codes, standards, and regulations (including CAN/CSA-N287.5-93).

No further action required.

ISR Issue reclassified as an Acceptable Deviation.

OPG Report NK38-REP-03680-10060-ADD-001 R000, "Addendum to the CAN/CSA N287.5-93 Code Review Report for Darlington ISR" [B.7-36] documents CNSC comments on the Darlington Final ISR Report [B.7-35] specific to N287.5, as well as OPG's responses and CNSC acceptance. No further action was required. OPG Report NK38-REP-03680-10201, "ISR Open Issues and Acceptable Deviations - Adequacy Review" [B.7-37] also concluded that the N287.5-93 gap was an Acceptable Deviation.

The Darlington argument above for classification of the N287.5 non-compliance as an Acceptable Deviation, which was agreed upon by the CNSC, is also applicable to Pickering NGS. Although gaps exist between the original design of Pickering and Darlington NGS CCSs and the current requirements of N287.5, in-service inspections are being conducted in accordance with the requirements of CSA N285.5 and N287.7 and the resultant inspection reports attest to the quality of the CCSs. Although Darlington was originally designed to the 1981 version of N287.5 and Pickering NGS was not, the fact remains that it is not practicable to make design changes to the CCSs without rebuilding them. Furthermore, the ECC process ensures that any design changes made to the Pickering CCSs comply with N287.5 going forward, as applicable.

With respect to changes made in the latest version of N287.5, a Code Refresh review was performed for CSA N287.5-11 and documented in NK38-REP-03680-10144 R000, "Code Refresh Review of CSA N287.5-2011 Examination and Testing Requirements for Concrete Containment Structures for CANDU Nuclear Power Plants" [B.7-38]. The review concluded:

The changes made in CSA N287.5-2011 relative to CSA N287.5-93 (R2004) are minor and mostly appear to be for clarification purposes. An additional section is added for documentation and records that do not have any technical requirements. The review of the changed clauses in this code refresh report confirms that OPG Nuclear governance continues to be in compliance with the requirements of CSA N287.5-2011…

In summary, the review did not identify any additional gaps relative to the requirements of CSA N287.5-2011. The review confirms OPG Nuclear governance is in *compliance with the changes in the requirements of CSA N287.5-2011 relative to CSA N287.5-93 (R2004).*

NK38-REP-03680-10144 R000 therefore confirms that no substantive (safety significant) changes were made in the 2011 version of N287.5 [B.7-3], and that OPG governance (which is applicable across OPG's nuclear fleet, including Pickering NGS) is in compliance with the changes in the requirements of CSA N287.5-11.

B.7.2.2 Application of Post PSR1 Reviews

Per the CSA N287.5-11 Impact Statement [B.7-3], the following is a summary of the significant changes from the previous edition of the standard:

- *Align the N287.5 standard with recently revised/updated CSA N series standards that are referenced throughout the document. The impact of aligning the format, definitions, and references in N287.5 to the other recently updated N287 series standards is intended to improve the clarity, and consistency of the standards scope and its linkage to other N287 standards. This will benefit future users of the codes, and has developed dialogue between the various subcommittees.*

- *Table 1 related to Concrete Materials has been aligned with Table 1 of N291. Current standards are references, and withdrawn standards are removed and replaced with relevant specifications. The update of N287.5 Table 1 was warranted to ensure that reference is made to current specifications. Its impact is intended to improve the quality of concrete materials examination and testing which meets current industry needs and technologies.*

- *Sections 6, 7 and 9 were modified based on suggestions by experts in examination and testing of reinforcement, pre-stressing, welding, respectively. The impact of incorporating input from expert professionals in the area of reinforcement, welding, and pre-stressing systems has impacted the code to better reflect updated examination and testing industry practices.*

The latest changes incorporated into CSA N287.5-11 were part of the clause-by-clause Code Refresh review performed for the Darlington ISR [B.7-37]. As discussed earlier, that review did not identify any additional gaps for N287.5-11 relative to the previous version of the Standard (CSA N287.5-93 [B.7-34]), and confirmed that OPG Nuclear governance (which is fleet wide and applicable to Pickering NGS) is in compliance with CSA N287.5-11. Nevertheless, CSA N287.5 was not assessed for Pickering NGS in PSR1, and the Darlington ISR conclusions are not fully applicable to Pickering PSR2. As discussed earlier, the original and subsequent revisions of CSA N287.5 were issued after completion of the design of Pickering A and B, and the CCSs were designed to meet the requirements of the National Building Code of Canada and applicable Design Manuals and Design Requirements at the time. The concrete used in the as-built Pickering NGS CCSs met the original design requirements, and the original Pickering construction included requirements for tests and quality control procedures which generally meet the intent of N287.5. However, evidence of full equivalency with N287.5 requirements is not available. As a result, this is a PSR2 gap for Pickering NGS (**PSR2 CSA N287.5 Gap #1**).

It is expected that this gap can be confirmed to be an Acceptable Deviation during the PSR2 Global Assessment process.

B.7.3 Compliance Summary for Pickering PSR2

There is one PSR2 CSA N287.5-11 gap which relates to Safety Factor 1 (Plant Design):

1. The Concrete Containment Structures (CCSs) at Pickering A and B were built and tested to meet the 1965 and 1970 National Building Code of Canada requirements, respectively, prior to the initial issuance of CSA N287.5. No assessments exist which demonstrate that the requirements in effect during construction of Pickering NGS CCSs comply with the requirements of CSA N287.5. Ongoing confirmation that the Pickering NGS CCSs remain fit for service is demonstrated via periodic and in-service inspections conducted in accordance with the requirements of CSA N285.5 and N287.7, and the resultant inspection reports attest to the quality of the design. In addition, the Engineering Change Control (ECC) process ensures that any design changes made to the Pickering CCSs will comply with N287.5 going forward, as applicable.

   The original Pickering construction included requirements for tests and quality control procedures which generally meet the intent of N287.5. Furthermore, retroactive application of N287.5 to the as-built design of CCSs cannot be practically achieved without rebuilding them. Nevertheless, there is a PSR2 gap for Pickering NGS given that compliance with the specific requirements of N287.5 has not been demonstrated.

B.8 CSA N290.0-11, "General Requirements for Safety Systems of Nuclear Power Plants"

B.8.1 Background

The following, paraphrased from the preface and introduction of CSA N290.0-11 [B.8-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of CSA N290.0 is to cover the design, qualification, installation, operation, maintenance, inspection, and documentation of the safety systems for a water-cooled nuclear power plant.*
>
> *N290.0 provides the general requirements for the safety systems and is a companion document of CSA N290.2 and N290.3, which outline specific requirements.*

The CSA N290.0 title refers to *Safety Systems*; however, it is only applicable to Special Safety Systems. In addition to being a companion document to N290.2 (Emergency Coolant Injection) and N290.3 (Containment), it is also a companion document to N290.1 (Shutdown Systems). Whereas CSA N290.1 was first issued in 1980, CSA N290.2 and N290.3 are far more recent and were initially issued in 2011, with the common requirements only in N290.0. These standards in conjunction with N290.0 have incorporated requirements from CNSC Regulatory Documents R-7 [B.8-2] and R-9 [B.8-3]. In addition, N290.1 has been revised to incorporate requirements from CNSC Regulatory Documents R-8 [B.8-4] and R-10 [B.8-6].

The relationship between and the PSR2 review approach for standards N290.0, N290.1, N290.2 and N290.3 are outlined here. The common generic requirements for the Special Safety Systems (previously addressed in earlier versions of N290.1, R-9 and R-7) were amalgamated into a companion document, CSA N290.0. The common requirements will be reviewed within the PSR2 N290.0 assessment. The system-specific requirements identified in N290.1, N290.2 and N290.3 will be reviewed within the PSR2 assessments for these standards. Any gaps identified as generic to the Special Safety Systems will be recorded as N290.0 gaps. If a gap is specific to only one of the Special Safety Systems, or system specific standard, it will be recorded as a gap against that standard (N290.1, N290.2, and N290.3) only.

All of N290.0-11 is directly relevant to Safety Factor 1 (Plant Design).

CSA N290.0 is identified in Appendix E.1 of the R04 Pickering Licence Conditions Handbook [B.8-7] as "Guidance or Criteria". Section 6.1, "Design Program" of the Licence Conditions Handbook [B.8-7] states that "Recommendations and guidance are found in… N290.0, which covers general requirements for safety systems". CSA N290.0-11 is the first edition of this standard.

The results of PSR1 CSA N290.0 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.8.2. As identified in Reference [B.8-8], the Pickering PSR2 review of CSA N290.0 is an Incremental Review. PSR2

Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.
- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.8.2 Compliance Assessment for Pickering PSR2

B.8.2.1 Application of PSR1 Reviews

The versions of N290.0 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

CSA N290.0-11 is the first edition of this Standard, published in October 2011. Therefore, there were no previous reviews of this standard conducted for Pickering. Many of the requirements contained in the standard are consistent with the content of the following CNSC Regulatory Documents:

- R-7, "Requirements for Containment Systems for CANDU Nuclear Power Plants" [B.8-2];
- R-8, "Requirements for Shutdown Systems for Nuclear Power Plants" [B.8-4];
- R-9, "Requirements for Emergency Core Cooling Systems for CANDU Nuclear Power Plants" [B.8-3]; and,
- R-10, "The Use of Two Shutdown Systems in Reactors" [B.8-5].

Code reviews of the CNSC regulatory documents R-7 [B.8-2], R-8 [B.8-4], and R-9 [B.8-3] were performed as part of the Pickering B ISR. The results of these reviews are included in the respective PSR2 CSA code reviews for CSA N290.1, CSA N290.2 and CSA N290.3, as well as CSA N290.0 for common requirements.

Darlington NGS

Following the issuance of CSA N290.0-11 [B.8-1] in October 2011, a clause-by-clause code review was conducted and documented in OPG Report NK38-REP-03680-10211 R000 [B.8-9].

The code review concluded that compliance was demonstrated for the majority of the requirements, except for twelve gaps against eight clauses. Ten were associated with approved design guide exceptions for Darlington special safety systems where separation and independence requirements could not be completely met. These are all related to Darlington-specific design features, and are not specifically applicable to Pickering. Therefore, these are not PSR2 gaps. The other two gaps are addressed below.

The first of these was a gap against clause 4.12.5, which states:

> *SSCs postulated to perform mitigating functions during and after exposure to harsh environmental conditions resulting from BDBAs [Beyond Design Basis Accidents] shall be assessed for their potential to perform their intended function under the expected harsh environmental conditions. Assessment of capability may be based on design specifications, environmental qualification testing, or other considerations.*

This was a gap for Darlington due to the Instrument Survivability Assessment for BDBAs not being complete at that time. This assessment has now been completed for all OPG stations and is documented in References [B.8-10] and [B.8-11].

The last gap was on clause 4.14.10 on human-machine interface requirements. The gap was a result of the lack of design standards related to Human Factors Engineering (HFE) or HFE activities being formally documented when the Darlington control centre was originally designed and constructed. This gap also applies to the Pickering Units 1,4 and 5-8 control rooms, due to the lack of formally documented HFE design standards at the time of the design and therefore is identified as **PSR2 CSA N290.0-11 Gap #1**. This gap is generic to each of the Special Safety Systems at both Pickering 5-8 and Pickering 1,4 and is, therefore, identified under N290.0.

B.8.2.2 Application of Post PSR1 Reviews

Section B.8.1 states that the PSR2 Basis Document [B.8-8] specifies the review of CSA N290.0-11 to be Incremental. However, more detail has been provided than is typical for an Incremental review in the assessment below, as the Darlington ISR contains minimal information specific to Pickering Special Safety Systems (SSSs). In the review below, the degree of conformance with clauses or groups of clauses in the Standard is demonstrated by supporting evidence stating whether the intent of the requirements stipulated in the requirement document is met.

CSA N290.0-11 Clause	PSR2 Review	Compliant or Gap
1. to 3.	Do not contain requirements.	N/A
4.1 General	The compliance of the Pickering SSSs to N286 standards is addressed in a separate PSR2 code review.	N/A
4.2 Plant States	This clause requires plant states be grouped into categories including Anticipated Operational Occurrences (AOOs), Design Basis Accidents (DBAs) and BDBAs. BDBAs are now considered in design; however, AOOs have not been identified or analyzed in the current Pickering Safety Reports. Hence, the requirements and	Gap

CSA N290.0-11 Clause	PSR2 Review	Compliant or Gap
	credits attributed to the Special Safety Systems for AOOs, if any, cannot be readily ascertained. This is identified as **PSR2 CSA N290.0-11 Gap #2.**	**PSR2 CSA N290.0-11 Gap #2**
4.3 System Operating States	Poised, unpoised, test and post-accident states are all included in SSS operating states defined in SSS Operating Manuals.	Compliant
4.4 General Design Requirements	N-STD-MP-0016, “Safe Operating Envelope” [B.8-12] identifies the requirement to establish safety limits for all SSSs, which are contained in the Operational Safety Requirements documents [B.8-13], [B.8-14], [B.8-15],[B.8-16], [B.8-17], [B.8-18]. All SSSs meet the requirements in this section and there are no PSR2 gaps.	Compliant
4.5.1 General Reliability Requirements	N-STD-RA-0033, "Reliability Monitoring and Reporting of Systems Important To Safety" [B.8-19], section 1.2.3, identifies the requirements for reliability targets for SSSs as follows: "For the Special Safety Systems the target shall be set equal to the licensing target. If site specific licensing targets are already established and accepted by the CNSC, then the licensee shall continue referring to these targets". Also, support systems are taken into account in the reliability analyses and probabilistic safety evaluations. All SSSs meet the requirements in this section and there are no PSR2 gaps.	Compliant
4.5.2 Reliability Analysis	Section 1.2 of N-STD-RA-0033, "Reliability Monitoring and Reporting of Systems Important To Safety" [B.8-19], identifies the requirements for the production of unavailability models for SSSs. These models use the test frequencies as defined in the Safety-Related Test Program. Models are updated to take into account current component failure rates and any other new information, e.g., new failure modes. All SSSs meet the requirements in this section and there are no PSR2 gaps.	Compliant
4.6 Separation and Independence	Requirements for Independence and Separation are contained in system Design Manuals and these requirements have been addressed in the SSS design. Engineering Change Control governance addresses these requirements for design changes. Also, the requirements for this set of clauses are contained in CNSC Regulatory Documents for each SSS: R-7, R-8 and R-9. The reviews	Compliant

CSA N290.0-11 Clause	PSR2 Review	Compliant or Gap
	of these documents for Pickering Units 1,4 [B.8-19] and Units 5-8 [B.8-21] demonstrated compliance with the requirements for separation and independence, with the following exceptions: • For the Units 1,4 Shutdown System, there are approved exceptions for Shutdown System A (SDSA) and Shutdown System Enhancement (SDSE) not being independent of each other. This is assessed in the PSR2 N290.1 assessment. • The Units 1,4 Emergency Coolant Injection (ECI) system is not independent from the moderator system since they share components in the design of ECIS recovery mode. This is assessed in the PSR2 N290.2 assessment. With respect to clause 4.6.2 (b), independence between SSS sub-systems is addressed by having separate sensitivity cases in the Safety Report analyzing impairments of sub-systems of the SSS.	
4.7 Single Failure Criteria	The requirements for this set of clauses are partially contained in CNSC Regulatory Documents clauses on Availability Requirements for each SSS: R-7, R-8 and R-9. The reviews of these documents for Pickering Units 1,4 [B.8-20] and Units 5-8 [B.8-21] demonstrated compliance with the requirement that SSS do not contain any active single components that can result in system unavailability. The only exception is the Unit 1,4 ECI system, which contains singleton components required to operate for the system to operate successfully. The PSR2 assessment of CSA N290.2-11, "Requirements for Emergency Core Cooling Systems of Nuclear Power Plants", reviews this PSR1 gap, which was assessed as an acceptable deviation, since all practical modifications were made to the Pickering Units 1,4 ECI system during Pickering A Return to Service and the system meets its unavailability target. Therefore this is not a PSR2 gap. In addition, to meet the other clauses in this section, all Units 1,4 and 5-8 SSSs consist of redundant components and channels (other than for the approved exceptions for Units 1,4 ECIS). This design permits testing, maintenance and other necessary activities to be completed without rendering the system unavailable. All SSSs meet the requirements in this section and there are no PSR2 gaps.	Compliant

CSA N290.0-11 Clause	PSR2 Review	Compliant or Gap
4.8 Fail Safe	The Pickering SSSs are generally designed to be fail safe as far as practical (as this clause permits), e.g., Instrument channels fail safe. There are exceptions to this, e.g., the Pickering containment Instrumented Pressure Relief Valves (IPRVs). The valves which operate the IPRVs are designed to fail closed on loss of support services, to prevent spuriously connecting the Vacuum Building to containment. Design exceptions of this type are acceptable by designing in sufficient redundancy and identifying component failures via Abnormal Condition annunciations. Failures of a single support system component do not result in unavailability of SSSs. This is addressed by supplying odd and even electrical power to redundant supplies, and by having redundant pumps and compressors supplying water and air respectively. All SSSs meet the requirements in this section and there are no PSR2 gaps.	Compliant
4.9 Safety Support Systems	Requirements for Safety Support Systems (electrical, water and air supplies) credited in the Safety Report to ensure the proper functioning of a SSS are contained in the Operational Safety Requirements (OSRs) (see the compliance discussion for clause 4.4). The PSR2 CSA N290.5 review of Electrical and Instrument Air systems did not contain any specific PSR2 Gaps related to support systems for SSSs. The SSSs are designed to not rely on operation of the turbine-generator or off-site electrical grid (per the compliance with R-7, R-8 and R-9), except for the High Pressure ECI (HPECI). The HPECI pumps are supplied by Class IV power supplied from the bulk electrical system and backed up by the Site Electrical System (SES), which supplies Class IV power from non-accident running units. In addition, the Pickering 1,4 HPECI injection valves are supplied power from the SES. The reliability of SES is such that the reliability of the HPECIS pumps meets requirements. However, in addition the SES supplied HPECI pumps and valves can be powered from diverse Class III Standby Generators supplies. Therefore, this is not a PSR2 gap. Lastly, any required ventilation provisions are provided for SSS design or its support systems, e.g., Class II power ventilation system.	Compliant

CSA N290.0-11 Clause	PSR2 Review	Compliant or Gap
	All SSSs meet the requirements in this section and there are no PSR2 gaps.	
4.10 Pressure-Retaining SSCs	The design requirements of the Pickering SSSs include meeting the requirements of CSA N285.0 and N287.7. Separate reviews of these Standards are being performed for PSR2.	Compliant
4.11.1 Selection of Instrumentation	The design of the Pickering SSSs includes all the Environmentally Qualified (EQ) instrumentation required for correct operation of the system as credited in the Safety Report. The requirements for this instrumentation are contained in the OSRs (see the compliance discussion for clause 4.4). Required surveillance and testing are documented in the OSRs. The Operating Manuals prescribe which instrumentation is to be used to confirm the system has operated as required after an accident.	Compliant
4.11.2 Instrumentation and Control	All of the Pickering SSSs are designed to initially operate automatically, such that operator action is not required for at least 15 minutes after an accident. The Main Control Room (MCR) contains the controls necessary for manual action/intervention. SSS instrumentation is included in the unavailability models and accuracy requirements are defined in Instrument Uncertainty Calculations (IUCs) referred to in the OSRs, and take into account applicable errors and uncertainties. The response times of critical instrument loops is also defined in the SSS OSRs and compliance is demonstrated during device calibrations or on-line testing. The requirements for testing in clause 4.11.2.10 are met for all SSS by preparing procedures that test and monitor SSS instrumentation as required by the OSR Compliance tables, referred to in the OSRs. All SSSs meet the requirements in this section and there are no PSR2 gaps.	Compliant
4.11.3 System Performance	The required process and SSS parameters are directly monitored in the MCR via redundant and reliable instrumentation, in station operating procedures to confirm the operability of the SSS, e.g., Heat Transport System pressure and temperature.	Compliant

CSA N290.0-11 Clause	PSR2 Review	Compliant or Gap
	Annunciations are provided in the MCR, meeting the requirements of clause 4.11.3.6, e.g. loss of ECI system pressure, loss of support systems. All SSSs meet the requirements in this section and there are no PSR2 gaps.	
4.12 Environmental Qualification	All Pickering SSSs meet the requirements of N-PROG-RA-0006, "Environmental Qualification" [B.8-22] to ensure credited equipment will operate in the conditions present following a design basis accident. Pickering Units 5-8 SSSs are designed to meet Seismic Design Basis Earthquake (DBE) or Site Design Earthquake (SDE) categories following a seismic event. Required Pickering Units 1,4 SSS equipment has been demonstrated to meet requirements of the Seismic Margin Assessment. N-PROG-MP-0008, "Integrated Aging Management" [B.8-23] defines the requirements for aging management of SSS components. Sub-clause 4.12.4 identifies that the impact of accident generated debris be addressed. This is specifically applicable to ECI recovery. The Units 1,4 and 5-8 ECI systems are equipped with ECIS recovery screens designed to accommodate debris and other contaminants generated after a DBA. All SSSs meet the requirements in this section and there are no PSR2 gaps.	Compliant
4.13 Dynamic Piping Effects	Requirements for dynamic piping effects, e.g., pipe whip, are contained in R-7, R-8 and R-9. The code reviews for these regulatory documents for Pickering Units 1,4 [B.8-20] and Units 5-8 [B.8-21] demonstrated compliance with this requirement except for an Acceptable Deviation raised for each of the Units 1,4 SSSs. There is an outstanding CANDU Safety Issue relevant to this clause [B.8-24]. There is a lack of a systematic assessment of high energy line break effects. Closure of this issue requires confirmation that the impacts of high energy line breaks have been captured in the design basis documents and the Safety Report. OPG has completed the High Energy Line Break Assessment (HELBA) for Pickering 5-8 and the Pickering 1,4 assessment is expected to be completed in 2017. Results to date, demonstrate that there would be no consequential damage caused by the rupture of high	Gap **PSR2 CSA N290.0-11 Gap #3**

CSA N290.0-11 Clause	PSR2 Review	Compliant or Gap
	energy pipes inside containment to safety related equipment, beyond that already accounted for in the Safety Reports. Since the Pickering 1,4 work has not been completed, this is identified as **<u>PSR2 CSA N290.0-11 Gap #3</u>**.	
4.14 Human Factors	Currently Human Factors Engineering (HFE) is considered for all design changes. The changes are managed through the Engineering Change Control Program and plant modifications follow the Modification Process. The Design Scoping Checklist [B.8-25] is a component of the modification process that identifies the level of HFE required. If the modification is judged to have an HFE impact, then the Human Factors Level of Activity Form [B.8-26] is completed to determine the scope of the HFE. A Human Factors Engineering Specialist must concur with the Human Factors Level of Activity. The modification may require the preparation of the Human Factors Engineering Plan or the Human Factors Worksheet [B.8-27]. These instructions and processes ensure that the human-system interface elements for the modification are addressed. The technical, design and operator reviews during and following the design process and via the Availability for Service (AFS) process, ensure the usability requirements will be achieved. The compliance discussion for clause 4.14.10 for Darlington states the following: *…While it is noted that the control centre for the plant was designed to the best standards of the day to provide "operator friendly" facilities, due to the lack of any design standards related to HFE in effect or HFE activities formally documented when the plant was originally designed and constructed, Darlington NGS is not considered to be in compliance with clause 7.21 (in CNSC Reg Doc RD-337).* The Pickering units have many years of safe operation and operating experience with special safety system monitoring, operation (including testing), maintenance and training (including simulator). Any potentially significant human interaction deficiencies due to the design would be identified during these activities and be addressed. Hence, the extent of application of human factors engineering in the original design is not expected to have an impact on nuclear safety relating to the SSSs. Ontario Hydro design practice in the original design phase recognized the need for focus on the operator interfaces in the control centres, and on recognition of the integrated whole of the control centre and the related	Gap **<u>PSR2 CSA N290.0-11 Gap #1</u>**

CSA N290.0-11 Clause	PSR2 Review	Compliant or Gap
	human-systems interfaces. However, as already identified in Section B.8.2.1 above, the Darlington gap is applicable to the design of the Pickering Units 1,4 and 5-8 control rooms and this is previously identified **PSR2 CSA N290.0-11 Gap #1**. Other clauses are addressed by the compliance discussion for clause 4.11.	
4.15 Fire Protection	A separate code review is being prepared for CSA N293.0 as part of PSR2. Also, Fire Hazard Assessments have been performed to ensure SSSs meet requirements for safe shutdown of the reactor after a fire. All SSSs meet the requirements in this section and there are no PSR2 gaps.	Compliant
4.16 System Health Monitoring	N-PROC-MA-0024,” System Performance Monitoring” defines the requirements for monitoring the SSSs and meets the requirements of clause 4.16.	Compliant
4.17 Operability	Station Operating Policies and Principles (OP&Ps) and other operating procedures define when a SSS can be removed from service. Abnormal Incidents Manuals (AIMs) define the required actions to take if a system is found to be inoperable. The Pickering SSSs are designed such that no manual action is required in the MCR for 15 minutes after a DBA and 30 minutes for required field actions. Shielding requirements to gain access to equipment after a DBA are contained in the Design Requirements documents for ECI and Containment systems. The compliance assessment for clause 4.11.2 applies to other clauses in this section (4.17.7 & 4.17.8). All SSSs meet the requirements in this section and there are no PSR2 gaps.	Compliant
4.18 Maintainability	The compliance assessment for clause 4.7 applies to the majority of clauses in this section addressing design features to optimize maintenance practices, e.g., ensuring maintenance can be performed without making the system unavailable. Isolation devices are in the design of SSSs to permit maintenance.	Compliant

CSA N290.0-11 Clause	PSR2 Review	Compliant or Gap
	All SSSs meet the requirements in this section and there are no PSR2 gaps.	
4.19 Maintenance Program	N-PROG-MA-0004, "Conduct of Maintenance" [B.8-28] defines the maintenance requirements for plant SSCs, including SSS components and includes the Preventative Maintenance program [B.8-29]. Surveillance of equipment condition is performed via System Monitoring (per clause 4.16) and Components and Equipment surveillance per N-PROG-MA-0017 [B.8-30]. To perform required maintenance, operating procedures direct that the component be placed in a safe state, where possible. All SSSs meet the requirements in this section and there are no PSR2 gaps.	Compliant
4.20.1 Testing - General	N-STD-OP-0018, "Operability Testing of Safety Related Systems" [B.8-31] defines the methods/processes for SSS testing. Section 1.5.1 states: *Operability Tests shall be conducted at frequencies required for meeting station's Predicted Future Unavailability (PFU) targets and frequencies shall be determined by Reactor Safety Support in accordance with approved procedures.* This requirement ensures that the SSSs will meet the required reliability targets. The other clauses of 4.20.1 are met by having N-STD-0018 and Pickering Units 1,4 and 5-8 Safety Related System Tests (SRSTs) in place.	Compliant
4.20.2 Functional Testing	N-STD-OP-0018, "Operability Testing of Safety Related Systems" [B.8-31] defines the methods/processes for SSS testing. SSS tests are in place with acceptance criteria consistent with the requirements of the OSRs.	Compliant
4.20.3 Post-Maintenance Testing	Station OP&Ps require testing be performed following SSS component maintenance. Requirements for post-maintenance testing are specified in maintenance instructions and procedures. Operational testing to confirm availability upon completion of maintenance is done in accordance with operating procedures and manuals.	Compliant

CSA N290.0-11 Clause	PSR2 Review	Compliant or Gap
4.20.4 Commissioning	Commissioning Tests were performed for all Pickering SSSs prior to unit start-up per the requirements of this section.	Compliant
4.21 Sharing Within a Unit	The Pickering SSSs generally do not share components (including instrumentation) with a process system. There are exceptions, all of which satisfy the design considerations of this clause. For example: Units 1,4 ECIS shares moderator system components, e.g., the main moderator pumps, which is identified and assessed as part of the CSA N290.2 PSR2 review for Pickering Units 1,4. Containment System Air Cooling Units (ACUs) perform both a process and safety function, but the requirements of this clause are met, e.g., the essential safety functions are unaffected by the initiation of the Loss of Coolant Accident (LOCA) event. All SSSs meet the requirements in this section and there are no PSR2 gaps.	Compliant
4.22 Sharing Between Units	The SSS OSRs are based on the limiting DBA and credited components are environmentally qualified per the requirements in clause 4.12. Common cause events were considered in the design of the Pickering Units 5-8 SSSs by adopting the two Group philosophy. Group 2 systems have been qualified to ensure they can operate after a common cause event, e.g., a seismic event or main steam line failure. For Units 1,4, capabilities have been assessed to ensure safe shutdown following a seismic event (per the Seismic Margin Assessment). For main steam line failures in the powerhouse, an emergency heat sink, Emergency Boiler Water Supply (EBWS) and alternate electrical supply to critical loads (Inter-Station Transfer Bus (ISTB)) were added to Pickering Units 1,4 to provide comparable capabilities to Units 5-8. The sharing of systems between units has been assessed for internal and external common cause events and the nuclear safety consequences demonstrated to be acceptable. All SSSs meet the requirements in this section and there are no PSR2 gaps.	Compliant

CSA N290.0-11 Clause	PSR2 Review	Compliant or Gap
4.23 Documentation	The following SSS documents fulfill the requirements of this section: Design Manuals Design Descriptions Design Requirements Operational Safety Requirements (OSRs) Operating Manuals	Compliant

B.8.3 Compliance Summary for Pickering PSR2

There are three PSR2 N290.0-11 gaps which relate to Safety Factor 1 (Plant Design):

1. The Darlington Integrated Safety Review (ISR) identified a gap against Clause 4.14.10 of N290.0-11 as a result of the lack of design standards related to Human Factors Engineering (HFE) or HFE activities being formally documented when the control rooms were originally designed and constructed. Pickering NGS has many years of successful Special Safety System (SSS) operation and the absence of formal HFE in the original design is not expected to have any nuclear safety significance relating to SSSs. However, the Darlington gap is also applicable to Pickering NGS and is therefore identified as a PSR2 gap.

2. Clause 4.2 of N290.0-11 requires that Plant States be grouped into several categories, including Anticipated Operational Occurrences (AOOs). This is consistent with clauses of REGDOC-2.4.1 and REGDOC-2.5.2 related to identification and classification of initiating events. Since AOOs have not been identified and analyzed in the current Pickering Safety Reports, the requirements and credits attributed to the Special Safety Systems for AOOs, if any, cannot be readily ascertained. This issue has therefore been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation.

3. OPG is currently in the process of completing the High Energy Line Break Assessment (HELBA) for Pickering NGS. Preliminary results show that there would be no consequential damage caused by the rupture of high energy pipes inside containment to safety related equipment, beyond that already accounted for in the Safety Reports. The final HELBA reports for Pickering Units 5-8 have been completed, while Pickering Units 1,4 are expected to be completed in 2017. Since this work has not been completed for Pickering 1,4, this is identified as a PSR2 gap.

B.9 CSA N290.1-13, "Requirements for the Shutdown Systems of Nuclear Power Plants"

B.9.1 Background

The following, paraphrased from the preface and introduction of CSA N290.1-13 [B.9-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of CSA N290.1 is to act as a general standard for reactor shutdown systems of nuclear power plants. It establishes the design, procurement, installation, commissioning, operation, testing, and maintenance requirements of the shutdown system(s) to terminate the fission chain reaction in the event of an accident.*
>
> *CSA N290.1 applies to existing and new water-cooled nuclear power plants, both CANDU and non-CANDU. CSA N290.1 incorporates the relevant requirements of the CNSC regulatory documents R-8, "Requirements for Shutdown Systems for CANDU Nuclear Power Plants, and R-10, "The Use of Two Shutdown Systems in Reactors".*

All of N290.1-13 is directly relevant to Safety Factor 1 (Plant Design).

Compliance with N290.1 is not currently a licence requirement for Pickering NGS (PROL 48.02/2018) and is not referenced in the Pickering Licence Condition Handbook [B.9-2].

CSA N290.1-13 is the second edition of CSA N290.1. It supersedes the previous edition: N290.1-80 published in December 1980 under the title "Requirements for the Shutdown Systems of CANDU Nuclear Power Plants" [B.9-3]. The CSA Impact Statement notification for CSA N290.1-13 [B.9-4] provides a "Summary of Significant Changes from the Previous Edition", which identifies changes to the Standard that are discussed in Section B.9.2 below.

The relationship between and the PSR2 review approach for standards N290.0, N290.1, N290.2 and N290.3 are outlined here. The common generic requirements for the Special Safety Systems (previously addressed in earlier versions of N290.1, R-9 and R-7) were amalgamated into a companion document, CSA N290.0. The common requirements will be reviewed within the PSR2 N290.0 assessment. The system-specific requirements identified in N290.1, N290.2 and N290.3 will be reviewed within the PSR2 assessments for these standards. Any gaps identified as generic to the Special Safety Systems will be recorded as N290.0 gaps. If a gap is specific to only one of the Special Safety Systems, or system specific standard, it will be recorded as a gap against that standard (N290.1, N290.2, and N290.3) only.

The results of PSR1 N290.1 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.9.2. As identified in Reference [B.9-5], the Pickering PSR2 review of CSA N290.1-13 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.

- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.9.2 Compliance Assessment for Pickering PSR2

B.9.2.1 Application of PSR1 Reviews

The versions of N290.1 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

A clause-by clause review of the Pickering Units 5-8 Shutdown Systems (SDSs) against CSA N290.1-80 [B.9-3] was documented in NK30-REP-03680-00001 R000 [B.9-6].

This review concluded that with the exception of the 14 documentation deficiencies that posed gaps, the Shutdown Systems were found to be in direct compliance with the design requirements stated in CSA-N290.1-80. Actions were completed to address these document deficiencies. The following revised documents were issued: NK30-DR-63730-10002 [B.9-7], NK30-DR-63720-10001 [B.9-8], and NK30-DR-31730-10001 [B.9-9].

In addition Reference [B.9-6] identified eight Acceptable Deviations. Their relevance to extended Pickering operation is reviewed below. The eight Acceptable Deviations are:

- Clause 4.4.1.2 identifies a requirement that during the design phase, a target unavailability of $1x10^{-4}$ yrs/yr be used. This is not a requirement in N290.1-13, so is not relevant to PSR2.

- Clause 4.4.1.3 identifies a requirement that the design target for spurious operation of a shutdown system be 10^{-1} yrs/yr or less. This is related to clause 4.2.2 in N290.1-13, which requires a spurious trip frequency target be established. The justification provided for the acceptable deviation for PSR1 remains valid for PSR2 and is not impacted by operation beyond 2020.

- Clause 4.4.1.4 identifies a requirement that in the design phase, the system unavailability be calculated on the basis of the most demanding accidents and shall be based on main trip parameters only. This is related to clause 4.2.1.2 in N290.1-13 and to reliability requirements contained in CSA Standard N290.0-11, "General Requirements for Safety Systems for Nuclear Power Plants" [B.9-10]. These requirements are met by performing unavailability calculations for the Pickering Units 1,4 and 5-8 SDSs per the regulatory requirements in RD-98. Therefore this is not a PSR2 issue.

- Clause 4.4.1.5 identifies requirements for single failures, e.g., failure of any single instrumentation device shall not render the system unavailable or should be fail-safe. This requirement is now contained in CSA N290.0, Clause 4.7 and there are no gaps relating to the Shutdown Systems.

- Clause 4.4.2.5 requires that the grouping of components of a channel be adequate to allow commissioning, operations and maintenance without affecting the operation of other channels. The Pickering Units 1,4 and 5-8 SDSs designs meet this requirement by having redundant trip channels and procedures are in place for channelized maintenance and operational testing. Therefore this is not a PSR2 issue.

- Clause 4.4.14.1 on Quality of Equipment identifies basic requirements, e.g., of proven design, have predictable failure modes and last the life of the plant. It is related to requirement 4.7.1 in N290.1-13. These requirements have been demonstrated to be satisfied given the reliable operation of the Shutdown Systems and, therefore, is not an issue for PSR2.

- Clauses 6.1.1 and 6.2.2 on design documentation, require the requirements of the standard be contained in the design documentation and identify specific information to be included. These are not requirements in N290.1-13, so these clauses are not relevant to PSR2.

In addition to the review of N290.1, a review of the Shutdown Systems was performed against regulatory document R-8 "Requirements for Shutdown Systems for Nuclear Power Plants" [B.9-11]. This review was documented in NK30-REP-03680-00001 R000 [B.9-6]. This review will be used in the compliance discussion of the latest N290.1 version. This report concluded that other than one gap, the Pickering Units 5-8 Shutdown Systems comply with the requirements of R-8. The one gap was raised since the design documentation did not contain the requirements of clause 3.6.2, which states the following:

> *Manual actuation may be considered acceptable in place of one of the automatic parameters provided it is shown to the satisfaction of the AECB[10] that all of the following requirements are met:*
>
> > *(a) There is instrumentation designed to give the operator clear and unambiguous indication of the need to actuate the shutdown system.*
> >
> > *(b) The reliability of such instrumentation is commensurate with the requirements for availability of the shutdown system as specified in Section 3.4. If indication of only a single parameter is required, the instrumentation shall be part of the shutdown system…*

Requirement (a) is a Safety Analysis requirement which is met for all special safety systems. Requirement (b) is satisfied by including the required instrumentation in SDS unavailability

[10] Now the CNSC.

models. Given this, there is no gap associated with this clause and, therefore, the Pickering Units 5-8 Shutdown Systems comply with the requirements of R-8.

<u>Pickering Units 1,4</u>

As part of Pickering A Return to Service (PARTS), code reviews were conducted. The main submission for PARTS [B.9-12] committed to perform a review of N290.1-80 [B.9-3], which was the active version at that time. This review was completed in AECL Report, "Review of Pickering A Design Against Current Codes and Standards" [B.9-13]. This report reviewed the level of compliance of the Shutdown System (including both Shutdown System A (SDSA) and Shutdown System Enhancement (SDSE) logic).

This report provides a high level review of the degree that the Shutdown System complies with N290.1-80 through the addition of the new SDSE.

The SDSE for Units 1,4 was not intended to adopt all the CSA requirements since: (1) SDSE is an enhancement to an existing system, and (2) there are practical design constraints inherent in back-fitting changes to an existing shutdown system and reactor structure [B.9-13].

The design principles in the N290.1-80 requirements that could not be fully complied with were requirements for independent shutdown systems with conceptually different reactivity components, diverse trip parameters, and trip parameter displays in a Secondary Control Area.

Practical limitations on the SDSE design arose due to the layout of existing equipment, space availability, and the presence of high radiation fields in certain areas. Prior to developing the Nuclear Safety Design Requirements (NSDRs) for SDSE, these issues were discussed extensively with the CNSC. As a result of these discussions, the conceptual design and NSDRs of the Pickering Units 1,4 SDSE were finalized and accepted by the CNSC. The NSDRs also contain a requirement that for any deviations from requirements, the SDSE design must be shown to meet the intent of the requirement. This information is documented in the NSDR as an exception. This formal process ensured that the SDSE design met the intent of N290.1-80.

Reference [B.9-13] concludes that:

> *The intended overall performance of the Pickering 'A' Shutdown Systems will not be significantly affected by the identified deviations from full compliance with CSA N290.1-80. The enhanced shutdown system at Pickering 'A' provides further defence-in-depth through increased shutdown system reliability, trip coverage, reactivity depth, and protection against common-mode cross-link effects, such that the overall shutdown system effectiveness approaches that normally attributed to reactors having two completely separate and independent shutdown systems.*

There were six clauses that were not satisfied by the SDSE design and based on the above were classified as Acceptable Deviations. The reasons for not fully complying with the CSA requirements and the implications on shutdown system performance were assessed as being acceptable in [B.9-13] and were accepted by the CNSC. The basis for the acceptability of the exceptions continues to be applicable and is not impacted by operation beyond 2020. Note, the requirements for shutdown system separation and independence have been moved from CSA

N290.1 to N290.0 Clause 4.6 when the 2013 version of N290.1 was issued. However, the rationale and acceptance for classifying this issue as an Acceptable Deviation in PSR1 remains valid for PSR2.

In addition to the above noted deviations related to SDSE, Reference [B.9-13] identified seven other Acceptable Deviations. Their relevance to extended Pickering operation is reviewed below. The seven Acceptable Deviations are:

- Clause 4.4.3.3 requires that where instrumentation does not fail-safe on a loss of power, the loss of power condition shall be annunciated. The review concluded that there were sufficient alternate indications, including panel checks, such that these failures do not detract from the SDS availability. Note, this requirement has been moved to CSA N290.0-11, "General Requirements for the Safety Systems of Nuclear Power Plants" [B.9-10], Clause 4.8. The rationale for this acceptable deviation classification is applicable for PSR2 and is not impacted by operation beyond 2020.

- Clause 4.4.8.1 prescribes requirements for display of trip variables and their trip setpoints in the Main Control Room (MCR)/secondary control areas. The code review states:

  > *Continuous displays of the trip variables are provided in the MCR for both SDSA and SDSE. However, displays of trip setpoints are provided only for SDSE and some SDSA trips that use indicating alarm units on the control room panels. Given that the setpoints are generally fixed values, their display is not a significant benefit to safety.*

  This acceptable deviation is not impacted by operation beyond 2020.

- Clause 4.4.9 related to testing states:

  Dedicated on-line test facilities shall be provided to confirm the correct operation of the Shutdown System, including:

  a) Confirmation of the actual trip set point values;

  b) The response times of the critical elements of the system;

  c) The independence of redundant portions of the system;

  d) The necessary system availability requirements.

  On-line testing of critical parameter response times is not performed for all SDS components at Pickering. In lieu of this, bench testing is performed. The Safe Operating Envelope Compliance Tables for Pickering Units 1,4 [B.9-14] and Pickering Units 5-8 [B.9-15] demonstrate this. The updated version of N290.1 does not contain the requirement that response times be measured on-line, so both Units 1,4 and 5-8 SDSs comply with requirements and, therefore, this is not a PSR2 gap.

- Clause 4.4.9.6 contains specific requirements for testing of SDS sensors and how it should be performed, e.g., by manipulating the input variable until it reaches the setpoint. This specific requirement is no longer in N290.1-13 Section 4.5 on in-service testing and therefore is not relevant to PSR2.

- Clause 4.4.14.2 on Quality of Equipment requires manufacture and fabrication of equipment meet the requirements of the CSA Z299 series of standards. SDSA did not meet this standard as it was not available at the time of the original design. Subsequent modifications complied with this requirement. Pickering Units 5-8 SDSs meet this requirement. This remains not safety significant and is not a PSR2 issue.

- Clause 4.4.16.4 states that where a number of channels of one system are in close proximity, colour coding to differentiate between channels is the preferred identification method. This is not a mandatory requirement and not a PSR2 issue.

- Clause 5.1 requires the design, procurement and installation of SDSs meet the N286.0 series of standards. SDSA does not reference these standards as they were not available at the time of the original design. Subsequent modifications complied with this requirement. Pickering Units 5-8 SDSs meet this requirement. This remains not safety significant and is not a PSR2 issue.

In addition to the review of N290.1, a review of the Shutdown System was performed against regulatory document R-8 "Requirements for Shutdown Systems for Nuclear Power Plants" [B.9-11]. This review will be used in the compliance discussion of the latest N290.1 version. This review documented in [B.9-13] demonstrated that other than for the approved exceptions for the SDSE design described above, one gap and one acceptable deviation, the Pickering Units 1,4 Shutdown System complied with R-8.

The gap relates to Safety Report trip coverage assessments not directly addressing a loss of service water/loss of moderator cooling. However, since that time these events have been addressed in Appendix 9 of the Units 1,4 and 5-8 Safety Reports [B.9-16] and [B.9-17].

The one Acceptable Deviation was on the requirements for the design of SDSA in consideration of dynamic effects or jet forces. The applicable clause is no longer contained in N290.1 and an equivalent clause is contained in N290.0. The PSR2 review of CSA N290.0-11, "General Requirements for Safety Systems of Nuclear Power Plants", Clause 4.13 assesses the impact on all Special Safety Systems and identifies a Gap. However, because it is a generic gap, it is assigned as a PSR2 CSA N290.0-11 Gap.

Darlington NGS

The original code review of the Darlington ISR, as documented in OPG Report NK38-REP-03680-10011 R000 [B.9-18], was performed against CSA N290.1-80 [B.9-3]. In general it was found that the Darlington design of the Shutdown Systems met the requirements of N290.1-80. NK38-REP-03680-10011 does identify the following three gaps:

1. Common manufacturers are used for the SDS1 and SDS2 in-core flux detectors, in-core flux detector amplifiers, ion chamber amplifiers and computer termination modules.

Therefore, this resulted in a gap against clause 4.1.3.2. However, appropriate design and production separation was maintained during the manufacturing process.

Pickering Units 1,4 used the same manufacturer for SDSA and SDSE in-core flux detectors. However, compensating measures were taken such as: they were procured from different manufacturing plants and there is a slight difference in diameter between the Shutdown Systems. Pickering Units 5-8 complies with this clause [B.9-6]. In addition, this clause is no longer contained in N290.1-13. Therefore, this issue is not a PSR2 gap.

2. Response times of all critical components are not confirmed during on-line tests. Shutoff Rods and Liquid Injection Shutdown System valve timing are confirmed on-line and loop response testing of parameters is available on-line (Clause 4.4.9.2). However, component response time is confirmed as part of commissioning and post-maintenance testing. This above approach to response time testing was accepted by CNSC.

   This issue was later re-classified in Appendix B of NK38-REP-03680-10011 [B.9-18] as not a gap. Appendix B cites a procedure that had previously been prepared for Darlington, NK38-PROC-68000-002, "Requirements for Darlington NGS SDS1 & 2 – Safety Related Systems Tests" [B.9-19], which outlines how Darlington complies with the requirements for SDS critical parameter response times. Part of the basis for this is that Darlington utilizes digital components in its SDS trip logic, which do not degrade over time.

   This issue has already been addressed above for Pickering Units 1,4 and Units 5-8 and is not a PSR2 gap.

3. A minor documentation gap existed only for SDS1 Design Requirement documentation under Clause 4.4.15.4 dealing with qualification program testing. The clause is explicitly stated in the Design Requirements for SDS2 but not in the Design Requirements for SDS1 even though both systems are environmentally qualified. Both Pickering Units 1,4 and 5-8 comply with the requirements of this clause per the above code reviews and, therefore, this is not relevant to PSR2.

Following the issuance of CSA N290.1-13 [B.9-1] in December 2013, a code refresh review was conducted and documented in OPG Report NK38-REP-03680-10155 R000 [B.9-20]. A clause-by-clause review was done given the nature of the revisions made to the standard. NK38-REP-03680-10155 identifies that Darlington is in compliance with the requirements of CSA-N290.1-13 and no new gaps were identified. The changes made between version N290.1-80 and the new version N290.1-13 are discussed in the next section.

B.9.2.2 Application of Post PSR1 Reviews

As discussed above, CSA N290.1 has been updated since the last code reviews were performed for Pickering. It was updated to N290.1-13 [B.9-1] in 2013 from the original version N290.1-80 [B.9-3]. There were a number of changes made in the update of the code. The code was re-organized, the requirements made more precise and modified to be technology neutral. Of the changes listed in the CSA Impact Statement for the issue of N290.1-13 [B.9-4], only three potentially have some nuclear safety impact. These are:

a) It incorporates regulatory documents R-8 and R-10 (preserves the important requirements).

b) It has been aligned with regulatory document RD-337 (incorporation of design extension conditions and new build requirements).

c) Requirements have been made more precise (specific changes are not listed in the Impact Statement).

Since the changes referred to in items (a) and (c) are not specific, the new version was reviewed to identify any significant issues that are relevant to PSR2.

From an overall perspective, since the design of the Darlington Shutdown Systems complies with this new version of N290.1, it is expected that the same is the case for Pickering Units 5-8 SDS1 and SDS2. The designs are very similar and have the same design requirements with respect to: their function, two group philosophy, independence and separation, channelization, diversity, trip logic design, and having a fail-safe design, etc.

This is also predominantly the case for Pickering Units 1,4 Shutdown System, including SDSA and SDSE logic (with the exceptions discussed in section B.9.2, which have been assessed as being acceptable).

In addition, the following information and analyses demonstrate that the Units 1,4 and 5-8 Shutdown Systems meet nuclear safety objectives and licensing requirements:

- Performance requirements to ensure credits in the Safety Report are satisfied and Safety Report objectives are met, are contained in the Operational Safety Requirements (OSR) for Pickering Units 1,4 and 5-8 [B.9-21] and [B.9-22].

- The Probabilistic Safety Assessments have demonstrated that public safety goals have been met with the design performance of the Shutdown Systems.

- Per Regulatory Document RD/GD-98 [B.9-23], unavailability analyses are completed that demonstrate that reliability requirements are met for the Shutdown Systems.

- Environmental and seismic qualification requirements are in place to ensure the required performance following applicable design basis accidents.

- Compliance with regulatory document R-8 [B.9-11] has been demonstrated for both Pickering Units 5-8 and Pickering Units 1,4 with any exceptions being acceptable, as described above.

The presence of all the above information, provides assurance that the N290.1-13 requirements are met for Pickering Units 1,4 and Units 5-8 at a high level.

For additional assurance, the requirements of N290.1-13 and N290.1-80 were compared to determine if there were any safety significant changes where Pickering SDSs may not meet the intent of the revision (not including those described above for Pickering Units 1,4 Shutdown System that have approved exceptions). The majority of clauses in N290.1-80 are covered in N290.1-13. The following clauses fall into the category described above and are the clauses with potential safety significant intent changes:

- Clause 4.3.3.4 states:

  Trip set points shall be selected to provide sufficient allowance between the set points and the corresponding safety limits to account for uncertainties. The uncertainties include but are not limited to:…

  This clause is new in N290.1-13. It is satisfied by completion of Instrument Uncertainties Calculations for Pickering Units 1,4 and 5-8. These are referenced in the Operational Safety Requirements documents [B.9-21] and [B.9-22].

- Clause 4.4.2 on MCR displays states:

  For certain trip parameters, such as those that originate from in-core flux detectors, display of margins to trip should be provided in the main control room.

  The MCR design provides for a display of margin to trip for in-core flux detectors for Pickering Units 1,4 SDSA and SDSE. The same applies to Pickering Units 5-8 SDS1 and SDS2. Therefore this clause is met.

- Clause 4.6 on Cyber Security

  This clause is new and identifies considerations for cyber security. OPG has a program in place to ensure cyber security requirements are in place as per OPG Procedure, N-PROC-MP-0103, "Security for Real-Time Process Computing Systems" [B.9-24]. Therefore this clause is met.

In addition to the above there is one new requirement relating to new plant designs. This is,

- Clause 4.1.8.2 requires remote tripping and monitoring capability to be available for both Shutdown Systems in a secondary control room. Pickering 5-8 has tripping capability for both Shutdown Systems in the main control room. Pickering 1,4 has SDSA and SDSE tripping capability from the main control room.

  Pickering 5-8 has SDS2 tripping capability in the Unit Emergency Control Centres (UECCs). Pickering 1,4 has remote SDSE tripping capability in the SDSE instrument room. The purpose of this requirement is to ensure that probability of failure to shut down is sufficiently low for events that result in the main control room becoming unavailable (typically for common mode events). Failure to shut down the reactor using manual trips for common mode events is unlikely to be a significant contributor to plant risk; however, this has not been confirmed. Therefore, the absence of remote SDS tripping and monitoring capability for Pickering 5-8 SDS1 and Pickering 1,4 SDSA is **PSR2 CSA N290.1-13 Gap #1**.

Given the previous PSR1 reviews and additional reviews of specific clauses, Pickering is largely compliant with the significant safety clauses in the standard, with the exception of the gap identified.

B.9.3 Compliance Summary for Pickering PSR2

There is one PSR2 CSA N290.1-13 gap which relates to Safety Factor 1 (Plant Design):

1. Clause 4.1.8.2 of CSA N290.1-13 is for a new plant and requires remote tripping and monitoring capability for both Shutdown Systems. Pickering Units 1,4 only have one Shutdown System with tripping capability from separate logic (SDSA and SDSE). Remote tripping capability is available for Pickering 5-8 SDS2 and Pickering 1,4 SDSE. However, Pickering Units 5-8 and 1,4 do not have remote tripping and monitoring capability for SDS1 or SDSA respectively. Therefore, this has been identified as a PSR2 gap.

B.10 CSA N290.2-11, "Requirements for Emergency Core Cooling Systems of Nuclear Power Plants"

B.10.1 Background

The following, paraphrased from the preface and scope of CSA N290.2 [B.10-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of CSA N290.2 is to ensure the emergency core cooling system meets its primary purpose, which is to transfer heat from the reactor core following a loss of reactor coolant that exceeds the makeup capability of process systems.*
>
> *CSA N290.2 sets the requirements for the design, qualification, installation, operation, maintenance, inspection, and documentation of the emergency core cooling system for a water-cooled nuclear power plant. CSA N290.2 also applies to all support systems required to ensure that the ECC [Emergency Core Cooling] system is able to maintain adequate heat transfer for as long as necessary to maintain the release of radioactive material within reference dose limits by limiting fuel failure.*

All of N290.2-11 is directly relevant to Safety Factor 1 (Plant Design).

CSA N290.2 is identified in Appendix E.1 of the R04 Pickering Licence Conditions Handbook [B.10-2] as "Guidance or Criteria". Section 6.1, "Design Program" of [B.10-2] states that "Recommendations and guidance are found in… N290.2, which covers emergency core cooling."

CSA N290.2-11 is the first edition of the standard. It replaces Regulatory Document, R-9: "Requirements for Emergency Core Cooling Systems for CANDU Nuclear Power Plants" [B.10-3] and is largely based on it. Previous code reviews for Pickering were performed against R-9.

The relationship between and the PSR2 review approach for standards N290.0, N290.1, N290.2 and N290.3 are outlined here. The common generic requirements for the Special Safety Systems (previously addressed in earlier versions of N290.1, R-9 and R-7) were amalgamated into a companion document, CSA N290.0. The common requirements will be reviewed within the PSR2 N290.0 assessment. The system-specific requirements identified in N290.1, N290.2 and N290.3 will be reviewed within the PSR2 assessments for these standards. Any gaps identified as generic to the Special Safety Systems will be recorded as N290.0 gaps. If a gap is specific to only one of the Special Safety Systems, or system specific standard, it will be recorded as a gap against that standard (N290.1, N290.2, and N290.3) only.

The results of PSR1 CSA N290.2 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.10.2. As identified in Reference [B.10-4], the Pickering PSR2 review of CSA N290.2-11 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.

- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.10.2 Compliance Assessment for Pickering PSR2

B.10.2.1 Application of PSR1 Reviews

CSA N290.2-11 is the first edition of the standard. Therefore it was not subject to previous reviews conducted for Pickering. A code review was conducted for Darlington against CSA N290.2 and is addressed below. CSA N290.2 replaces Regulatory Document, R-9: "Requirements for Emergency Core Cooling Systems for CANDU Nuclear Power Plants" [B.10-3] and is largely based on it. Previous code reviews for Pickering were performed against R-9.

The versions of N290.0 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

CSA N290.2 was not in effect at the time of the Pickering B ISR code reviews. A clause-by clause review of the compliance of the Pickering Units 5-8 Emergency Coolant Injection System (ECIS) against R-9 (CSA N290.2 predecessor) was documented in NK30-REP-03680-00001 R000 [B.10-5].

With the exception of three gaps associated with document discrepancies, the ECIS design was found to comply with the requirements of R-9. The three gaps were:

1. ECIS design requirements shall be based on the assumption that the least effective of the shutdown systems has operated successfully (clause 2.3). This requirement is contained in clause 5.2.1.2 of N290.2-11 and, therefore, this is still applicable.

2. ECIS cooling requirements must be capable of addressing a Design Basis Accident coincident with an impairment of containment (clause 3.2). This requirement is not contained in N290.2-11 and therefore this gap is not applicable to PSR2.

3. Discrepancies between ECI Heat Transport low pressure signal setpoint between the Design Requirements and the OSR (Clause 3.4.9).

These three gaps have been addressed by revising the Pickering Units 5-8 ECIS Design Requirements documentation [B.10-6] to include the two requirements and to address the discrepancy. However, the requirement in clause 5.2.1.2 of N290.2-11 is not achievable for Pickering Units 1,4 ECIS because there is only one Shutdown System [B.10-7]. Therefore, this is identified as **PSR2 CSA N290.2-11 Gap #1**.

One Acceptable Deviation was raised in the assessment, regarding clause 3.4.9 on the use of manual intervention. There are certain conditions when High Pressure (HP) injection may no longer be essential after a loss of coolant accident and thus can be terminated by the Operator. For example, following successful initial HP injection, once the HTS has been filled and temperatures lowered, HP injection can be terminated and Low Pressure (LP) pumps will automatically be started. The required actions to make this operating mode transition are controlled and documented in system Operating Manuals. Therefore, this is not a safety significant issue for PSR2.

Pickering Units 1,4

As part of Pickering A Return to Service (PARTS), code reviews were conducted. CSA N290.2 did not exist at that time. The main submission for PARTS [B.10-8] committed to perform a review of Regulatory Document R-9 (CSA N290.2 predecessor). This review was completed in AECL Report, "Review of Pickering A Design Against Current Codes and Standards" [B.10-9].

The review identified the following seven gaps:

1. Clause 2.2 (b) on the requirement that support systems shall be considered as safety support equipment and meet all the requirements of R-9. There was only one requirement in clause 3.4.5 where compliance could not be shown. A loss or high temperature of Low Pressure Service Water (LPSW) will affect the moderator heat exchangers and moderator room Air Cooling Units (ACUs), incapacitating ECIS recovery. To address this issue a design change was made prior to units restarting, to provide a back-up source of cooling water to the moderator HXs. Therefore there is no PSR2 gap.

2. Clause 3.4.1 requires the ECI system to satisfy availability requirements. ECIS could not be shown to meet the legacy R-9 [B.10-3] unavailability target of $1x10^{-3}$ yrs/yr for all scenarios. Design changes recommended in the "Core Damage Frequency Reduction Study – Pickering NGS A Risk Assessment (PARA) Review" [B.10-10] were made to improve ECI recovery availability. CSA N290.2-11 does not specify an ECI system reliability target. Instead, there is now a generic special safety system reliability requirement in CSA N290.0-11, Clause 4.5.1. Limits are established as part of CNSC RD/GD-98 compliance and the licencing target for ECI is $2x10^{-3}$ yrs/yr [B.10-11], which has been demonstrated to be met per [B.10-11]. Therefore, this is not a PSR2 gap.

3. Clause 3.4.3 requires the design to have redundancy such that a single failure cannot result in a loss of system capability. Thirteen instances of single failures existed in the design, of which five were being addressed by design changes. Reference [B.10-9] provided justification for addressing those five as they resulted in the greatest reduction in core damage frequency. The single failures not addressed were either of low probability or there would be high radiological exposure (person-rem) to make changes. This rationale remains valid and does not introduce a PSR2 gap.

4. Clause 3.4.5 requires that as far as practicable, all ECIS equipment shall be designed such that its most probable failure modes will not result in a reduction in safety. Changes were made to address this issue, as identified in Reference [B.10-10]. Therefore there is no PSR2 gap.

5. Clause 3.5.2 requires that as far as practicable, the ECIS shall be independent from all process systems. The Pickering 1,4 ECI system utilizes the moderator system in its low pressure recovery mode. However, based on the improvements made to the design and changes proposed in Reference [B.10-10], the degree of commonality between the moderator system and ECI recovery has been reduced. Therefore this requirement was met to the degree practicable and was an Acceptable Deviation for PARTS PSR1. This rationale remains valid and there is no PSR2 gap.

6. Clause 3.5.4 requires that if ECIS sub-systems are considered to be independent for the purpose of safety analysis, principles for separation and independence of each sub-system shall be prepared and approved by the regulator. It was recommended to review the Safety Report to identify credits for independence between sub-systems and document the basis for the assumed independence. This R-9 clause is included in N290.0-11, Clause 4.6.2 (b) [B.10-12] rather than in N290.2-11. Assessment of that clause is contained in the PSR2 assessment of CSA N290.0 and it did not identify any gaps relating to sub-system independence, with the exception of the dependence on the moderator system, which has already been addressed in Item 5 above.

7. Clause 3.11 on seismic requirements specifies requirements for equipment to function following a site design earthquake. To achieve full compliance with this requirement, the moderator pump motors need to be seismically qualified. To comply with this requirement all components in the ECI recovery flowpath have been seismically assessed [B.10-13]. Therefore there is no PSR2 gap associated with this issue.

The review also identified one Acceptable Deviation on the requirements for the design of ECIS in consideration of dynamic effects or jet forces. This requirement is included in N290.0-11, Clause 4.13 rather than in N290.2. Further, this issue is a PSR2 Gap common to all Special Safety Systems and is, therefore, addressed in the PSR2 assessment of CSA N290.0.

Darlington NGS

The code review of the Darlington ISR, as documented in OPG Report NK38-REP-03680-10004 R000 [B.10-14], was performed against R-9. It was found that the Darlington design of the ECI system meets the requirements of Regulatory Document R-9[11].

Following the issuance of CSA N290.2-11 [B.10-1] in October 2011, a Code Refresh review was conducted and documented in OPG Report NK38-REP-03680-10212 R000 [B.10-15]. A clause-by-clause review was done given this was the first edition of the standard and due to the significant differences between R-9 and N290.2. For example, all of the requirements common to all special safety systems that were contained in R-9 for ECIS, are now contained in CSA N290.0-11, "General Requirements for the Safety Systems of Nuclear Power Plants" [B.10-12].

---

[11] A gap on clause 3.5.4 was initially identified in the report, but was later modified to be compliant in Appendix B.

In addition, Reference [B.10-15] states that: "N290.2 is devoted to modern day requirements specific to ECC performance and provides a greater level of detail than R-9." This will be considered in Section B.10.2.2 on the application of Post-PSR1 reviews.

NK38-REP-03680-10212 [B.10-15] identifies that Darlington is in compliance with the requirements of CSA-N290.2-11 and no gaps were identified.

B.10.2.2 Application of Post PSR1 Reviews

The CSA N290.2-11 Impact Statement [B.10-16] provides a summary of significant features of the new standard. Of the features described, the following are considered safety significant for the purposes of PSR2:

1. *The standard reflects current Canadian regulatory requirements.*
2. *The standard includes requirements for debris interceptors and controls to minimize fouling of interceptors.*

In addition, the Darlington Code Refresh [B.10-15] summarized that N290.2 is devoted to modern day requirements specific to Emergency Core Cooling performance and provides a greater level of detail than R-9.

With respect to the standard reflecting current regulatory requirements, this is not a PSR2 issue. It was confirmed that both Pickering Units 1,4 and 5-8 comply with the requirements of R-9, or that any exceptions for Units 1,4 are acceptable [B.10-9], [B.10-5].

<u>Requirements for Debris Interceptors or Strainers</u>

Clause 5.14 contains requirements for debris interceptors. Clause 5.14.1 states:

> *Existing plants shall demonstrate that their existing debris interceptors meet minimum allowable performance standards. Clauses 5.14.2 through 5.14.16 shall apply to new builds.*

Clause 5.14.1 is satisfied for Units 1,4 by the following:

- The ECIS design contains strainers in the flowpath to the suction of the moderator pumps, which assure that minimum pump Net Positive Suction Head (NPSH) requirements are satisfied during ECIS recovery operation.
- Significant work has been performed to formulate a conservative methodology used to determine the debris quantities to be used for assessing strainer design adequacy [B.10-17].
- Sections 5.2, A.1.3, A.4.1, C.4.3.7, D.4.3.3 of the Pickering Units 1,4 Operational Safety Requirements (OSR) [B.10-18] discuss and provide the allowable performance

standards for the ECIS strainers and identify the required actions if standards (limits) are not met.

Clause 5.14.1 is satisfied for Units 5-8 by the following:

- The ECIS design contains strainers in the flowpath to the suction of the ECI recovery pumps, which assure that minimum pump NPSH requirements are satisfied during ECIS recovery operation.

- Significant work has been performed to formulate a conservative methodology used to determine the debris quantities to be used for assessing strainer design adequacy [B.10-17].

- Sections 5.2, A.1.3, A.4.7, A.4.8, Table A.4 and D.4.3.3 of the Pickering Units 5-8 OSR [B.10-19] discuss and provide the allowable performance standards for the ECIS strainers and identify the required actions if standards (limits) are not met.

The other aspect of this first edition of N290.2 identified in Reference [B.10-15] is that requirements have been made more precise. These changes were not specified in the CSA Impact Statement. The approach taken was to review the new version to identify any significant issues that could impact Pickering's PSR2 compliance given the following context.

From an overall perspective, since the Darlington ECI System design complies with N290.2, it is expected that the same is the case for Pickering Units 5-8. The designs are similar and have the same design requirements with respect to: their function, two group philosophy, independence and separation, channelization, diversity and being fail-safe, etc. The Units 1,4 ECI design contains a significant difference in that portions of the moderator system are used for ECIS recovery mode. This difference was previously assessed in the Pickering A Return to Service R-9 review [B.10-9] and demonstrated to not pose a significant safety impact.

In addition the following information and analyses demonstrate that the Units 1,4 and 5-8 ECI systems meet nuclear safety objectives and licensing requirements:

- Performance requirements to ensure credits in the Safety Report are satisfied, are contained in the OSR for Pickering Units 1,4 and 5-8 [B.10-18] and [B.10-19].

- The Probabilistic Safety Assessment has demonstrated that public safety goals have been met with the design performance of the Pickering ECI systems.

- Per Regulatory Document RD/GD-98 [B.10-20], unavailability analyses are completed that demonstrate that reliability requirements are met for the ECI systems.

- Also, environmental and seismic qualification requirements are in place to ensure the required performance following applicable design basis accidents.

The presence of all the above information provides assurance that the N290.2-11 requirements are met for Pickering at a high level. For additional assurance, the requirements of N290.2-11 were reviewed to determine if there were any new requirements, or clauses containing more precise wording than contained in R-9, or differences in the Darlington design compared to Pickering, that could challenge Pickering's PSR2 compliance with the new standard.

As a result of this review, the following clause was identified, which requires review:

- Clause 5.7 on Chemistry, Water Quality and Inventory Management is new and contains requirements that are potentially safety significant. The following sub-clause requires review:

  Clause 5.7.1 (c) states:

  > *Water chemistry, specifically pH and oxygen levels, shall be controlled to prevent: interactions of chemicals that might lead to fouling (e.g., plugging of instrument tubing, loading of debris interceptors, poison precipitation).*

  For Pickering Units 1,4 safety limits are in place for the pH level and concentration of hydrazine as specified in Table A.1 of the OSR [B.10-18]. For Pickering Unit 5-8, similar safety limits are contained in the Table A.1 of the Pickering Units 5-8 OSR [B.10-19]. Chemistry Control procedures ensure these safety limits are met during operation, per Chemical Control Procedure, "Emergency Coolant Injection Unit 058", NK30-CCP-33350-00001 [B.10-21]. This satisfies this clause.

  The following clauses related to 5.7.1 (c) are also satisfied with the same compliance basis: 5.7.2.1, 5.7.2.3, 5.7.3.1, 5.7.4.1 and 5.7.4.3.

Clauses 5.12 and 5.13 on Venting and Draining and Leakage Collection respectively, are new clauses not contained in R-9. However, they do not contain safety significant requirements and both Pickering Units 1,4 and 5-8 have design features similar to Darlington. Other clauses are either not safety significant, or Pickering Units 5-8 and 1,4 have design features similar to Darlington.

As noted above, CSA N290.2-11 has requirements for debris interceptors (strainers) that are specific to new plants in Clauses 5.14.2 through 5.14.16. Several of these clauses (e.g., 5.14.9, 5.4.13, 5.14.15, 5.14.16) relate to controls of materials and compounds used inside containment in order to minimize the potential for consequential strainer plugging. OPG initiated and completed additional assurance work for both Pickering 5-8 and Pickering 1,4 to address these issues under CNSC Generic Action Item (GAI) 06G01 *Emergency Core Cooling Strainer Deposits.*

A detailed assessment of the potential sources of strainer debris and contaminants is documented in [B.10-22] for Pickering 5-8. This assessment demonstrated that there was sufficient margin to ensure post-accident ECI recovery strainer effectiveness. A similar assessment was performed for Pickering 1,4 in [B.10-23]; however, this review identified vulnerabilities to strainer failure due to the incremental debris loading. In order to restore margin, a project was initiated to modify the Pickering 1,4 ECI recovery strainer design and to install new strainer modules in Units 1 and 4. This installation is now complete. Therefore, the above demonstrates that Pickering is compliant with the requirements for new plant debris interceptors.

However, there is one ancillary requirement relating to debris interceptors for new plants with which Pickering does not comply. This relates to Clause 5.14.11 which requires instrumentation to be available to monitor post-accident effectiveness and to determine the extent of plugging of the interceptor. While relative health of a strainer can be inferred by a combination of ECI recovery pump performance and reactor building water level, there is no direct correlation between these conditions and debris loading available. This is, therefore, **PSR2 CSA N290.2-11 Gap #2** and is applicable to both Pickering 5-8 and 1,4.

Given the above review of specific clauses, Pickering 5-8 complies with the significant safety clauses in the standard. For Pickering 1,4 there was one gap identified. Additionally, there is one gap relating to specific requirements for a new plant design which is common to all Pickering Units.

B.10.3 Compliance Summary for Pickering PSR2

There are two PSR2 CSA N290.2-11 gaps which relate to Safety Factor 1 (Plant Design):

1. Clause 5.2.1.2 of CSA N290.2-11 requires that Emergency Coolant Injection System (ECIS) design requirements be based on the assumption that the least effective of the Shutdown Systems has operated successfully. The Pickering Units 5-8 Safety Report analysis does address this requirement and the requirement is also contained in the Pickering Units 5-8 Design Requirements. However, this requirement cannot be met for Pickering Units 1,4 since there is only one Shutdown System (albeit with tripping capability from separate SDSA and SDSE logic). Therefore, this has been identified as a PSR2 gap.

2. Clause 5.14.11 of CSA N290.2-11 requires instrumentation to be available to monitor post-accident effectiveness and to determine the extent of plugging of Emergency Coolant Injection System (ECIS) debris interceptors (strainers). While relative health of a strainer can be inferred by a combination of ECIS recovery pump performance and reactor building water level, there is no direct correlation between these conditions and debris loading available. Therefore, this has been identified as a PSR2 gap (which is applicable to both Pickering Units 5-8 and 1,4).

B.11 CSA N290.3-11, "Requirements for the Containment System of Nuclear Power Plants"

B.11.1 Background

The following, paraphrased from the preface and scope of CSA N290.3-11 [B.11-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of CSA N290.3 is to ensure the containment system fulfills the following safety functions:*
>
> - *Controls and minimizes radioactive releases for normal operation, AOOs [Anticipated Operational Occurrences], and DBAs [Design Basis Accidents];*
> - *Considers BDBAs [Beyond Design Basis Accidents], including severe accident conditions; and*
> - *Minimizes the impact of radiological exposure to plant personnel from within the containment boundary.*
>
> *CSA N290.3 sets the requirements for the design, instrumentation, shielding, support systems, operations, and maintenance of the containment system. In addition, it sets the design requirements for containment subsystems.*

All of N290.3-11 is directly relevant to Safety Factor 1 (Plant Design).

CSA N290.3 is identified in Appendix E.1 of the R04 Pickering Licence Conditions Handbook [B.11-2] as "Guidance or Criteria". Section 6.1, "Design Program" of [B.11-2] states that "Recommendations and guidance are found in… N290.3, which covers containment systems."

CSA N290.3-11 is the first edition of the standard. It replaces Regulatory Document, R-7: "Requirements for Containment Systems for CANDU Nuclear Power Plants" [B.11-3] and is largely based on it. Previous code reviews for Pickering were performed against R-7.

The relationship between and the PSR2 review approach for standards N290.0, N290.1, N290.2 and N290.3 are outlined here. The common generic requirements for the Special Safety Systems (previously addressed in earlier versions of N290.1, R-9 and R-7) were amalgamated into a companion document, CSA N290.0. The common requirements will be reviewed within the PSR2 N290.0 assessment. The system-specific requirements identified in N290.1, N290.2 and N290.3 will be reviewed within the PSR2 assessments for these standards. Any gaps identified as generic to the Special Safety Systems will be recorded as N290.0 gaps. If a gap is specific to only one of the Special Safety Systems, or system specific standard, it will be recorded as a gap against that standard (N290.1, N290.2, and N290.3) only.

The results of PSR1 CSA N290.3 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.11.2. As identified in Reference [B.11-4], the Pickering PSR2 review of CSA N290.3-11 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.
- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.11.2 Compliance Assessment for Pickering PSR2

B.11.2.1 Application of PSR1 Reviews

CSA N290.3-11 is the first edition of the standard. Therefore, it was not subject to previous reviews conducted for Pickering. A code review was conducted for Darlington on CSA N290.3-11 and is addressed below. CSA N290.3 replaces Regulatory Document, R-7: "Requirements for Containment Systems for CANDU Nuclear Power Plants" [B.11-3] and is largely based on it. Previous code reviews for Pickering were performed against R-7.

The versions of CSA N290.3 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

CSA N290.3 was not in effect at the time of the Pickering Units 5-8 code reviews. A clause-by clause review of the compliance of the Pickering Units 5-8 Containment System against R-7 (predecessor to N290.3) was documented in NK30-REP-03680-00001 [B.11-5].

With the exception of five gaps, the Containment design was found to comply with the requirements of R-7. The five gaps were:

1. Analysis could not be found to demonstrate that containment can adequately withstand overpressures resulting from complete failure of dousing in combination with other initiating events. This addressed three of the discrepancies against clauses 3.4.1, 3.4.3 and 3.4.4. This requirement does not exist in the revised N290.3-11, therefore this is not a PSR2 gap.

2. Regarding clause 3.7.4, the design documentation does not include the requirement that the containment system is not dependent on power supplies from the turbine generators associated with any reactor unit within that containment system. This is a documentation issue only. The containment systems at Pickering Units 1,4 and Units 5-8 do not rely on Class IV power to fulfill any of their safety functions. This requirement is addressed in N290.0-11, Clause 4.9 rather than in N290.3-11. This issue has no safety significance and is not a PSR2 gap against CSA N290.0.

3. There is a gap on clause 3.9 which refers to Appendix A clause A.2.2 (c). It pertains to containment penetrations consisting of one closed isolation valve for lines of 50 mm or less, which are normally closed to the containment atmosphere and connected to an easily defined closed system outside containment. The requirement is that they be part of the containment envelope and be constructed to the requirements of the ASME Code (Section III, Class 2). The code review identifies this gap as a documentation issue since the requirement is not contained in the Design Requirements document. This requirement is still contained in N290.3-11. OPG committed to assess the level of compliance with Appendix 2.2 and revise the required design documentation [B.11-6]. The gap was later closed on the basis that "a review of our design requirements and applications has concluded that PNGS-B Containment appurtenance isolation valves are in compliance with R-7 Clause A2.2(c)".

In addition the following six Acceptable Deviations (ADs) were raised in the assessment:

1. Clause 3.4.2 identifies that the negative design pressure of containment must not be greater than that predicted in the Safety Report for a set of postulated events with failure of dousing. It is not necessary to evaluate event combinations involving failure of dousing for negative containment design pressure impacts, because these event combinations result in higher rather than lower containment pressure. Therefore, this is not a PSR2 gap.

2. Clause 3.8.3 requires design principles for separation of redundant instrument channels be prepared and be approved by the regulator. These requirements relating to separation are not included in N290.3-11, rather they have been incorporated into clauses under 4.6 of CSA N290.0-11, "General Requirements for the Safety Systems of Nuclear Power Plants" [B.11-7]. However, there is no specific requirement for regulatory approval of the separation principles, therefore, there is no gap relating to this issue for PSR2.

3. Clause 3.8.4 requires that if containment sub-systems are considered to be independent for the purpose of safety analysis, principles for separation and independence of each sub-system shall be prepared and approved by the regulator. This requirement is not contained in N290.3-11, but the principles of separation and independence for safety analysis have been incorporated into Clause 4.6.2 of CSA N290.0-11. However, regulatory approval is not required in CSA N290.0, therefore, there is no gap relating to this issue for PSR2.

4. Clause 3.11.2 requires that a report be prepared demonstrating the adequacy of shielding provisions to ensure required operator access after an accident. The reports have been prepared for both Units 1,4 and 5-8 as required by this clause but they have not been referenced in the containment design documentation. This issue is a documentation issue only and not safety significant. Clause 11.1 in updated N290.3-11 requires adequate shielding provisions be present, but does not contain a requirement for the information to be referenced in the design documentation, therefore this is not considered a PSR2 gap.

5. Clause 3.13.1 requires that the application for a construction approval identify any aspects of the design that fail to comply with applicable codes and standards in: CSA N285 and N287. Any applicable codes and standards relevant to containment design are assessed in PSR2.

6. Clause 3.13.2 requires a list of codes and standards to be applied to the containment system be prepared and have approval by the CNSC prior to construction approval. This clause is not included in N290.3 but has been incorporated in the clauses under 4.23 of N290.0. Codes and standards applicable to Containment are referenced in the design documentation; however, there is no longer an explicit requirement for regulatory approval in the standard. Therefore, this is not considered a PSR2 gap.

Pickering Units 1,4

As part of Pickering A Return to Service (PARTS), code reviews were conducted. N290.3 did not exist at that time. The main submission for PARTS [B.11-8] committed to perform a review of Regulatory Document R-7. This review was completed in AECL Report, "Review of Pickering A Design Against Current Codes and Standards" [B.11-9].

The review identified the following gap:

Clause 3.8.4 requires that if containment sub-systems are considered to be independent for the purpose of safety analysis, principles for separation and independence of each sub-system shall be prepared and approved by the regulator. This requirement does not exist in N290.3-11 but it has been included in N290.0, Clause 4.6.2 [B.11-7]. However, regulatory approval is not required in CSA N290.0. Therefore, there is no gap relating to this issue for PSR2.

The review also identified the following five ADs:

1. Clause 3.6.2 requires that dynamic effects or jet forces caused by the event cannot result in impairment of the containment system.

   This clause is no longer contained in N290.3 and an equivalent clause is contained in N290.0, which has been reviewed separately for PSR2.

2. Clause 3.7.1 requires that containment system unavailability be less than $1x10^{-3}$ yrs/yr and that systems supporting containment operation be commensurate with this requirement.

   At the time of the code review the predicted unavailability was greater than this target. The latest available Pickering Units 1,4 Annual Reliability Report [B.11-10] documents that the predicted future unavailability of the containment system is less than $0.74 x10^{-3}$ yrs/yr. In addition many support systems are included in the list of systems important to safety, e.g., Class III power, and are shown to meet their unavailability targets as well. Therefore, this AD is no longer applicable and compliance with this clause can now be demonstrated. Therefore this is not a PSR2 gap.

3. Clause 3.10.3 requires that the design of the plant be such that non-essential sources of compressed air be isolated.

   Installation of the rupture panel system on Units 1,4 has resulted in a reduction of non-accident unit compressed air in-leakage. With this modification the Safety Report demonstrates that the post-accident containment pressurization times exceed 48 hrs, which meets requirements set out by the CNSC.

   For Pickering Units 5-8, the Reactor Building (RB) bulkheads would be isolated post-accident to minimize compressed air in-leakage into containment after an accident. As a result the Safety Report demonstrates that the post-accident containment pressurization times exceed 48 hours for DBAs in Units 5-8 as well.

   Therefore this is not a PSR2 gap.

4. Clause 5.1.1 requires that negative pressure proof pressure tests be performed.

   This requirement is not met because the containment envelope was not tested to the lowest predicted negative pressure following an accident. However, the negative design pressure is limited due to the multi-unit design of Pickering Containment and the code review demonstrates that leakage is not expected to be significant at these pressures. This rationale remains valid for PSR2 and the issue is not a gap.

5. Clause 2 in Appendix A requires containment extensions meet ASME code Class 2 requirements.

   R-7 was not in place during the design of Pickering and the design of containment penetrations/extensions did not meet Class 2 requirements. The code review provides the justification for this AD being acceptable, as meeting this requirement was not practicable, and the Pickering Units 1,4 design has been demonstrated to be reliable over 40 years of testing and operation. This rationale remains valid for PSR2 and the issue is not a PSR2 gap.

Darlington NGS

The original code review of the Darlington ISR, as documented in OPG Report NK38-REP-03680-10002 R000 [B.11-11], was performed against R-7 [B.11-3]. It was found that the Darlington design of the containment system meets the requirements of regulatory document R-7, with one exception relating to locking closed single isolation valves. CSA N290.3 only contains requirements relating to locking closed containment boundary valves in Annex B, which is applicable to new build applications only. This is addressed under the requirements for new plants below.

Following the issuance of CSA N290.3-11 [B.11-1] in October 2011, a Code Refresh review was conducted and documented in OPG Report NK38-REP-03680-10213 R000 [B.11-12]. A clause-by-clause review was done given this was the first edition of the standard and due to the differences between R-7 and N290.3. For example, all of the requirements common to all special safety systems that were contained in R-7, are now contained in CSA N290.0-11, "General Requirements for the Safety Systems of Nuclear Power Plants" [B.11-7].

The Darlington Code Refresh review of N290.3-11 documented in NK38-REP-03680-10213 [B.11-12] resulted in 27 gaps. Of these gaps, eight are related to mitigating the impacts of Beyond Design Basis Accidents (BDBAs) and Severe Accidents, which are new requirements not contained in R-7, eight of the gaps apply to new plant design while the remaining eleven gaps cover various topics.

The Darlington BDBA gaps relate to the assurance of containment integrity, radionuclide management system (RMS) and energy management system (EMS). Because of differences between the Darlington and Pickering unit designs, containment designs and BDBA progression, Pickering is utilizing a different approach to address BDBA response (systems and mitigation strategies). The Pickering Filtered Air Discharge System (FADS) is used as the BDBA RMS while FADS in conjunction with Reactor Building Air Cooling Units (ACUs) provides the EMS function [B.11-13].

Completion of Phase 2 Emergency Mitigating Equipment (EME) implementation is required to provide further enhancement for BDBA response providing AC power for FADS and Reactor Building ACUs and their services. Since Phase 2 EME implementation is not complete, this is **PSR2 CSA N290.3-11 Gap #1** relating to enhancements to the containment RMS and EMS for BDBAs.

The CSA N290.3-11 new build clauses and gaps are addressed in a subsection further below, while the specific Darlington gaps that need to be considered for applicability to Pickering PSR2 are discussed immediately below:

1. Clause 6.4, Note (2) requires the selection of materials used inside containment shall consider coverings, coatings and cladding. The code review refers to a gap against clause 8.6.11 against previous regulatory document RD-337 [B.11-14]. This was classified as an AD for Darlington. Although there were no specifications for coatings in the original Darlington design basis, the impact of this issue has been addressed in safety analysis and in the design of the Emergency Coolant Injection System (ECIS) recovery strainer. No other safety issues were raised. This disposition also applies to Pickering. For example, the modified ECIS recovery strainer analysis considers the liberation of chemicals and other materials that could result in a pressure drop across the strainers that could affect pump operation (also refer to PSR2 review of N290.2-11). Therefore, this is not a PSR2 gap.

2. Clause 7.4 requires that leakage limits be defined for both gas and liquid phases. The gap exists since the Safety Report and Darlington Operational Safety Requirements (OSRs) have no separate leakage limits for liquids through containment penetrations. The Pickering Units 1,4 and Units 5-8 OSRs do not contain these limits either. However, per Darlington Issue D613 [B.11-15], this had a low safety significance and was determined to be an acceptable deviation. This was because Derived Release Limits have been established and are complied with for liquid releases during normal operation; bounding safety analysis is done for failures outside of containment and failures that result in some containment by-pass (e.g., Steam Generator consequential

leaks); and means are available to recover and mitigate waterborne leakage. Because of similarities in the safety analysis assumptions and methodology between Pickering and Darlington, the issue resolution is also applicable to Pickering. In addition, Pickering reactor building airlock solid seals on the 254' elevation provide an additional barrier to liquid release post-accident. Therefore, this is not a PSR2 gap.

3. Clause 7.6 requires that for BDBAs, the containment boundary leakage rate shall be maintained below the maximum allowable long enough to allow for implementation of off-site emergency procedures. For Pickering, FADS procedures for BDBA have been developed such that operation with containment above atmospheric pressure is possible. Allowing more containment pressurization time provides more time to implement off-site response. The assessments of accident scenarios as part of the Environmental Assessment for Pickering B Refurbishment Life Extension [B.11-16] confirmed there to be more than 24 hours available for off-site actions for the representative BDBA accident category (Ex-Plant Release Category 5 (EPRC5)). Therefore, this is not a PSR2 gap.

4. Clause 9.2.1.1 requires that all containment penetrations be designed to be leak tight. The design of Darlington penetrations meets the intent of this requirement as per Nuclear Safety Design Guide NK38-DG-03650.7 [B.11-18] Section 3.5 which identifies penetration seal requirements. The intent of the clause was met, but the explicit requirement to design a leak tight penetration was considered a gap.

   For Pickering, this is an implicit requirement, since the entire containment boundary, including penetrations is designed to be leak tight to the degree practicable. This is demonstrated in successful periodic reactor building and vacuum building leakage rate tests. The results of these tests demonstrate there is significant margin between the measured leakage rate and Safety Report assumptions. The trend of measured leakage rates demonstrates that margin will be maintained for operation beyond 2020. Therefore this is not a PSR2 gap.

5. Clause 9.5 on combustible gas management requires recombiners. Passive Autocatalytic Recombiners (PARs) were installed at Darlington meeting this clause. Since the issue of the code review, installation of PARs has been completed on all OPG units, therefore this gap no longer exists.

6. Clause 9.5.1 requires management of combustible gases be provided to control concentrations to preclude destructive combustion modes. Management of combustible gases is addressed in the Safety Report, but the code review identifies a gap related to RD-337 [B.11-14] clause 8.6.10. Since the issue of the code review, installation of PARs has been completed on all OPG units, therefore this gap no longer exists.

7. Clause 9.5.6 requires that in the case of a severe accident, emergency venting of containment shall consider the build-up of combustible gases to minimize injury to plant personnel and damage to SSCs from deflagration. Darlington addressed this in Issue D607 [B.11-17] citing implementation of Severe Accident Management Guidelines (SAMG) and plant modifications with minimizing the risk of hydrogen deflagration and addressing this gap.

For Pickering, design differences from Darlington require a different approach. Emergency venting with FADS and hydrogen mitigation are addressed in the SAMG. The applicable SAMG documents require that negative implications of any SAMG actions be assessed including unacceptable impacts on credited SSCs and personnel safety.

8. Clause 10.2.2 requires a list of containment conditions that need to be monitored for BDBAs be developed. Containment parameters to be monitored for a severe accident are developed in SAMG documentation. This was a gap for Darlington as an equivalent list had not been developed for BDBAs.

   This is not a gap for Pickering as the EME guides used for BDBAs contain a list of channelized indications powered by EME generators for Units 5-8. This list is in Appendix I of [B.11-19]. For Pickering Units 1,4 there is a list of EME indications in Table 2 of [B.11-20].

9. Clause 11.1.1 requires that the containment system include provisions for radiation shielding for all plant states defined in N290.0. For Pickering, this has been addressed in a BDBA habitability assessment [B.11-21].

10. Clause 12.1.2 requires the containment system design provide for isolation of all sources of compressed air and other non-condensable gases that are not needed for operation of the plant following an accident. This is a gap at Darlington since there is a design guide exception for the Powerhouse Service Air system.

    There was a similar gap for Pickering Units 1,4 against R-7 clause 3.10.3 [B.11-9]. Installation of the rupture panel system on Units 1,4 has resulted in a reduction of non-accident unit compressed air in-leakage. With this modification the Safety Report demonstrates that the post-accident containment pressurization times exceed 48 hours, which meets requirements set out by the CNSC.

    For Pickering Units 5-8, the RB bulkheads would be isolated post-accident to minimize compressed air in-leakage into containment after an accident. As a result the Safety Report demonstrates that the post-accident containment pressurization times exceed 48 hours for DBAs in Units 5-8. Therefore this gap is not applicable to PSR2.

11. Clause A.2 contains containment piping barrier requirements for systems connected to the containment atmosphere and provides acceptable configurations. A gap exists since there is an open design guide exception for the D_2O Leakage Collection System.

    This gap is specific to the design of a Darlington system and is not applicable to Pickering 1,4 or 5-8, and is therefore, not a PSR2 gap.

12. Clause A.5 (a) contains containment piping barrier requirements for crimping. The gap exists as there is an open design guide exception for two systems that do not have procedures in place to perform crimping of the required lines.

    This gap is specific to the design of Darlington systems and is not applicable to Pickering 1,4 or 5-8 and is therefore, not a PSR2 gap.

New Plant Requirements

In addition to the above, there were eight Darlington gaps identified against eight clauses relating to requirements for new plants. These are:

13. Clause 9.1.2 requires that the selection of the containment concrete material for new builds shall take into account the effects of severe accidents involving interaction of a melted reactor core and concrete. This was not addressed in the Darlington design and has not been addressed in the Pickering design. For Darlington, this was Gap 2286 and combined under Issue D607 [B.11-17] relating to BDBA and SAMG mitigation. The implementation of modifications in conjunction with improvements to SAMG were deemed to adequately compensate for the concrete used in the Darlington design. The same concept applies to Pickering, with a similar justification. Hydrogen is mitigated by the installation of PARs and improvements to SAMG for hydrogen management and mitigation. BDBA and SAMG strategies to stop accident progression in the In-Vessel Retention (IVR) state significantly reduce the risk of Core-Concrete Interaction (CCI). This clause has been acceptably addressed for Pickering and is not a PSR2 gap.

14. Clause 9.2.2.3 requires piping penetrations in new builds to be designed to be tested for leak tightness. In addition, Clause 9.2.3.2 requires each electrical and fibre optic cable penetration to be designed to be tested for leak tightness. Darlington had gaps relating to both clauses. Pickering did not have any gaps relating to R-7 Clause 5.2.4 which has the same requirement as Clause 9.2.2.3 of CSA N290.3. For Clause 9.2.3.2, Pickering does not use testable penetrations and instead relies on operational leak rate testing and Periodic Inspection Program (PIP) testing to confirm the leak tightness of containment. No fibre optic penetrations are used at Pickering. Darlington Gap 2306 was assigned to Clause 9.2.3.2 and was included in Issue D613 [B.11-15]. This gap was resolved as an acceptable deviation with low safety significance. The resolution notes that although the Darlington penetrations are equipped with testing capability, the benefit of the feature proved to be minimal. Similar to Pickering, Darlington relies on containment envelope leak rate testing. Given the above, although Pickering does not have individually testable electrical penetrations, this is acceptable based on the suitable alternate surveillance/testing being performed to assure the safety function is maintained. Therefore, this issue is not a PSR2 gap.

15. Clause 9.4.2.4 (b) requires that for BDBAs, if emergency venting is necessary to protect the structural integrity of containment, new plants shall be designed to minimize and to monitor the release of radionuclides. This was Gap 2290 noting that Darlington was not designed for BDBA venting and monitoring capability. A PSR2 Gap relating to enhancement of the power supply for the BDBA containment EMS and RMS has already been identified above. As a result of providing Phase 2 EME power to the FADS, the existing provisions for monitoring capability will be available. Hence, the ability to monitor releases is also addressed under the **PSR2 CSA N290.3-11 Gap #1** above.

16. Clauses 9.5.5 and 10.2.3 relate to provisions for sampling the containment atmosphere and monitoring the concentration of hydrogen. For containments that use inert atmosphere for combustible gas control, provisions for monitoring oxygen concentration shall be provided. These clauses were gaps for Darlington which identified that SAMG

would address measurement of hydrogen in Gaps 2291 and 2294. These have been combined in Issue D607 [B.11-17] relating to BDBA and SAMG mitigation, which notes that modifications are being made to reduce the potential for hydrogen production. Given that SAMG has been enhanced to provide improvements to the determination of hydrogen concentration and its mitigation, the requirement for hydrogen measurement instrumentation was classified as an Acceptable Deviation for Darlington. Pickering has installed PARs and implemented SAMG improvements to enhance hydrogen monitoring. Therefore, the absence of hydrogen monitoring instrumentation is acceptable, given there are alternate means of estimating hydrogen concentration through SAMG.

17. Clause B.3.1 requires pipes that connect to the reactor coolant system and penetrate the containment structure be provided with two isolation barriers. This is a similar requirement to Clause A.3.1 but also applies to pipes less than 25 mm for new plants. This was Gap 2307 and included in Issue D613 [B.11-15] for Darlington. This gap was classified as an Acceptable Deviation and the issue had low safety significance. There are some circumstances where it is possible to crimp small lines as a secondary containment barrier for Pickering Units 1,4 [B.11-22]. However, the rationale and classification of this issue as an Acceptable Deviation is also fully applicable to Pickering. Therefore, this is not a PSR2 gap.

18. Clause B.3.3 requires that for a pipe connected to the reactor coolant system with barriers open for 1 hour per year or more, both barriers shall be automatic and fail closed. The requirement is a change from the existing plant requirements in A.3.2 and A.3.3 where only the barrier inside containment was required to fail closed or to have a power operator. A similar requirement to A.3.2 and A.3.3 exists in the Design Guides for Darlington. However, Pickering 5-8 and Pickering 1,4 do not have reactor coolant systems (i.e., Heat Transport System, Shutdown Cooling, Moderator) that penetrate containment, therefore, this Darlington gap is not a PSR2 Gap for Pickering.

The above review for containment requirements for new plants has not identified any incremental safety significant gaps that are applicable to PSR2.

B.11.2.2 Application of Post PSR1 Reviews

The CSA N290.3-11 Impact Statement [B.11-23] provides a summary of significant features of the new standard. Containment boundary requirements are based on the requirements of CNSC R-7, therefore the compliance discussion for R-7 is still applicable. Of the features described, the only one considered to be safety significant for the purposes of PSR2 is that the standard includes requirements for the containment system for BDBAs and severe accidents.

A review of Darlington against N290.3-11 was discussed in Section B.11.2.1. For the clauses that contain requirements for BDBAs and severe accidents and are gaps for Darlington, the gap was assessed for applicability to Pickering. In addition, a review was completed to review the new clauses for BDBAs and severe accidents where Darlington was in compliance, to ensure the same is the case for Pickering. The following clauses fall into this category and the disposition for Pickering is provided:

- Clause 4.1(b) states [B.11-1]:

  The containment system shall consider BDBAs, including severe accident conditions.

  This is a general requirement which is addressed in more detail in subsequent clauses which have been addressed above for Pickering.

- Clause 5.5 states [B.11-1]:

  For each plant (existing and new build), the scope of DBAs and BDBAs shall be as agreed upon by the authority having jurisdiction (AHJ) and the licensee.

  This has been addressed by completing Fukushima Action Items and completing analyses for BDBAs and severe accidents.

- Clause 10.2.1 states [B.11-1]:

  The monitoring of containment conditions under BDBAs shall consider the guidelines in Annex A of CSA N290.6.

  Annex A is not a mandatory part of CSA N290.6 and therefore, outside the scope of PSR2.

Therefore, none of these clauses result in gaps for PSR2.

In addition, the N290.3 Impact Statement identifies that it captures existing Canadian industry and international standards and practices, including CNSC document R-7, which it replaces. Therefore, it is expected that Pickering will largely comply with N290.3-11. However, since this is the first version of the standard, this was confirmed by reviewing N290.3-11 to identify any significant issues that could impact Pickering's general compliance.

At a high level, the following demonstrates that the Pickering Units 1,4 and 5-8 Containment systems meet applicable nuclear safety objectives and licensing requirements:

- Performance requirements to ensure credits in the Safety Report are satisfied are contained in the OSRs for Pickering Units 1,4 and 5-8 [B.11-24] and [B.11-25].

- The Probabilistic Safety Assessment has demonstrated that public safety goals have been met with the design of the Pickering Containment system.

- Per Regulatory Document RD/GD-98 [B.11-26], unavailability analyses are completed that demonstrate that reliability requirements are met for the Containment systems.

- Environmental and seismic qualification requirements are in place to ensure the required performance following applicable design basis accidents.

For additional assurance, the requirements of N290.3-11 were reviewed to determine if there were any new requirements, or specific differences in the Darlington design compared to Pickering that could challenge Pickering's compliance with the new standard. Based on the review performed, there were no safety significant clauses that could impact on PSR2 other than those identified in B.11.2.1 above.

B.11.3 Compliance Summary for Pickering PSR2

There is one PSR2 CSA N290.3-11 gap which relates to Safety Factor 1 (Plant Design):

1. Per CSA N290.3-11, a Containment Energy Management System (EMS) and Radionuclide Management System (RMS) are required to protect containment and minimize radiological releases for Beyond Design Basis Accidents (BDBAs). The Pickering EMS and RMS use the Filtered Air Discharge System (FADS) and Reactor Building Air Cooling Units (ACUs). Enhancements to the AC power supplies to these systems and related loads are being provided by Phase 2 Emergency Mitigating Equipment (EME), which is not yet fully implemented. This PSR2 gap has been identified to track the implementation of Phase 2 EME such that it can be used to support the EMS and RMS.

B.12 CSA N290.4-11, "Requirements for Reactor Control Systems of Nuclear Power Plants"

B.12.1 Background

The following, paraphrased from the preface and scope of CSA N290.4 [B.12-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of CSA N290.4 is to specify provisions for safe and effective control of reactor power and pertains to all components of the system, including mechanical, process, software, electrical, and instrumentation and control design used for the control of the neutron flux and the thermal output of the reactor.*
>
> *CSA N290.4 establishes the minimum requirements for the design, manufacture and fabrication, qualification, and installation of reactor control systems in nuclear power plants, in order to ensure that they will operate as intended.*

All of N290.4-11 is directly relevant to Safety Factor 1 (Plant Design).

CSA N290.4-11 is the second edition of CSA N290.4. It supersedes the previous edition: N290.4-M82 published in January 1982 under the title "Requirements for the Reactor Regulating Systems of CANDU Nuclear Power Plants" [B.12-2].

Compliance with N290.4 is not currently a licence requirement for Pickering NGS (in accordance with PROL 48.02/2018) per the R04 Pickering Licence Condition Handbook [B.12-3].

The CSA Impact Statement notification for CSA N290.4-11 [B.12-4] provides a "Summary of Significant Changes from the Previous Edition" which identifies six changes to the Standard which are discussed in Section B.12.2 below.

The results of PSR1 N290.4 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.12.2. As identified in Reference [B.12-5], the Pickering PSR2 review of CSA N290.4-11 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.
- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.12.2 Compliance Assessment for Pickering PSR2

B.12.2.1 Application of PSR1 Reviews

The versions of CSA N290.4 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

A clause-by clause review of the Pickering Units 5-8 Reactor Regulating System (RRS) against the CSA N290.4-M82 [B.12-2] version of the Standard was documented in NK30-REP-03680-00001 R000 [B.12-6].

This review concluded that with the exception of two Acceptable Deviations (ADs), the Reactor Regulating System was in direct compliance with the design requirements stated in CSA-N290.4-82. The two ADs were as follows:

1. Clause 4.3.11 pertains to Reactor Power Start-up. This clause requires that if other special equipment is used for reactor start-up after long periods of shutdown, then that equipment may also have requirements imposed on it by N290.1. Start-up Instrumentation (SUI) is used in these circumstances at both Pickering Units 1,4 and 5-8 for this purpose. SUI may not fully conform with N290.1 such as the required areas of separation. However, the code review states that SUI is used under strict procedural controls and is used very infrequently and for limited periods of time. Therefore, the areas in which SUI may not comply with the requirements of N290.1 are not safety significant. This applies to both Pickering Units 1,4 and 5-8 SUI. In addition, related clauses 5.7 and 5.10.1 in N290.4-11 do not contain the requirement for SUI to meet N290.1 requirements. Therefore, this is not safety significant and not relevant for PSR2.

2. Clause 6.2.1 requires that a specific set of functional and performance requirements (contained in sub-clauses (a) though (j)) be documented in the RRS design manuals. Reference [B.12-6] states that not all of these aspects have been fully documented, but none of the omissions relate directly to the system design. Also, there is no corresponding requirement in the updated N290.4-11 version. This is not safety significant and not a PSR2 gap.

Pickering Units 1,4

As part of Pickering A Return to Service (PARTS), code reviews were conducted. The main submission for PARTS [B.12-7] committed to perform a review of N290.4-82 [B.12-2], which was the active version at that time. This review was completed in AECL Report, "Review of Pickering A Design Against Current Codes and Standards" [B.12-8]. This report concluded that, overall the design of Pickering Units 1,4 Reactor Regulating System complies with the design principles and requirements of CSA Standard N290.4-M82. The review identified four Acceptable Deviations in the following areas:

1. Clause 4.1 requires the reactor regulating system be physically and functionally separated from the special safety systems. (This is related to clause 5.2 in N290.4-11). Special safety systems and the regulating system are mostly independent of the major control loops, but there are three exceptions identified in the code review:

   - Sharing of taps and impulse lines from flow orifices in reactor flow measurement loops between RRS and Shutdown System A (SDSA). The code review states that irrational inputs to RRS control programs are rejected and SDSA channel flows are continually monitored in the control room to ensure they remain in the normal operating range. Therefore the impact of this exception is acceptable and not a PSR2 gap.

   - There are a number of RRS hardware and program interlocks related to the SDS system, e.g., gradually filling all zones when the reactor is tripped. These interlocks do not affect SDS functionality and are standard practice in CANDU design. Also, these interlocks drive RRS reactivity devices in the safe direction. Therefore the impact of this exception is acceptable and not a PSR2 gap.

   - In the control of moderator level, RRS and Emergency Coolant Injection (ECI) share some components, i.e., the common helium bubbler supply in the calandria and dump tank level measurements. The loss of the bubblers does not result in a loss of regulation, therefore there will be no postulated demand on either the in-core logic or ECI injection from this event and, therefore, sharing the bubblers is acceptable and not a PSR2 gap.

2. An AD is identified with clause 4.3.1.2 which requires that all components of the system (including power sources) shall be included in the reliability calculations. This clause is superseded by N290.4-11 clauses 5.4.2 and 5.4.3, which require the design target reliability of RRS be established in the Probabilistic Safety Assessment. The Pickering Units 1,4 Probabilistic Safety Assessment demonstrates that the RRS reliability including any supporting systems is acceptable. Therefore, this is not a PSR2 gap.

3. Clause 4.3.6.1 requires RRS to control neutron flux to obtain an acceptable spatial distribution and be capable of counteracting flux distortions that may otherwise lead to violation of fuel bundle or channel power limits. (This is related to N290.4-11 clause 4.1.2 (c)). Pickering Units 1,4 are not equipped with automatic reactor power setback or an alarm based on high flux tilt. Flux tilts are managed by operator monitoring and by the initiation of a power reduction as specified in operating manuals. This deviation has been accepted by the CNSC [B.12-9]. Therefore, this is not a PSR2 gap.

4. Clause 4.3.25.4 requires that where a number of channels of one system are in proximity, colour coding is the preferred identification method. This was not implemented into the Pickering Units 1,4 RRS. This requirement is referred to in clause 5.11.4 in N290.4-11 as one of several methods of facilitating human-system interface in the design and, therefore, is still relevant. However, the design of the RRS control room panels are clearly organized and labeled, such that colour coding is not required. Therefore, this is not a PSR2 gap.

Darlington NGS

The original code review for the Darlington ISR, as documented in OPG Report NK38-REP-03680-10012 R000 [B.12-10], was performed against CSA N290.4-82 [B.12-2]. In general it was found that the Darlington design of the Regulating Systems meets the requirements of N290.4-M82. NK38-REP-03680-10012 does identify the following gap[12]:

(i) Start-up Instrumentation (SUI) - SUI is a part of both RRS and Shutdown Systems and SUI meets all requirements for RRS with respect to permanently installed equipment. However, for SUI in terms of SDS function, it may not meet all requirements of CSA N290.1 (e.g., separation environmental and seismic), which N290.4-M82 explicitly references (clause 4.3.11).

The code reviews for both Pickering Units 5-8 and Units 1,4 reviewed above addressed this issue. For Pickering Units 5-8 there was an acceptable deviation against this clause. For Pickering Units 1,4 it was stated that there was direct compliance. Given the similarity of the SUI used in Units 5-8 and 1,4, it is judged that there is an acceptable deviation for both stations against this clause. As per the compliance assessment for Pickering Units 5-8 on this clause, the new version of N290.4 does not contain the same clause, therefore there is no PSR2 gap associated with this issue.

Following the issuance of CSA N290.4-11 [B.12-1], a Code Refresh review was conducted and documented in OPG Report NK38-REP-03680-10156 R000 [B.12-11].

The clause-by-clause review in the report does not discuss the differences between CSA N290.4-11 [B.12-1] relative to CSA N290.4-M82 [B.12-2] because the new standard is a major, "technology neutral" revision that is applicable also for light water reactors.

The review confirmed that OPG Nuclear and DNGS governance are in compliance with the requirements in CSA N290.4-11, except for the following requirement. Clauses relating to Anticipated Operational Occurrences (AOOs) (e.g., Clause 4.2) require the capability of the Reactor Regulating System be assessed to deal with AOOs, by preventing them from escalating into Design Basis Accidents (DBAs) that would require Shutdown System action.

In general the Setback function (and Stepback in Pickering Units 5-8) addresses these requirements; however, AOOs have not been identified and analyzed in the current Pickering Safety Reports. This is therefore identified as **PSR2 CSA N290.4 Gap #1.** There are also additional clauses which refer to requirements of RRS during AOOs, specifically: Clause 5.19 RRS and core stability; Clause 5.6.2 reactivity depth and rate of change; and, Clause 5.16.1 environmental qualification. These clauses are also captured under Gap #1.

Clause 5.19 of CSA N290.4-11 is specific to new plant design and relates to RRS control stability. For Darlington, Gap 1702 was identified against this clause, specifically relating to RRS requirements for AOOs. This gap was included in Issue D332 [B.12-12] and the resolution in the Integrated Implementation Plan (IIP) [B.12-13] is to address this issue as part of IIP-OI-

---

12 Another gap was originally identified for clause 6.2.2 of CSA N290.4- M82; however, it was re-classified as compliant in Appendix B of [B.12-10].

043 (or AI 2014-OPG-5461) relating to CNSC REGDOC 2.4.1 compliance. This issue is also a gap for PSR2; however, it is included in **PSR2 CSA N290.4 Gap #1** above. Issues related to AOOs are being addressed as part of REGDOC-2.4.1 implementation and the current REGDOC-2.4.1 implementation plan is documented in N-PLAN-03500-0500515 R03 [B.12-14].

In terms of the more general issue of core stability, given the many years of operation for Pickering 5-8 and 1,4, there is operating experience to demonstrate that reactor control is stable and robust for normal operation. Reference [B.12-15] documents a core stability assessment for Pickering 1,4 concluding that spatial control is adequate. Therefore, the issue of core stability for normal operation is not a PSR2 gap.

B.12.2.2 Application of Post PSR1 Reviews

CSA N290.4 has been updated since the last code reviews were performed for Pickering. It was updated to N290.4-11 [B.12-1] in 2011 from the original version N290.4-M82 [B.12-2]. A review of changes to N290.4 and Pickering's compliance with them are discussed in this section.

Given the extent of the changes in N290.4-11 [B.12-1] and lack of specificity in the Impact Statement [B.12-4], a review of changed clauses was performed. There were a number of changes made in the update of the code, with some resulting in intent changes. However, in the majority of cases, though wording was revised compared to N290.4-M82, there were no additional significant intent changes. The code was re-organized, the requirements made less specific and modified to be technology neutral. Detailed requirements were removed in cases where reference to another standard can be made, e.g., N290.13 on Environmental Qualification.

Of the six changes listed in the CSA Impact Statement for the issue of N290.4-11 [B.12-4], only two have the potential to have an impact on nuclear safety.

These are:

a) It has been aligned with regulatory document RD-337 [B.12-16]; and

b) Additional requirements have been added in the following areas: Human-System Interface, Cyber Security, Chemistry, Software Design, Aging Management, Reactivity Management.

Alignment with RD-337

Regulatory Document RD-337, "Design of New Nuclear Power Plants" [B.12-16][13] introduces new requirements for the assessment of AOOs. N290.4-11 contains various clauses referring to RRS requirements in the event of AOOs. This has already been addressed in **PSR2 CSA N290.4 Gap #1**.

---

[13] Now superseded by CNSC REGDOC 2.5.2 "Design of Reactor Facilities: Nuclear Power Plants" [B.12-17].

Human-System Interface

Clause 5.11 introduces requirements for the human factors engineering design process, including the development of a human factors plan and usability requirements.

Currently Human Factors Engineering (HFE) is considered for all design changes. The changes are managed through the Engineering Change Control Program [B.12-18] and plant modifications follow the Modification Process [B.12-19]. The Design Scoping Checklist [B.12-20], which is a component of the modification process, identifies the level of HFE required. If the modification is judged to have an HFE impact, then the Human Factors Level of Activity [B.12-21] is completed to determine the scope of the HFE. A Human Factors Engineering Specialist must concur with the Human Factors Level of Activity. The modification may require the preparation of a Human Factors Engineering Program Plan or the Human Factor Worksheet [B.12-22]. These instructions and processes ensure that the human-system interface elements for the modification are addressed. The technical, design and operator reviews during and following the design process and via the Operations Turnover process ensure the usability requirements will be achieved.

The Human Factors Engineering Program Plan prepared by OPG meets the requirements of CNSC G-276 [B.12-23] and CNSC G-278 [B.12-24] and applicable elements from NUREG-0711 [B.12-25]. The results are independently verified. Therefore, the intent of these clauses is met.

Cyber Security

Clause 5.18 identifies the consideration for cyber security. OPG has a program in place to ensure cyber security requirements are in place as per OPG Procedure, N-PROC-MP-0103, "Security for Real-Time Process Computing Systems" [B.12-26]. This clause is met.

Chemistry

Clause 5.20 contains the following requirement:

> *The design of the reactor control system shall facilitate the monitoring and control of isotopic values and soluble neutron absorbers used for reactor power control such that reactivity worth is known.*

The concentrations of the relevant chemicals in the moderator to control reactivity are measured routinely and controlled [B.12-27], [B.12-28]. Therefore, there is no PSR2 gap associated with this new clause.

Software Design

Clause 5.17 identifies requirements for software design. OPG has a comprehensive program for managing software development, including real-time RRS software [B.12-29].

Aging Management

Four new clauses have been added in Section 5.16.4 dealing with equipment Aging Management. The current regulatory requirements for an Aging Management program are contained in CNSC REGDOC-2.6.3, "Aging Management" [B.12-30]. A code review was performed of this regulatory document in Report P-REP-03680-00004 [B.12-31]. The review concludes OPG is in compliance with REGDOC-2.6.3 except in two areas. Neither of these areas affect compliance with the N290.4 clause 5.16.4. Pickering is compliant with this clause.

<u>Reactivity Management</u>

The standard identifies the following relating to reactivity management:

> **Note:** *For the purposes of this Standard, "reactivity management" refers to*
> *(a) the safe, controlled, and conservative performance of plant operation and maintenance activities that affect reactivity;*
> *(b) the active and vigilant monitoring of reactivity changes;*
> *(c) the quick and reliable detection of deviations from expected results; and*
> *(d) limiting rate changes and maximum power changes in response to failures.*

Clause 5.1 relates to incorporation of operating experience from reactivity management events into control system design. Clause 5.13.1 relates to avoidance of reactivity control events due to maintenance activities. There is an OPG nuclear standard specific to reactivity management [B.12-32] that deals with Operations and Maintenance requirements for reactivity management. In addition reference [B.12-32] addresses reactivity management performance monitoring and reporting. The Pickering reactivity control system designs are mature; however, any changes relating to reactivity control mechanisms require operating experience to be considered and dissemination of industry reactivity management operating experience to stakeholders (e.g., control room operators). This is addressed in reference [B.12-32].

B.12.3 Compliance Summary for Pickering PSR2

There is one PSR2 CSA N290.4-11 gap which relates to Safety Factor 1 (Plant Design):

1. Clause 4.2 and Clause 5.19 of CSA N290.4-11 require the capability of the Reactor Regulating System (RRS) to be assessed to deal with Anticipated Operational Occurrences (AOOs), by preventing them from escalating into Design Basis Accidents (DBAs) that would require Shutdown System action. In general, the setback function (and stepback in Pickering Units 5-8) addresses this requirement; however, AOOs have not been identified and analyzed in the current Pickering Safety Reports. Therefore, this has been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation. Note: There are also additional clauses which refer to requirements of RRS during AOOs (Clauses 5.6.2, 5.19, 5.16.1); however, for convenience, all issues related to AOO requirements for RRS in N290.4-11 are captured under this one PSR2 gap.

B.13 CSA N290.5-06, "Requirements for Electrical Power and Instrument Air Systems of CANDU Nuclear Power Plants"

B.13.1 Background

The following, paraphrased from the Preface and Scope of CSA N290.5-06 (R2011) including Update No. 1 [B.13-1] provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *CSA N290.5 specifies design, procurement, qualification, construction, installation, inspection, and documentation requirements to ensure that CANDU electrical power and instrument air systems meet nuclear safety requirements.*

All of N290.5-06 (R2011) including Update No. 1 is directly relevant to Safety Factor 1 (Plant Design).

CSA N290.5 is identified in Appendix E.1 of the R04 Pickering Licence Conditions Handbook [B.13-2] as "Guidance or Criteria". Section 6.1, "Design Program" of [B.13-2] states that "Recommendations and guidance are found in… N290.5, which covers electrical power and instrument air systems."

CSA N290.5-06 (R2011) including Update No. 1 [B.13-1] was issued in November 2011 and is the second edition of CSA N290.5. This edition including Update No. 1 supersedes the following versions of the standard:

(i) N290.5-M90, published in 1990 under the title "Requirements for the Support Power Systems of CANDU Nuclear Power Plants" [B.13-3], and

(ii) N290.5-06 published in December 2006 under the title "Requirements for Electrical Power and Instrument Air Systems of CANDU Nuclear Power Plants" [B.13-4].

The CSA Impact Statement notification for Update No. 1 to CSA N290.5-06 [B.13-5] provides a "Summary of Significant Changes from the Previous Edition" which identifies five primary changes to the Standard which are discussed in Section B.13.2 below.

The results of PSR1 N290.5 reviews (Pickering A Return to Service (PARTS) assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.13.2. As identified in Reference [B.13-6], the Pickering PSR2 review of CSA N290.5-06 including Update No. 1 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard (L/R/C/S) on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.

- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.13.2 Compliance Assessment for Pickering PSR2

B.13.2.1 Application of PSR1 Reviews

The versions of N290.5 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

For Pickering B ISR Safety Factor 1, a clause-by clause review of Pickering Units 5-8 against the CSA N290.5-M90 version of the Standard was documented in NK30-REP-03680-00001 R000 [B.13-7]. CSA N290.5-M90 was titled, "Requirements for the Support Power Systems of CANDU Nuclear Power Plants", which is different from the latest version of the Standard: "Requirements for Electrical Power and Instrument Air Systems of CANDU Nuclear Power Plants". Although the two titles are different, the scope of the two documents is restricted to the same systems, i.e. Electrical and Instrument Air (IA).

NK30-REP-03680-00001 R000 [B.13-7] concluded that the designs of the Pickering Units 5-8 Class I, II, III, IV, Site Electrical System, and Emergency Power Supply electrical systems were found to comply with the design requirements of the Standard. There was one Acceptable Deviation on Reference Publications referred to in the Standard, however, this has no impact on nuclear safety. This report did not address the Instrument Air system in the scope of the review since Instrument Air is not a Safe Operating Envelope (SOE) system or System Important to Safety (SIS) and the local air reservoirs were considered adequate to perform the safety function, per Appendix B of Reference [B.13-7].

Because backup IA has credited safety functions and the PSR2 Basis Document [B.13-6] contains a requirement to address specific components in non-SOE systems when they play a role in the plant safety basis, an assessment of Pickering Units 5-8 against the IA portions of CSA N290.5-06 (R2011), including Update No. 1 [B.13-1], has been provided in Section B.13.2.2 below. As discussed in Section B.13.2.2, the review demonstrated that the Pickering Units U5-8 IA system complies with the updated version of this code.

Pickering Units 1,4

As part of PARTS, code reviews relevant to N290.5 were conducted. The main submission for PARTS [B.13-8] committed to perform a review of N290.5-M90 [B.13-3]. This review was completed in AECL Report, "Review of Pickering A Design Against Current Codes and Standards" [B.13-9]. This report concluded for Electrical Systems that, overall the design of Pickering 'A' Electrical Distribution systems complies with the design principles and requirements of CAN/CSA N 290.5-M90, for Class I, II, III and IV power systems.

One Acceptable Deviation was identified against clause 5.4.4.2 regarding the use of a single rectifier for each Class I battery. This was considered acceptable since rectifier failures are annunciated and the associated battery has adequate capacity to allow time for operator action. This clause has not changed in the latest code version and states:

> *The number of rectifiers for each battery shall be determined by the reliability requirements for dc power.*

Per Regulatory Document RD-98, reliability targets are set for Systems Important to Safety (SIS). The Class I power system is in the list of SIS and therefore it is a monitored system required to meet its reliability target. Since the reliability of the system has been demonstrated to be acceptable with its current design, the Acceptable Derivation remains applicable and there is no PSR2 gap against this clause.

Two instances were identified where non-compliances with the code existed. These dealt with (i) DC contactor ratings for the Motor Generator (MG) Sets and (ii) On-line testing of distribution systems. In both cases, replacement of the MG sets prior to return to service addressed these non-compliances.

A compliance review of the Instrument Air System against N290.5-M90 was not completed as part of this PARTS code review. As discussed under Section B.13.2.2 below, significant work was performed on the IA system during the Pickering A Return to Service and therefore a compliance review was judged as not required at that time. Subsequent to this, the CNSC requested that Pickering Units 1,4 submit a compliance review of N290.5 for instrument air. This was completed in 2011 and documented in Reference [B.13-10]. Since the PARTS review, a new version of the code CSA N290.5-06 including Update No. 1 [B.13-1] was issued and was used for the compliance review. This review demonstrated that the Pickering Units 1,4 IA system complies with the updated version of this code. All requirements of the Standard were reviewed clause-by clause.

Darlington NGS

The original code review of the Darlington ISR, as documented in OPG Report NK38-REP-03680-10013 R000 [B.13-11], was performed against CSA N290.5-06 (2006). In general it was found that the Darlington designs of Electrical Power and Instrument Air systems meet or exceed the requirements of N290.5-06. NK38-REP-03680-10013 does identify gaps against clauses for both systems. The majority of the gaps were related to updating of Electrical Transient Analysis Program (ETAP) calculations to demonstrate system capabilities for all the Classes of power systems as well as for the two Groups of power[14]. This was not identified as a gap in the Pickering Units 5-8 code review of N290.5-06 [B.13-1] or in the Pickering Units 1,4 code review of N290.5-M90 [B.13-3]. Also, there is a requirement in the Engineering Change Control governance to maintain ETAP models current. Therefore this is not considered a PSR2 gap.

---

[14] Two other gaps were identified; however they were re-classified as compliant in Appendix B of [B.13-11].

Following the issuance of CSA N290.5-06 (R2011) including Update No. 1 [B.13-1] in November 2011, a Code Refresh review was conducted and documented in OPG Report NK38-REP-03680-10157 R000 [B.13-12].

The significant changes made in CSA-N290.5-06 (R2011) including Update No. 1 relative to CSA-N290.5-06 were the inclusion of new requirements with respect to Beyond Design Basis Accidents (BDBAs), degradation of the off-site electrical grid, and aging management. This aligns with the information provided in the CSA Impact Statement notification for Update No. 1 to CSA N290.5-06 [B.13-5].

NK38-REP-03680-10157 R000 [B.13-12] identifies that Darlington is in compliance with the requirements of CSA-N290.5-06 (R2011) including Update No. 1 [B.13-1] with the exception of three clauses that have ISR Gaps related to BDBAs. These gaps are programmatic in nature and it was stated that OPG governance is being updated to include the Management of BDBAs for all stations. These gaps apply to Pickering and will be discussed in the next section.

B.13.2.2 Application of Post PSR1 Reviews

CSA N290.5 has been updated twice since the last code reviews were performed for Pickering. It was first updated to N290.5-06 in 2006. In 2011 Update No. 1 to N290.5-06 was issued [B.13-1]. A review of changes to N290.5 and Pickering's compliance with them are discussed in this section separately for the Electrical and Instrument Air systems.

Electrical Systems

As described above, a code review for Electrical systems was last completed for Pickering Units 1,4 against N290.5-M90 in Reference [B.13-9]. For Pickering Units 5-8, the latest code version reviewed was also N290.5-M90 in Reference [B.13-7]. Two changes to the code have been made since these reviews, i.e. N290.5-06 and N290.5-06 (2011) including Update No. 1. The significant intent changes to the code that could have an impact on nuclear safety are described below, including Pickering's compliance to them at a high level.

<u>Changes from Code Versions N290.5-M90 to N290.5-06</u>

These changes were not contained in a CSA Impact Statement, so they were determined based on a review of the two code versions to identify significant changes.

- Clause 4.2 – Use of Software (this is a common requirement applicable to IA as well)

  This new clause identifies requirements for software categorization, design, coding, etc.

  The OPG Program N-PROG-MP-0006 R009, "Software" [B.13-13], which includes Procedure, N-PROC-MP-0049 R009, "Procurement of Software and Products Containing Software" [B.13-14], is in place and demonstrates compliance with this clause.

- Clause 5.5.3.3 – Conversion Equipment Characteristics

  This new clause provides requirements for conversion equipment providing AC power (e.g., inverters, MG Sets) with respect to limits on frequency deviation and drift that are consistent with the requirements of the control equipment it supports. Additionally, output AC frequency is not to be dependent on nominal grid frequency. Pickering NGS demonstrates compliance with this clause in that limits on frequency characteristics are prescribed for conversion equipment by Class II Power Design Requirements that meet the requirements of supplied loads with sufficient margin. These Design Requirements are outlined in Appendix B of [B.13-15] and Section 3.4 of [B.13-16] for Pickering Units 1,4 and Units 5-8, respectively.

- Clause 5.5.3.4 – Conversion Equipment Level of Quality

  This new clause provides requirements for the level of quality of the power delivered by inverters or MG Sets to Class II loads, e.g., frequency variation, voltage variation, and voltage distortion. Pickering NGS demonstrates compliance with this clause in that limits on power quality characteristics are prescribed for conversion equipment by Class II Power Design Requirements that meet the requirements of supplied loads with sufficient margin. These Design Requirements are outlined in Appendix B of [B.13-15] and Section 3.4 of [B.13-16] for Pickering Units 1,4 and Units 5-8, respectively.

Changes from Code Versions N290.5-06 to N290.5-06 (R2011) including Update No. 1

These changes are extracted from the CSA Impact Statement [B.13-5] for the amended issue of N290.5-06 to N290.5-06 (R2011) including Update No. 1.

- Clauses 4.1 (m), 5.1.3.2 and 5.1.3.3 - Beyond Design Basis Accidents (BDBAs) (applicable to instrument air as well)

  These are new clauses dealing with requirements for BDBAs. Clause 4.1 (m) states that design features or strategies to manage BDBAs shall be considered in the design of electrical power and instrument air systems. Clause 5.1 provides general design requirements for electrical power systems: Clause 5.1.3.2 requires identification of BDBAs resulting from common cause events; Clause 5.1.3.3 requires consideration of design features or strategies for the identified common cause BDBAs. Clause 6 provides design requirements for instrument air systems; there are no requirements related to BDBAs. Both Pickering Units 1,4 and Units 5-8 have addressed BDBAs in their design, including preparation of operating procedures and provisions for connecting temporary generating equipment. No additional equipment is required to supply instrument air, as back-up air provisions to safety related equipment can fulfil their function after a postulated BDBA. Guides have been issued for both Pickering Units 1,4 and Units 5-8 describing the Functional Safety Requirements for BDBAs [B.13-17], [B.13-18], which include requirements for electrical equipment. This demonstrates compliance with these clauses.

- Clauses 5.1.7.1 and 5.1.7.2 - Degradation of the Off-Site Electrical Grid

  These are new clauses dealing with the requirements for:

  (i) The response of nuclear safety related functions during sustained grid frequency and voltage excursions

(ii) The plant continuing to produce electrical power during sustained grid frequency and voltage excursions

The purpose of these two new requirements is to ensure grid survivability so that safety related systems, e.g. Standby Generators and Emergency Power Generators, are not unnecessarily challenged. With regard to continued power generation during grid excursions, Pickering NGS must be compliant with the Ontario Independent Electricity System Operator (IESO) Market Rules, including MDP_RUL_0002_04A, "Chapter 4 – Grid Connection Requirements – Appendices" [B.13-19]. These rules ensure compliance with Clauses 5.1.7.1 and 5.1.7.2; therefore, no PSR2 gap exists with respect to these Clauses.

- Clause 7.1 on Equipment Qualification under normal operation and Anticipated Operational Occurrences (AOOs) (applicable to instrument air as well).

  This clause introduces the general requirement for components to be qualified to perform their required functions during normal operation and AOOs. Only the portion of this clause on AOOs is pertinent to nuclear safety. AOOs have not been identified and analyzed in the current Pickering Safety Reports. Hence, the requirements and credits attributed to the Electrical Power and Instrument Air systems for AOOs cannot be readily ascertained. This is therefore identified as **PSR2 CSA N290.5-06 Gap #1.**

- Clause 7.4 - Aging Management (applicable to instrument air as well).

  Four new clauses have been added dealing with equipment Aging Management. The current regulatory requirements for an Aging Management program are contained in CNSC REGDOC-2.6.3, "Aging Management" [B.13-20]. A code review was performed of this regulatory document in Report P-REP-03680-00004 R000 [B.13-21]. The review concludes OPG is in compliance with REGDOC-2.6.3 except in two areas. None of these areas affect compliance with the N290.5 clause 7.4.

  However, since clause 7.4.2 raises the AOO plant state in its requirement, as per clause 7.1, there is a gap against clause 7.4.2. This is already addressed by **PSR CSA N290.5-06 Gap #1** above.

Instrument Air

As described above, a code review for the Instrument Air systems was last completed for Pickering Units 1,4 against N290.5-06 in Reference [B.13-10]. For Pickering Units 5-8, there has not been a review performed against any versions. Given this, Pickering Units 1,4 and Pickering Units 5-8 will be discussed separately.

Pickering Units 1,4

As stated above, Reference [B.13-10] demonstrated that the Pickering Units 1,4 Instrument Air System is in compliance with N290.5-06. The changes made in code version N290.5-06 (R2011) including Update No. 1 were described earlier. There were no changes made to the IA system sections of the code. Only the changes to the common sections of the code, i.e. in clauses 4.1(m), 7.1 and 7.4, apply to IA as well. The compliance discussion for these clauses was already addressed above, so there are no additional PSR2 gaps for the IA sections of the current code version.

Pickering Units 5-8

As described above, a compliance review against the IA system portions of CSA N290.5-06 (R2011) including Update No. 1 [B.13-1] was not undertaken as part of previous Pickering Units 5-8 PSR1 reviews and the following assessment has therefore been completed. In the review below, the degree of conformance with clauses or groups of clauses in the L/R/C/S is assessed for Pickering NGS by reference to supporting evidence stating whether the intent of the requirements stipulated in the L/R/C/S is met. (Note that in instances where multiple sub-clauses are addressed they have been summarized and rolled-up into a more general paraphrased summary statement. In cases where only one clause is assessed it has been transcribed here and included in italics.). The review demonstrated that the Pickering Units 5-8 IA system complies with the updated version of this code, and therefore there are no PSR2 gaps.

CSA N290.5-06 Clause	PSR2 Review	Compliant or Gap
6 Design requirements — Instrument air system	See subsections below.	N/A
6.1 General 6.1.1 System design – the instrument air system shall be arranged to ensure a reliable supply of dry, oil-free compressed air supplied from Class III electrical and include permanently connected air storage tanks or compressed gas bottles to ensure an uninterrupted supply as per plant documentation and in accordance with CSA N285. 6.1.2 Failure of non-safety-related loads – shall not impair the instrument air system as a result of Design Basis Accidents (DBAs).	See subsections below. As detailed in Design Manual NK30-DM-75120-00001 R000 [B.13-22], the unitized Pickering U5-8 instrument air supply equipment includes oil free air compressors, dryers, filters and air receivers, and is capable of supplying air at a nominal gauge pressure of 860 kPa (125 psi) suitably conditioned by drying to a dew point below -40°C (-40°F) and filtered to a particle size less than 1 micron. The instrument air compressors are supplied from either Class IV or Class III power. In the event of a loss of Class IV power, Class III power will be able to supply the compressors prior to depleting the instrument air and air receivers [B.13-22]. Per the Design Requirements, NK30-DR-75120-10003 R001 [B.13-23], local emergency bottles provide an alternate, non-interruptible, air supply for nuclear safety related loads. The Instrument Air system is designed and registered in accordance with CSA Standard B51 [B.13-23]. All instrument air stations installed in U5-8 are provided with either single or double manifolds, each having eight outlets complete with isolation valves and a shut-off root valve and drain valve [B.13-22]. The instrument air distribution piping through the plant, including the Turbine Hall, Turbine Auxiliary Bay (TAB), Reactor Auxiliary Bay (RAB) and Reactor Building, includes components such as air receivers, air stations and other major equipment which have isolation and/or non-return valves in order to be able to isolate specific equipment, portions of the system, or specific branches of the piping, should it be required as a result of a DBA.	Compliant

CSA N290.5-06 Clause	PSR2 Review	Compliant or Gap
6.1.3 Instrument air for other purposes – design shall ensure that the instrument air system is not impaired by the operation or failure of non-safety-related loads.	The distribution system consists of a ring header, providing two alternate routes to any point in the Turbine Building, TAB, RAB and the Reactor Building. Manual isolating valves on the ring header have been provided for emergency isolation so that the instrument air supply to the remaining headers will not be jeopardized [B.13-22]. Hence the design of the Instrument Air system provides isolation such that the Instrument Air system supplying safety related loads is not impaired by the failure of non-safety related systems or loads. Furthermore, dedicated backup instrument air supplies, i.e., local air bottles, supply air to safety related loads in the event of the loss of the normal supply. Based on the above, the Pickering U5-8 Instrument Air system meets the intent of Section 6.1 of CSA N290.5-06.	
6.2 Safety-related considerations 6.2.1 Supply to safety-related loads – in accordance with the nuclear safety requirements and plant design documentation. 6.2.2 Isolation of loads – via an instrument air manifold take-off valve to facilitate maintenance and protect upstream supplies.	See subsections below. The Backup Instrument Air Design Requirements, NK30-DR-75120-10003 R001 [B.13-23], state that during normal operating conditions instrument air to each unit's loads are drawn from the normal instrument air supplied by its unitized compressors. Additional redundancy is provided by backup instrument air supplies, consisting of local, seismically qualified, instrument air bottles and associated distribution components that connect to the Instrument Air system. As per Section 11.2.1 of the Safety Report [B.13-24] backup instrument air equipment provides readily available capacity for the nuclear safety related equipment (including Emergency Coolant Injection System, Airlocks and Pressure Relief Panel Bypass Valves) requiring a non-interruptible air supply in the event of a loss of the normal instrument air supplies. Per [B.13-23] backup instrument air equipment is credited following design basis events such as: a) Loss of Normal Instrument Air b) Main Steam Line Breaks c) Design Basis Earthquakes d) Loss of Coolant Accident (LOCA) followed by Site Design Earthquake 24 hours later As described in 6.1.2 all instrument air stations installed in U5-8 are provided with either single or double manifolds, each having eight outlets complete with isolation valves, and a shut-off root valve and drain valve [B.13-22]. Isolation of specific air stations, and individual loads supplied by those stations, is accomplished through these isolation valves. These isolation points both facilitate maintenance and protect upstream supplies.	Compliant

CSA N290.5-06 Clause	PSR2 Review	Compliant or Gap
6.2.3 Supply to redundant loads – as required for the operation of a nuclear-safety-related load via either sufficient air supply separation or an alternate air supply such as local air storage tanks.	As per 6.1.1 a redundant air supply is provided by backup instrument air equipment consisting of local, seismically qualified, instrument air bottles and associated distribution components that connect to the Instrument Air system. Non-return valves are incorporated into the design to provide separation from the normal air supply, if it were to become unavailable. As per Section 11.2.1 of the Safety Report [B.13-24] backup instrument air equipment provides readily available capacity for nuclear safety related equipment.	
6.2.4 Reliability – requirements for air compressors with associated air receivers, filters, dryer equipment and cooling water system.	The Instrument Air system is not a System Important to Safety requiring an unavailability target per RD/GD-98 and does not have reliability requirements specified. However, backup instrument air equipment is credited for safety and has specified reliability targets [B.13-23]. Nevertheless, the system is designed with redundancy that supports reliable operation. The configuration of air supply compressors and associated air receivers, filters, dryer equipment and cooling water systems include redundancy considerations which support system reliability. Instrument air to each unit is supplied by four 33%, 0.307 m^3/s (650 SCFM), 860 kPa gauge (125 psig), two stage, water cooled oil free rotary screw compressors each driven by a 150 kW (200 hp) motor. One set of dual prefilters and afterfilters is provided for the four air dryers to remove both solid and liquid particles. Each filter, of a set of two, is capable of a 0.66 m^3/s (1400 SCFM) capacity [B.13-22]. The four air compressors discharge into four 7.0 m^3 (250 cu ft) air receivers that are arranged in parallel and are connected downstream of the four air dryer units by a common header [B.13-22].	
6.2.5 Common headers - may be used between the redundant air compressor/filter equipment and the air storage tanks.	Interconnections are not used between redundant air compressor equipment and air receivers belonging to another compressor set; however, the air receivers are joined by the common header and can be charged from each operating compressor as shown on the compressor flow diagram for U5 [B.13-25]. Based on the above, the Pickering U5-8 Instrument Air system meets the intent of Section 6.2 of CSA N290.5-06.	

CSA N290.5-06 Clause	PSR2 Review	Compliant or Gap
6.3 Protection against localized and common-cause events 6.3.1 Loss of instrument air – safety related equipment and the required air supplies shall either be isolated from the effects of DBAs or hardened to be immune to them. 6.3.2 Group 1 and Group 2 capability – shall meet nuclear safety requirements for local and common cause events.	See subsections below. As outlined in the Instrument Air Design Manual, NK30-DM-75120-00001 R000 [B.13-22], the air receivers and downstream air stations are distributed spatially in the plant. The air receivers are equipped with non-return valves to prevent them from being depleted, as described in Clause 6.5. The Instrument Air system is not protected for common mode DBAs. Backup instrument air equipment provides a seismically and harsh environment qualified alternate air supply which is credited for a variety of DBAs as described in Clause 6.2.1. This is accomplished by means of compressed air bottles which supply selected safety related loads for given mission times to ensure critical control, cooling and containment functions are maintained, or to provide sufficient time to allow for subsequent field actions. In accordance with the nuclear safety requirements and plant design documentation, backup instrument air equipment provides a seismically qualified alternate air supply to Group 2 pneumatic loads required to operate following a DBA. See the Pickering Safety Report [B.13-24] and Backup Instrument Air Design Requirements, NK30-DR-75120-10003 R001 [B.13-23], for details. Based on the above, the Pickering U5-8 Instrument Air system meets the intent of Section 6.3 of CSA N290.5-06.	Compliant
6.4 Reliability *The reliability of the instrument air supply shall be commensurate with the requirements of the connected safety-related systems.* *Note: Reliability requirements can be achieved by providing air to redundant devices from different instrument air take-off valves and providing an alternate air supply for those devices that need air following events that disable the normal air supply system.*	The reliability requirements for backup instrument air to loads is satisfied by bottled air supplies. The reliability of these supplies is commensurate with the requirements of the load(s) [B.13-23]. Reliability requirements are further enhanced by design provisions, such as the presence of local air receivers in various parts of the system, diverse supplies to redundant loads and alternate flow paths to many parts of the system. See Clause 6.2.4 which outlines additional redundancy provisions that contribute to system reliability. Based on the above, the Pickering U5-8 Instrument Air system meets the intent of Section 6.4 of CSA N290.5-06.	Compliant

CSA N290.5-06 Clause	PSR2 Review	Compliant or Gap
6.5 Isolating devices *Non-return valves shall be provided upstream of each air storage tank to maintain the short-term air supply to safety-related loads after loss of the upstream air supply. Isolation valves shall be provided on the distribution system to facilitate maintenance and testing and to mitigate the impact of header failures.*	The four main compressors' air receivers are fitted with non-return valves upstream of their inlets. As an example refer to the U5 flow diagram, NK30-FEH-75120-0001-U5 R006 [B.13-25]. Furthermore, as per the Instrument Air Design Manual, NK30-DM-75120-00001 R000 [B.13-22], each of the eleven local air receivers in the unitized instrument air distribution systems are equipped with a check valve to prevent back flow into their supply line. The check valves prevent air in the receiver from escaping should a line break occur in the upstream piping. These design provisions ensure there is sufficient air supply to loads in the short term. The distribution system consists of a ring header, providing two alternate routes to any point in the Turbine Building, Turbine Auxiliary Bay, RAB and the Reactor Building. Manual isolating valves on the ring header are provided for emergency isolation so that the instrument air supply to the remaining headers will not be jeopardized. All instrument air stations installed in the units are provided with either single or double manifolds, each having eight outlets complete with isolation valves and a shut-off root valve [B.13-22]. These valves both facilitate maintenance and testing and mitigate the impact of header failures. Based on the above, the Pickering U5-8 Instrument Air system meets the intent of Section 6.5 of CSA N290.5-06.	Compliant
6.6 Monitoring and testing *The instrument air system shall have appropriate monitoring and testing facilities so that the operator can confirm that the system is capable of performing its intended functions. Where a common alternate air system uses high-pressure gas cylinders, system surveillance or an alarm for operator response shall be provided. The action limits for the surveillance or the alarm shall be such that the alternate instrument air system remains available.*	Monitoring and testing of instrument air facilities is facilitated by air sampling throughout the plant in accordance with ANSI standard ISA-S7.3 as per OPG Chemistry Laboratory Procedure, P-CLP-75100-0001 R004 [B.13-26]. As detailed in the Instrument Air Design Manual, NK30-DM-75120-00001 R000 [B.13-22], monitoring of the Instrument Air system is accomplished through a variety of indications and alarms including indications for air pressure and compressor operation, low supply pressure alarms, etc. The backup instrument air surveillance (monitoring and testing) requirements are included with the credited load(s) requirements in the Operational Safety Requirements (OSRs) for the associated system. Compliance with the OSR requirements allows the operator to confirm that the backup instrument air supply to a specific load(s) is available; see the Containment OSR, NK30-OSR-08131.02-00003 [B.13-27], as an example. Furthermore Safety Related System Tests are in place to confirm the availability of backup air supplies. As an example, see NK30-SRS-C-036 R003 [B.13-28], which is an air holding test of backup instrument air tanks 21103-TK1/2. Based on the above, the Pickering U5-8 Instrument Air system meets the intent of Section 6.6 of CSA N290.5-06.	Compliant

CSA N290.5-06 Clause	PSR2 Review	Compliant or Gap
6.7 Limiting air flow into containment *A means to limit instrument air flow into containment following DBAs shall be provided.*	Instrument air lines feeding into containment have isolation valves installed on the RAB side (upstream of the containment penetration). In the event it is required (i.e., for a LOCA), these valves can be closed to stop the air flow into containment. As examples see the instrument air lines into containment shown on the U5 flow diagrams [B.13-29] and [B.13-30]. Based on the above, the Pickering U5-8 Instrument Air system meets the intent of Section 6.7 of CSA N290.5-06.	Compliant
6.8 Normal air supply system including: 6.8.1 Compressors - including filters, compressors, motors, instrumentation & control systems, and other protective and auxiliary systems shall be rated to meet both peak air demand and reliability requirements of the system. 6.8.2 Filters and dryers - shall be capable of maintaining the instrument air quality in accordance with ANSI/ISA 7.0.01 and meet the reliability requirements of the system. 6.8.3 Air receivers – shall meet the air supply and reliability requirements of the system including air supply requirements following a loss of Class IV power until Class III power is restored.	See subsections below. The overall capacity of the compressors, dryers, filters and related equipment exceed the required firm capacity of 1970 SCFM, as stated in the Safety Report [B.13-24], as follows. Four 33% unitized instrument air compressors and associated equipment, including water cooling, rotary screw compressors and 150 kW (200 hp) motors, are rated to supply 0.307 m^3/s (650 SCFM), 860 kPa gauge (125 psig) to a common header. The header feeds four 33% twin tower air dryer units, each of 0.307 m^3/s (650 SCFM) outlet capacity, which are collectively bound by one set of dual prefilters and afterfilters, where each one, of a set of two, is capable of 0.66 m^3/s (1400 SCFM) capacity and able to remove both solid and liquid particles [B.13-22], [B.13-24]. See Clause 6.4 for further discussion on the reliability requirements of the system. As per OPG Chemistry Laboratory Procedure for Station Air Systems, P-CLP-75100-0001 R004 [B.13-26], the instrument air quality is maintained in accordance with ANSI standard ISA-S7.3 (R1981). ANSI standard ISA-S7.3 (R1981) was subsequently incorporated into ANSI/ISA–7.0.01–1996 [B.13-31]. Four main and eleven local air receivers are installed as a source of instrument air, which the Design Requirements, NK30-DR-75120-10003 R001 [B.13-23], state are capable of maintaining loads for 3 to 8 minutes upon loss of power. The Design Manual, NK30-DM-75120-00001 R000 [B.13-22], further states that, in the event of a loss of Class IV power, Class III power will be able to supply the compressors prior to depleting the instrument air and air receivers. Based on the above, the Pickering U5-8 Instrument Air system meets the intent of Section 6.8 of CSA N290.5-06.	Compliant

CSA N290.5-06 Clause	PSR2 Review	Compliant or Gap
6.9 Distribution system	See subsections below.	Compliant
6.9.1 Capability - The system shall be capable of delivering sufficient instrument air to all loads required to maintain pressure under the most severe design basis conditions and include provisions for draining moisture.	As detailed in Section 4.0 of the Design Manual NK30-DM-75120-00001 R000 [B.13-22], the instrument air distribution system is adequately designed to provide the required peak capacity to loads in the station within a pressure control range from 760 kPa (110 psi) to 860 kPa (125 psi). Backup air supply provisions are also provided to ensure operation of safety-related equipment after the most severe design basis conditions (see Clause 6.2.1). Provisions for draining include automatic drain traps to remove condensate from the main air receivers, drain valves included on every instrument air manifold and moisture provisions on the instrument air dryer units, which normally maintain the system at a dew point below minus 40°C (-40°F) [B.13-22].	
6.9.2 Header air storage tanks - shall be located and sized to allow for normal operation of the plant and safe shutdown in the event of loss of instrument air supply and shall meet air supply requirements following a loss of Class IV power until Class III power restored.	As discussed in Design Manual NK30-DM-75120-00001 R000 [B.13-22], four main and eleven local air receivers are installed as a source of instrument air, which the Design Requirements, NK30-DR-75120-10003 R001 [B.13-23], state are capable of maintaining loads for 3 to 8 minutes upon loss of power. The Design Manual, NK30-DM-75120-00001 R000 [B.13-22], further states that, in the event of a loss of Class IV power, Class III power will be able to supply the compressors prior to depleting the instrument air and air receivers. Based on the above, the Pickering U5-8 Instrument Air system meets the intent of Section 6.9 of CSA N290.5-06.	
6.10 Air supply connections to loads	See subsections below.	Compliant
6.10.1 Instrument air manifolds – shall be provided with an inlet manual isolation valve to facilitate maintenance and protect upstream supplies.	As detailed in Clause 6.1.2 all instrument air stations installed in Pickering U5-8 are provided with a shut-off root valve. These isolation points both facilitate maintenance and protect upstream supplies.	
6.10.2 [Manual] Instrument air take-off valves - shall be provided on instrument air manifolds to enable as required isolation.	As detailed in Clause 6.1.2 all instrument air stations installed in Pickering U5-8 are provided with either single or double manifolds, each having eight outlets complete with isolation valves. These isolation points both facilitate maintenance and protect upstream supplies.	

CSA N290.5-06 Clause	PSR2 Review	Compliant or Gap
6.10.3 Self-vented pressure regulating valves shall be used to regulate the air pressure of loads that do not continuously consume air and that have design pressures lower than the air system design pressure. 6.10.4 Direct connections to the distribution headers - may be permissible, via a manual isolation valve, for loads that require a large instrument air supply capacity.	The Pressure Regulating Valves (PRVs) used in the plant are typically of the self-vented type. Examples are shown in the manufacturer information included in NK30-MMM-21130-00004 R001 [B.13-32] and NICR-65640 [B.13-33]. This type of PRV is used for normal instrument air supply loads and for air supplied by compressed air bottles. The hose connections to the resin transfer system, as shown on the U5 Flow Diagram, NK30-FEH-75120-0004-U5 R018 [B.13-29], are connected to the distribution header via manual isolating valves. Based on the above, the Pickering U5-8 Instrument Air system meets the intent of Section 6.10 of CSA N290.5-06.	
6.11 Alternate air system 6.11.1 Local air storage tanks – where provided, shall be sufficient to supply air to their loads for the mission time established by the plant design documentation following loss of normal air supply. 6.11.2 Alternate air supply system – where provided, shall have sufficient redundancy to meet reliability requirements.	See subsections below. As discussed in Design Manual NK30-DM-75120-00001 R000 [B.13-22], four main and eleven local air receivers are installed as a source of instrument air which the Design Requirements, NK30-DR-75120-10003 R001 [B.13-23], state are capable of maintaining loads for 3 to 8 minutes upon loss of power. Class III power will be able to supply the compressors prior to depleting the instrument air and air receivers [B.13-22]. Backup instrument air equipment provides a seismically and environmentally qualified alternate air supply to Group 2 equipment required to operate following a DBA [B.13-23]. As described in Clause 6.2 this is accomplished by means of compressed air bottles which supply selected safety related loads for given mission times to ensure critical shutdown, cooling and containment functions are maintained, or to provide sufficient time to allow for subsequent field actions. Redundancy is further enhanced by providing independent bottles for redundant safety related components. Based on the above, the Pickering U5-8 Instrument Air system meets the intent of Section 6.11 of CSA N290.5-06.	Compliant

B.13.3 Compliance Summary for Pickering PSR2

There is one PSR2 CSA N290.5-06 (R2011) including Update No. 1 [B.13-1] gap which relates to Safety Factor 1 (Plant Design):

1. A gap exists for the Pickering Units 1,4 and 5-8 Instrument Air and Electrical Systems on Clauses 7.1 and 7.4.2 of N290.5-06 (R2011) including Update No. 1 dealing with requirements for Anticipated Operational Occurrences (AOOs). These clauses introduce the requirement for components to be qualified to perform their required functions during normal operation and AOOs. Only the portion of this clause on AOOs is pertinent to nuclear safety. It is likely that AOOs, due to their nature, do not result in a challenge to the qualification of systems, including Instrument Air and Electrical systems. However, AOOs have not been identified and analyzed in the current Pickering Safety Reports. This issue has therefore been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation.

B.14 CSA N290.6-09, "Requirements for Monitoring and Display Of Nuclear Power Plant Safety Functions In The Event Of an Accident"

B.14.1 Background

The following paraphrased from the preface and scope of CSA N290.6-09 [B.14-1] provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The monitoring and display of nuclear power plant variables following an accident are important safety functions; appropriate operator actions following such an event rely on the availability of adequate information.*
>
> *CSA N290.6 provides the requirements and recommendations for the design, manufacture, installation, and qualification of those components specifically involved in the monitoring and display of post-accident information for a nuclear reactor.*

CSA N290.6 is relevant to Safety Factor 1 (Plant Design). CSA N290.6 is not discussed in the R04 Pickering Licence Conditions Handbook [B.14-2].

CSA N290.6-09, which was reaffirmed in 2014, is the second edition of this standard, and supersedes the previous edition published in 1982 under the title "Requirements for Monitoring and Display of CANDU Nuclear Power Plant Status in the Event of an Accident" [B.14-3]. The Preface of CSA N290.6-09 [B.14-1] provides a summary of significant changes from the previous 1982 edition [B.14-3], which are discussed in Section B.14.2.2 below.

The results of PSR1 CSA N290.6 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.14.2. As identified in Reference [B.14-4], the Pickering PSR2 review of CSA N290.6-09 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- <u>Compliance:</u> Compliance indicates that the change in the safety requirement, per the topical review, is met.
- <u>Gap</u>: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.14.2 Compliance Assessment for Pickering PSR2

B.14.2.1 Application of PSR1 Review

The versions of N290.6 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

The Post Accident Monitoring (PAM) technical basis for Pickering Units 5-8 is documented in References [B.14-5], [B.14-6] and [B.14-7]. A clause-by-clause review of the Pickering Units 5-8 Critical Safety Parameter Monitoring (CSPM) and display systems design against the CSA N290.6-M82 [B.14-3] version of the Standard was documented in OPG Report NK30-REP-03680-00001 R000, "Pickering NGS-B Integrated Safety Review – Plant Design Safety Factor" [B.14-8]. NK30-REP-03680-00001 R000 [B.14-8] identified one discrepancy for Clause 5.3.1 relating to availability of instruments. This was identified as Gap 1-103, and the disposition was provided in Reference [B.14-9]. The disposition concluded that implementation of the Safe Operating Envelope (SOE) for CSPM would address the discrepancy. The implementation of SOE (including gap analysis and issue resolution) has subsequently been completed, with the compliance framework established in the CSPM Operational Safety Requirements (OSR) [B.14-6] and the CSPM OSR Compliance Table [B.14-10]. Therefore, this issue is no longer a gap for Pickering Units 5-8.

OPG Report NK30-REP-03680-00001 R000 [B.14-8] also identified three Acceptable Deviations associated with the following clauses:

- Clause 5.7.1 and Clause 5.7.3, relating to maintenance accessibility of instruments post-accident, including for calibration. These clauses were combined under Gap 1-104 and an assessment of the impact was provided in Reference [B.14-9]. It was concluded that there were sufficient instrument loops that would be accessible post-accident, there was sufficient redundancy and that calibrations for accuracy during post-accident mission were not necessary. This disposition is not impacted by Pickering NGS operation beyond 2020. Therefore, this is not a gap for Pickering PSR2.

- Clause 5.12.1, relating to separation between channelized instrument tubing. The disposition and acceptance of this gap by the CNSC is documented in Reference [B.14-11]. The disposition stated that a separate review performed for CSA N285.0, "General Requirements for Pressure-retaining Systems and Components in CANDU Nuclear Power Plants", concluded there were no gaps with respect to instrument tube routing. A separate review was also performed for CSA N285.0 as part of PSR2, and the Pickering B ISR disposition is not impacted by Pickering NGS operation beyond 2020. Therefore, this is not a gap for Pickering PSR2.

The above-mentioned Pickering Unit 5-8 Gaps and Acceptable Deviations were deemed to have either low or no safety significance as part of the Pickering B ISR, and are not impacted by Pickering NGS operation beyond 2020. Therefore, none of the above Pickering Units 5-8 ISR findings represent a Pickering PSR2 gap against CSA N290.6-M82 [B.14-3]. Pickering NGS compliance against the most recent version of the Standard, CSA N290.6-09 [B.14-1], is addressed under Section B.14.2.2 below.

Pickering Units 1, 4

The PAM technical basis for Pickering Units 1,4 is documented in References [B.14-12], [B.14-13], [B.14-14], [B.14-15] and [B.14-16]. A review of the Pickering Units 1,4 CSPM and display systems design against CSA N290.6-M82 [B.14-3] was completed in AECL Report 44RS-00531-ASD-001 R004, "Pickering A Return to Service: Review of Pickering A Design Against Current Codes and Standards (CI-007-03-01-007)" [B.14-17]. 44RS-00531-ASD-001 R004 [B.14-17] found that Pickering Units 1,4 were either fully compliant or indirectly compliant with all clauses of the standard. This review was performed prior to the implementation of the SOE or Environmental Qualification (EQ) programs at Pickering A. Subsequently, the CSPM OSR [B.14-12] and CSPM OSR Compliance Table [B.14-16] have been produced and fully implemented. Additionally, an EQ Technical Basis Document for PAM has been produced [B.14-13]. Therefore, the Pickering B ISR Gap 1-103 discussed above is also addressed for Pickering Units 1,4 and is not a PSR2 gap.

The Pickering B ISR Acceptable Deviations discussed above (related to Clauses 5.7.1, 5.7.3 and 5.12.1) were also considered for applicability to Pickering Units 1,4. CSA N290.6-M82 [B.14-3] Clause 5.7.1 was not reviewed for Pickering Units 1,4 in 44RS-00531-ASD-001 R004 [B.14-17]. However, given the similarities between plant design and instrument loop locations, the Clause 5.7.1 dispositions for Pickering Units 5-8 [B.14-9] are also applicable to Pickering Units 1,4. 44RS-00531-ASD-001 R004 [B.14-17] concluded that Clause 5.7.3 had 'Indirect Compliance', noting that "Calibration capability exists through redundant measurements." Clause 5.12.1 relates to requirements for pressure-retaining components used in the information chain and no issues were identified in 44RS-00531-ASD-001 R004 [B.14-17] relating to this clause for Pickering Units 1,4.

Based on the above, there are no PSR2 gaps associated with Pickering Units 1,4 compliance with CSA N290.6-M82 [B.14-3]. Pickering NGS compliance against the most recent version of the Standard, CSA N290.6-09 [B.14-1], is addressed under Section B.14.2.2 below.

Darlington NGS

A clause-by-clause review of Darlington NGS against CSA N290.6-M82 [B.14-3] was conducted in OPG Report NK38-REP-03680-10042-R000, "Review of CAN/CSA-N290.6-M82 (R2001) (January 1983), Requirements for Monitoring and Display of CANDU Nuclear Power Plant Status in the Event of an Accident for Darlington Integrated Safety Review" [B.14-18]. Since PSR1 reviews against CSA N290.6-M82 [B.14-3] were completed for Pickering Units 1,4 and 5-8 as discussed above, and CSA N290.6 is largely design-specific, the Darlington PSR1 results for CSA N290.6-M82 have not been assessed for applicability to PSR2.

It is noted that Darlington also conducted an ISR Code Refresh review of CSA N290.6-09 [B.14-1] in OPG Report NK38-REP-03680-10158 R000, "Code Refresh Review of CSA N290.6-2009, Requirements for Monitoring and Display of Nuclear Power Plant Safety Functions in the Event of an Accident for DNGS ISR" [B.14-19]. Although the associated findings and their resolutions were mostly specific to Darlington design documentation, NK38-REP-03680-10158 R000 has been utilized in Section B.14.2.2 below to assess Pickering NGS compliance against N290.6-09 where there is programmatically applicable content.

B.14.2.2 Application of Post-PSR1 Reviews

As identified above in Section B.14.1, the Preface of CSA N290.6-09 [B.14-1] provides a summary of significant changes from the previous edition of the Standard, N290.6-M82 [B.14-3]. These are:

a) *Harmonization with CSA N285.0 and N286.*

Compliance reviews for CSA N285.0, "General Requirements for Pressure-retaining Systems and Components in CANDU Nuclear Power Plants" and N286 "Management System Requirements for Nuclear Facilities" were completed separately as part of Pickering PSR2. Harmonization of these CSA Standards with N290.6 is largely editorial in nature and addressed via the overlapping PSR2 reviews. Therefore, there is no PSR2 gap.

b) *The addition of an informative annex on severe accidents*.

Informative Annex A, which relates to information and measurement needs for severe accidents, is non-mandatory and provided only for guidance. However, clauses identifying new build related requirements are assessed for applicability to Pickering NGS as part of PSR2. Clause A.1.1 from informative Annex A [B.14-1] states:

> *For existing plants, SAMGs* [Severe Accident Management Guidance] *should be developed with the aim of making maximum use of the existing design. For new plants, SAMGs should be considered in the design.*

SAMG parameters and associated instrumentation were not considered in the original design of Pickering NGS for Beyond Design Basis Accident (BDBA) purposes. However, as part of Fukushima follow-up activities, OPG has conducted extensive assessments for instrumentation and equipment survivability for BDBAs, including severe accidents, per Reference [B.14-20]. The review demonstrated that sufficient instrumentation has a reasonable confidence of surviving post-BDBA such that all Units could be safely stabilized in a shutdown state. Given that Annex A is non-mandatory, and the above-mentioned assessments have been conducted, there is no PSR2 gap.

c) *The addition of information to aid in the selection of parameters to be monitored.*

Clause 4 of CSA N290.6-09 [B.14-1] prescribes guidance on the selection of parameters required to assess whether the plant will continue to operate within Safety Limits following an accident. An intent review against the associated three sub-clauses (sub-clauses 4.1, 4.2 and 4.2) is discussed below for Pickering NGS:

- Sub-clause 4.1 states: "To ensure public safety following an accident, the nuclear power plant shall be monitored for verification of: (a) reactor shutdown; (b) reactor heat removal; (c) a barrier(s) to the release of radioactivity to the environment; and (d) radioactive releases."

As identified in NK38-REP-03680-10158 R000 [B.14-19], Clause 4.1 (a) (b) (c) of N290.6-09 [B.14-1] is the same as Clause 4.1.1 (a) (b) (c) of N290.6-M82 [B.14-3]. In addition, Clause 4.1 (d) in N290.6-09 is the same as Clause 4.1.2 (a) of N290.6-M82. As discussed earlier, N290.6-M82 was reviewed for Pickering Units 1,4 and Units 5-8 and the intent of theses clauses was determined to be met. Therefore, there is no PSR2 gap.

- Sub-clause 4.2 states: "Monitoring of the nuclear power plant shall include the parameters required to assess whether the plant will continue to operate within the safety limits following an accident."

  The Pickering Units 1,4 and Units 5-8 PAM technical basis and operational documentation references discussed earlier in Section B.14.2.1 describe the CSPM indications of important parameters at designated operating locations, as well as qualified instrumentation loops. Per the Pickering B CSPM OSR [B.14-6]:

  > *CSP Monitoring forms the minimum set of post accident monitoring activities that must be carried out in order to meet the safety objective of protecting the public. In this context, it is important to note that Critical Safety Parameters are the parameters that must be maintained within safety limits in order to ensure that the Control, Cool, and Contain safety functions are being continually satisfied post-accident. Critical Safety Support Parameters (CSSPs) are parameters required to determine the appropriate restoration procedure to be followed given one or more CSPs are in an unacceptable range. Support Parameters give advance warning that a CSP may reach its action limit but they might not be available following a Design Basis Earthquake (DBE). CSP monitoring is no longer required when it has been determined that the reactor is adequately controlled (shutdown), cooled (Heat Transport System (HTS) is subcooled), and contained (radioactivity remains within containment). If a subsequent event occurs that could challenge any of these critical parameters, CSPM will be reintroduced…*
  >
  > *Critical Safety Parameter Monitoring instrumentation is required to provide necessary indications following all design basis accidents, including situations where the cause and course of the accident may be indeterminate. The indications are provided in the Main Control room (MCR); and should the MCR become uninhabitable, necessary CSPM indications are provided in the Unit Emergency Control Centres (UECCs).*

  Similar statements are made in the Pickering A CSPM OSR [B.14-12]. CSPM indications are provided in the MCR and the Shutdown System Enhancement Instrumentation Rooms. Based on the above, Pickering NGS meets the intent of sub-clause 4.2.

- Sub-clause 4.3 states: "Monitoring shall be performed for evaluating radiological conditions (a) to determine when conditions are developing that warrant initiating off-site emergency procedures; and (b) that warrant the initiation of off-site emergency procedures."

As identified in NK38-REP-03680-10158 R000 [B.14-19], Clause 4.3 (a) of N290.6-09 [B.14-1] is the same as Clause 4.1.2 (a) of N290.6-M82 [B.14-3]. N290.6-M82 was reviewed for Pickering Units 1,4 and Units 5-8, as discussed earlier, and the intent of this clause was determined to be met. The same conclusion is applicable to PSR2.

The radiation monitoring that is required in the event of a radiation emergency is used to support decisions regarding off-site actions as part of the emergency response framework. Monitoring within the plant is provided by the Automated Source Term Gamma Monitoring System, portable monitors and stack monitoring. Offsite radiation monitoring is provided by the Automated Near Boundary Gamma Monitoring System and dosimeters. Therefore, Pickering is compliant with the requirements of this clause.

Based on the above, Pickering NGS meets the intent of CSA N290.6-09 [B.14-1] and there are no PSR2 gaps.

B.14.3 Compliance Summary for Pickering PSR2

There are no PSR2 gaps for CSA N290.6-09 [B.14-1]. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with CSA N290.6-09.

B.15 CSA N290.11-13, "Requirements for Reactor Heat Removal Capability During Outage of Nuclear Power Plants"

B.15.1 Background

The following, paraphrased from the preface and scope of CSA N290.11 [B.15-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of CSA N290.11 is to ensure that the designs of all water-cooled nuclear power plants include systems that transfer heat from the reactor to the ultimate heat sink during outages.*
>
> *CSA N290.11 sets the requirements for the design, qualification, installation, commissioning, operation, maintenance, testing, inspection, and documentation requirements for systems providing heat removal from the reactor core to the ultimate heat sink(s) for water-cooled nuclear power plants during outages. CSA N290.11 covers only fuel cooling within the reactor core and does not cover spent fuel pool cooling, off-reactor fuelling operations, or the completely defueled core state.*

All of N290.11-13 is directly relevant to Safety Factor 1 (Plant Design).

CSA N290.11-13 is the first edition of this standard. Compliance with N290.11 is not currently a licence requirement for Pickering NGS (PROL 48.02/2018) and is not referenced in the Pickering Licence Conditions Handbook [B.15-2].

As identified in Reference [B.15-3], the Pickering PSR2 review of CSA N290.11-13 is a High Level Review. For a PSR2 High Level Review, the degree of conformance with clauses or groups of clauses in the Law, Regulation, Code or Standard (L/R/C/S) is demonstrated by supporting evidence stating whether the intent of the requirements stipulated in the requirement document is met. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the intent of the safety requirement is met.
- Gap: A Gap indicates that the intent of the safety requirement is not met.

B.15.2 Compliance Assessment for Pickering PSR2

B.15.2.1 Application of PSR1 Reviews

There have not been any programmatic or system/application PSR1 reviews against CSA N290.11 for Pickering or Darlington.

B.15.2.2 Application of Post PSR1 Reviews

The CSA Publication Notice for N290.11-13 [B.15-4], identifies the following Summary of Impacts of the significant features of this standard:

1. Defines and uses the term "process heat sink" instead of "primary/back-up heat sinks".

2. Provides high level reliability requirements for the design of outage heat sinks.

3. Provides testing requirements, including the requirements to test standby heat sink systems during the outage.

4. Clarifies that work can be done on a primary heat sink.

As discussed above, a compliance review of CSA N290.11-13 was not undertaken as part of previous PSR1 reviews and the following High Level assessment has been completed. In the review below, the degree of conformance with clauses or groups of clauses in the L/R/C/S is assessed for Pickering NGS by reference to supporting evidence stating whether the intent of the requirements stipulated in the L/R/C/S is met (Note: Introductory Sections 1 through 3 do not contain requirements and are not included).

CSA N290.11-13 Clause	PSR2 Review	Compliant or Gap
4.1 Functional Requirements - General	The general requirements for heat sink management are contained in N-STD-OP-0025 [B.15-5], Sections 1.1 and 1.2. These contain the requirements stated in Section 4.1. Monitoring of heat sink effectiveness is covered in section 1.4 of [B.15-5] and in the Pickering Units 5-8 and Units 1,4 Shutdown Heat Sinks Operating Manuals [B.15-6] and [B.15-7].	Compliant
4.2 Functional Requirements - Success Criteria	Section 1.2 of [B.15-5] provides the capability requirements and acceptance criteria for both shutdown and emergency heat sinks in compliance with this section.	Compliant
5.1.1 to 5.1.5 Heat Sink Requirements - General	The heat sink standard [B.15-5], Section 1.5.3 prescribes that no "normally anticipated single failure" can fail both the primary and back-up heat sink. N-STD-OP-0025 [B.15-5] also requires: 1. that process and emergency heat sinks be specified in advance; 2. that heat sink strategies consider defence in depth and reliability in the specification of back-up heat sinks; 3. Special considerations for conditions which could affect Heat Transport System (HTS) boundary integrity, e.g. ice plugs. The requirement for back-up heat sinks to mitigate the conditions following an Anticipated Operational Occurrence (AOO) is not specified in governance or procedures. Loss of a division of power, a single component failure, etc., which are likely to be considered in the set of AOOs, are accounted for in the specification of heat sinks. However, AOOs have not been identified	Gap **<u>PSR2 CSA N290.11-13 Gap #1</u>**

CSA N290.11-13 Clause	PSR2 Review	Compliant or Gap
	and analyzed in the current Pickering Safety Reports, and demonstration of heat sink capability following an AOO has not been formally addressed for Pickering. Therefore, this issue is identified as **PSR2 CSA N290.11-13 Gap #1.**	
5.1.6 Heat Sink Requirements - General	The Pickering Units 5-8 and Units 1,4 Shutdown Heat Sinks Operating Manuals [B.15-6] and [B.15-7] specify all of the requirements listed in this section.	Compliant
5.1.7-5.1.8 Application of Single Failure Criterion	For a new nuclear plant, this clause requires that the emergency heat sinks shall meet the single failure criterion. For existing plants (Clause 5.1.8), this is not mandatory. The designated outage emergency heat sinks, as per Reference [B.15-8] are: • Pickering 1,4: Emergency Coolant Injection System (ECIS) and Emergency Boiler Water Supply (EBWS), supported by the Interstation Transfer Bus (ISTB) and Class III standby generators; ECI recovery for HTS open or HTS leaks/Loss of Coolant Accident (LOCA). Additionally, for a seismic event, Shutdown Cooling (SDC) is credited. • Pickering 5-8: ECIS and Emergency Water Supply (EWS), supported by Emergency Power Supply (EPS). A gap relating to the single failure criterion was identified during the Pickering B Integrated Safety Review (ISR) [B.15-9]. This gap was categorized as an acceptable deviation that would be confirmed when the updated Pickering 5-8 Probabilistic Safety Assessment (PSA) was complete. The PSA update was subsequently completed and this issue has since been closed in the Continued Operations Plan [B.15-10]. Both Pickering 5-8 and 1,4 now have outage PSAs which model the above systems, identify dominant contributors to plant risk and significant singletons. The outage plant risk for both Pickering 5-8 and 1,4 has been demonstrated to be acceptable. Hence, the rationale for closure of the Pickering B PSR1 gap is also applicable to outage heat sinks and to Pickering 1,4.	Compliant
5.1.9 to 5.1.12 Heat Sink Requirements - General	The primary and back-up heat sinks for Units 1,4 and 5-8 are identified in [B.15-6], [B.15-7]. They do not rely on safety system initiation and do not impact on the reliability of engineered safety features in the plant.	Compliant

CSA N290.11-13 Clause	PSR2 Review	Compliant or Gap
	The requirements for demonstrating heat sink capability are identified in Section 1.2.2 of [B.15-5]. The emergency heat sinks used at Pickering, the boilers supplied by water from either the EWS, i.e. Group 2 for Units 5-8 and the EBWS for Units 1-4, have redundancy by design.	
5.2.1 Heat Sink Operation - General	N-STD-OP-0025 [B.15-5] defines general requirements and requires that heat sink management be under control of qualified, licensed staff.	Compliant
5.2.2.1 to 5.2.2.8 Heat Sink Operation - Recall	Sections 1.2.2 of [B.15-5] defines the basic requirements for back-up and emergency heat sink recall times. Further detailed requirements and practical considerations are contained in Section 1.3.1, including the requirement to ensure recall times can be achieved by careful work planning, considering conditions when implementing the back-up/emergency heat sink and ensuring there is margin in the required recall times. It also requires a test of the recall strategy where a significant recall margin does not exist (Section 1.3.1 (c) (2) (iii)). For Units 1,4 Section 4.2 of [B.15-6] and 4.2.4 of [B.15-7] for Units 5-8, document the process for calculating and documenting heat sink recall times.	Compliant
5.2.2.9 to 5.2.2.13 Heat Sink Operation - Recall	There are approved procedures for implementing back-up and emergency heat sinks. They have been devised to make use of available engineered heat sinks and methods of circulation which minimize the use of manual actions, most of which are completed from the Main Control Room (MCR). The consequences of failure of not placing a heat sink in service prior to the recall time have been assessed in the Safety Report. Emergency Operating Procedures are written to address a loss of heat sink. Recall times are calculated in Section 4.2 of [B.15-6] for Units 1,4 and 4.2.4 of [B.15-7] for Units 5-8 and take into account all relevant factors, i.e. monitoring, operator actions and other activities. The estimated time to change between various heat sinks is contained in the operating procedures.	Compliant
5.2.3 Heat Sink Operation - Actions on Failure of a Heat Sink	Section 1.6 of [B.15-5] prescribes actions that must be taken in the event of failure of process heat sinks. It details actions to take such as:	Compliant

CSA N290.11-13 Clause	PSR2 Review	Compliant or Gap
	• If failure of any heat sink occurs, work that could adversely affect the other two heat sinks shall be suspended immediately, e.g. the back-up and emergency heat sinks. • Highest priority is given to establishing a primary and back-up heat sink configuration meeting the requirements of [B.15-5]. • If both process heat sinks fail, all work affecting the emergency heat sink shall be suspended. Highest priority shall be given to re-establishing process heat sinks and preparation for implementing the emergency heat sink is also high priority. Section 5.0 of References [B.15-6] and [B.15-7] contain the detailed procedures prescribing the actions to take following process heat sink failures required by this section.	
5.2.4 Heat Sink Operation - Heat Sinks Affecting Other Work	Section 1.3.3 of P-INS-03600-00002, "Reference Guide for Reactor Safety Support of Outages" [B.15-8] outlines the process used for conducting reactor safety assessment during outages. Section 1.3.6 of this instruction describes the process followed to: • *Identify of any vulnerabilities resulting from combinations of reduced coolant inventory operation, electrical power alignments, safety system unavailability, heat sink transitions, and other abnormal system alignments.* • *Identify the need for contingency plans to mitigate the effects of an unexpected loss of function of systems maintaining shutdown safety, or heat sink function.* • *Identify the need for training and incident prevention actions to reduce risk during periods of vulnerability, when needed.* This work is performed prior to and during outages to assess heat sink and other reactor safety issues that could be affected by planned and emergent work. In addition, Section 1.2.2 (a) prescribes that special consideration be given to conditions that affect HTS integrity or relief capability, including fuel channel work, which may affect heat sink capability and recall time.	Compliant

CSA N290.11-13 Clause	PSR2 Review	Compliant or Gap
5.2.5 Heat Sink Operation - Monitoring	Section 1.4 of [B.15-5] contains the requirements for heat sink monitoring, prescribing that sufficient monitoring of reactor heat sinks shall be provided to ensure there is timely indication or warning of degradation in heat sink capability. In addition, a heat sink checksheet is used at the stations, e.g. P-FORM-10308 [B.15-11] for Units 1,4 and P-FORM-10216 [B.15-12] for Units 5-8, to routinely monitor the status of outage heat sinks and their effectiveness. HTS temperature, pressure, flow, level (if in a drained state) and D_2O storage level and cover gas pressure are monitored to ensure in-service heat sink effectiveness. Status of the back-up and emergency heat sinks are also reviewed in the form.	Compliant
5.3 Instrumentation and Control	A number of parameters using directly connected instrumentation, measure heat sink effectiveness. Trends are set-up for monitoring twice per shift, e.g. HTS temperatures, see section 4.1.4 of [B.15-7]. To provide the Authorized Nuclear Operator with enhanced monitoring when Shutdown Cooling is valved in as part of a heat sink, temperature alarm setpoints on all Shutdown Cooling Heat Exchanger inlet temperature elements are lowered to 5 degC above the current HTS temperature. This allows for early warning of HTS temperature increases (see Section 4.1.4 of [B.15-7]). For other heat sinks, alarms occur on failure of the equipment resulting in the loss of heat sink, e.g. HTS pump failure, failure of a service water pump, or other supporting component failure. Neutronic power trips are in place for heat sinks while not in the Guaranteed Shutdown State, as well as for some heat sink combinations while in a Guaranteed Shutdown State.	Compliant
5.4 Containment Boundary	This requirement is addressed in the PSR2 CSA N290.3 code review.	Compliant
5.5 Loop Isolation	The clauses identify that if loops are isolated, then they should be treated independently, in terms of heat sink requirements. Pickering HTS loops are usually isolated for outage heat sinks and the same type of heat sink is used for both HTS loops. This is done to simplify management of the heat sink strategy. The credited heat sinks in each loop ensure adequate cooling.	Compliant

CSA N290.11-13 Clause	PSR2 Review	Compliant or Gap
5.6.1 Reliability - General	There is a requirement that a design reliability be established for each outage heat sink. The process heat sinks used during outages have been designed to remove heat while the reactor is at higher thermal power conditions. The main process heat sink designed for shutdown states is the Shutdown Cooling System, though additional systems (e.g., air conditioning units, boilers/Steam Reject Valves (SRVs), boiler blowdown, bleed cooler) are credited as outage heat sinks, and meet the quality requirements for their application. The emergency heat sinks used at Units 1,4 and Units 5-8, i.e., EBWS and EWS respectively, are the same as those credited for higher power operations. The reliability target exists for Systems Important to Safety per Reference [B.15-13] and the on-demand (i.e., standby for HTS cooldown) unavailability targets for SDC at both stations is included in the Annual Reliability Report [B.15-14]. For Pickering 5-8, the SDC (in normal heat sink mode) unavailability requirements were established in the Safety Design Matrix (SDM) Study [B.15-15]. Although, no formal SDM study was completed for Pickering A, the SDC systems have a very similar configuration between the two stations. Assessment of outage heat sink unavailability is completed as part of outage risk management planning per [B.15-16] from an instantaneous, integrated plant perspective. Although reliability targets are established for some outage heat sinks (e.g., SDC), other credited outage heat sinks do not have a design unavailability or reliability. This issue relating to heat sink design reliability for Pickering Units 1,4 and 5-8 is identified as **PSR2 CSA N290.11-13 Gap #2.** Reliability of all outage heat sinks (including those without explicit targets) is managed through the Risk and Reliability Program (both through unavailability models as well as through PSA), hence the reactor safety impact is assessed and monitored. This clause also has a requirement that the designed reliability for process heat sinks be consistent with the AOO frequency limits (i.e., the emergency heat sink should not be relied on for an AOO). This cannot be verified because the AOO events relating to outage heat sinks have not been identified or analyzed in the current Pickering Safety Reports. However, as described above, heat sink configuration reliability (fuel and core damage frequency) is assessed as part of integrated outage risk monitoring [B.15-16], the results of which are input to	Gaps **PSR2 CSA N290.11-13 Gap #2** **PSR2 CSA N290.11-13 Gap #3**

CSA N290.11-13 Clause	PSR2 Review	Compliant or Gap
	ongoing outage decision-making based on established criteria. This issue relating to heat sink design reliability being required to be consistent with AOO frequency is identified as **PSR2 CSA N290.11-13 Gap #3.**	
5.6.2 Reliability Analysis	Risk models have been developed to enable the tracking of outage risk [B.15-16], [B.15-17].	Compliant
5.6.3 Redundancy	Redundancy for single failures is provided by having primary and back-up heatsinks rather than having redundancy for single failures within a heat sink. Redundancy for the Ultimate Heat Sink to the lake or atmosphere is always provided either via multiplicity of heat exchangers rejecting heat to service water or boilers and SRVs to the atmosphere.	Compliant
5.6.4 Reliability - Diversity	Section 1.5.1 of [B.15-5] requires diversity between primary and back-up heat sinks. Where diversity is not possible, the probability of consequences of losing both heat sinks shall be assessed as being acceptable. The outage reactor safety assessment performed as part of Reference [B.15-8] addresses this. Both Pickering Units 1,4 and 5-8 have a number of heat sinks that are diverse and can be used under different HTS conditions.	Compliant
5.7 Independence and Separation	Section 1.5.1 of [B.15-5] requires independence between the primary and back-up heat sinks. It specifies among other requirements that there shall be no normally anticipated single failures that could fail both the primary and back-up heat sinks. Section 1.5.2 of [B.15-5] specifies the requirement that the emergency heat sink be independent from the process heat sinks. For both Units 1,4 and 5-8 the Operating Manuals contain requirements for primary and back-up heat sink independence, e.g. section 4.3.3 in Reference [B.15-6]. Heat sink tables are provided in the Operating Manuals (e.g. Section 4.2.1 in [B.15-7]), which specify permissible combinations of heat sinks, based on independence and other relevant factors. Separation requirements are met in part by ensuring independence between heat sinks. In addition, primary heat sink equipment and components are designated and	Compliant

CSA N290.11-13 Clause	PSR2 Review	Compliant or Gap
	protected with signs and barriers as required per P-INS-09000-00003, "Protected Equipment Zones" [B.15-18]. Separation between process heat sinks and emergency heat sinks at Pickering is assured by providing an emergency heat sink that is Group 2 in Units 5-8, and EBWS for Units 1,4 (supplied by Units 5-8 service water pumps and power supplies).	
5.8 Pressure-retaining SSCs	The requirement of this section is addressed separately in the PSR2 code review for CSA N285.0.	Compliant
5.9 Environmental Qualification	Equipment required to function after a DBA in the outage unit is environmentally qualified per the requirements of N-PROG-RA-0006, "Environmental Qualification" [B.15-19]. A separate PSR2 code review has been prepared for CSA N290.13. The requirement on seismic qualification is met by having emergency heat sinks capable of withstanding the impact of a Design Basis Earthquake. The seismic heat sink for Units 5-8 is specified in Section 4.3.4 in [B.15-7] and in Section 4.4.2.2 in [B.15-6] for Units 1,4. Aging Management requirements are addressed in N-PROG-MP-0008, "Integrated Aging Management" [B.15-20].	Compliant
5.10 Dynamic Piping Effects	The requirements of this section are met by having emergency heat sinks at Pickering that are separate from the process heat sinks, i.e. Group 2 in Units 5-8 (EWS), and EBWS for Units 1,4 (supplied by Units 5-8 service water pumps and power supplies).	Compliant
5.11 Maintenance	Section 1.3.1 (b) and (c) of Reference [B.15-5] provide the requirements for allowable work and processes to follow on primary and back-up heat sinks. For example, Section 1.3.1 (b) only permits cursory work be performed on the primary heat sink. Section 1.3.1 (c) provides a number of requirements for allowable work on back-up heat sinks, e.g. work on back-up heat sink components requires the component to be placed in a safe state. Section 1.3.1 (d) of [B.15-5] contains requirements for maintenance work on the emergency heat sink. Pickering Units 1,4 Operating Manual [B.15-6] Section 4.5 and Units 5-8 Operating Manual [B.15-7] Section 3.4.1.1 contain additional detailed requirements associated with	Compliant

CSA N290.11-13 Clause	PSR2 Review	Compliant or Gap
	maintenance work on heat sinks. These references address all of the requirements of Section 5.11 of CSA N290.11. In addition, Reference [B.15-8] on Reactor Safety support of outages assesses the risk posed by work performed on outage heat sinks and other outage scope to ensure public safety risk is acceptable.	
5.12 Functional Testing	The heat removal capabilities of the Pickering heat sinks have been assessed and the applicable limits are contained in the Pickering Operating Manuals, for example, Section 4.1.1 in [B.15-7]. Generally, the process heat sinks are designed for much greater heat removal during higher power operation, e.g. boilers/Steam Reject Valve, shutdown cooling. Testing and verification requirements for process heat sinks are outlined in Operating Manuals for Units 1,4 in Section 3.4.12 [B.15-6] and Section 3.4.15 for Units 5-8 [B.15-7]. Testing for transfers from one heat sink to another is outlined in Section 7.0 of the Operating Manuals; supplementary Operating Procedures are referenced in Section 10 of the OMs and in various parts of Section 4 and 5 of the OMs. Confirmation of heat sink function and performance is by completion of the heat sink checklists ([B.15-11], [B.15-12]) and confirming conditions are acceptable. Section 1.3.1 of [B.15-5] requires post-maintenance testing of any work done on a credited heat sink prior to it being placed in-service. A separate PSR2 code review of CSA N290.0 has been performed.	Compliant
5.13 Documentation	Documentation of requirements for heat sinks and operating procedures for their implementation are covered in References [B.15-5], [B.15-6] and [B.15-7].	Compliant
5.14 Heat Sink Support System Requirements	Requirements for systems used to support heat sink operation are generally the same as for the process heat sink, e.g., electrical system independence. A separate PSR2 code review has been prepared for CSA N290.5 on support systems.	Compliant

B.15.3 Compliance Summary for Pickering PSR2

There are three PSR2 CSA N290.11-13 gaps which relate to Safety Factor 1 (Plant Design):

1. The CSA N290.11-13 Clause 5.1.1 to 5.1.5 requirement for back-up heat sinks to mitigate the conditions following an Anticipated Operational Occurrence (AOO) is not specified in governance/procedures. Loss of a division of power, a single component failure, etc., which are likely to be in the set of AOOs, are accounted for in the specification of heat sinks. However, AOOs have not been identified and analyzed in the current Pickering Safety Reports. This issue is therefore a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation.

2. Clause 5.6.1 of CSA N290.11-13 requires design reliability to be established for outage heat sinks. Although some emergency heat sinks (e.g., Emergency Boiler Water Supply and Emergency Water Supply) have design reliability requirements, design reliability requirements have not been established for all normal and back-up heat sinks used at Pickering. Reliability of all outage heat sinks (including those without explicit targets) is managed under the Risk & Reliability Program (both through unavailability models as well as through Probabilistic Safety Assessment), hence reactor safety impact is assessed and monitored. However, there is a PSR2 gap with respect to establishment of design reliability requirements for Pickering Units 1,4 and 5-8 outage heat sinks.

3. Clause 5.6.1 of CSA N290.11-13 requires that the designed reliability for process heat sinks be consistent with AOO frequency limits, such that an emergency heat sink does not need to be used for an AOO. AOOs have not been identified and analyzed in the current Pickering Safety Reports. This issue is therefore a PSR2 gap and is being addressed as part of REGDOC-2.4.1 implementation.

B.16 CSA N290.14-15, "Qualification of Digital Hardware and Software for Use in Instrumentation and Control Applications for Nuclear Power Plants"

B.16.1 Background

The following, paraphrased from the preface and scope of CSA N290.14-15 [B.16-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of CSA N290.14 is to establish a qualification process for digital instrumentation and control systems and components for use in nuclear power plants [NPPs] and provides guidance for maintaining qualification once it has been established. It addresses application-specific qualification by outlining a set of qualification concerns and failure modes that allow candidate products to be assessed within the context of their application.*
>
> *This standard does not apply to business systems (e.g., business applications, desktop computers, email, business networks), analysis software (e.g., scientific, engineering, and safety analysis software), or passive devices (e.g., wires), unless they are part of a safety-related computing system.*

CSA N290.14-15 is applicable to Safety Factor 1 (Plant Design).

Compliance with CSA-N290.14 is not currently a licence requirement for Pickering NGS (in accordance with PROL 48.02/2018) per the R04 Pickering Licence Conditions Handbook [B.16-2]. CSA N290.14-15 is the second edition of this standard, and supersedes the previous edition published in 2007 (and reaffirmed in 2012) [B.16-3] under the title "Qualification of Pre-Developed Software for Use in Safety-Related Instrumentation and Control Applications in Nuclear Power Plants". The publication notice for the new edition, [B.16-4], identifies the following significant changes from the previous edition:

1. *Expanded scope to include all aspects of digital hardware and software qualification. The user has new guidance for qualification of all aspects of the digital product. This includes custom software, pre-developed software, digital hardware, and software engineering tools.*

2. *The addition of the term digital items (custom software, pre-developed software, digital hardware, and software engineering tools). An informative annex is also added in this standard to give examples of how to identify digital items in a candidate product.*

3. *Added integration concerns of digital items in Annex. This informative annex reflects industry OPEX and best practices when dealing with digital upgrades in the nuclear power plants.*

4. *Added proof through testing as a qualification option for pre-developed software. The proof through testing method may be applied to pre-developed software digital items that are unmodified, and are to be used in Category 3 applications. This adds flexibility for the qualification process when no other method can be used to qualify the*

candidate product. This method is meant for low complexity products that run with discrete executions or used continuously while the system is online and that the manufacturer is not willing to provide information on how the product was developed (e.g. boot firmware, disk controllers, etc.).

5. *Added an informative annex on how to qualify software engineering tools. Software engineering tools used for the configuration, maintenance of digital items, or the development of custom software will now require qualification.*

6. *Guidance regarding emerging I&C [Instrumentation & Control] technology applications [Field Programmable Gate Arrays (FPGA) and Wireless]. Users are required to develop a wireless co-existence management plan and application policy for the use of wireless safety-related applications. Users should proceed with thoughtfulness to ensure the use of wireless systems uphold defense in depth, reliability and security requirements. Capital investment and maintainability costs for the usage of wireless technology may be considered high (>1M) based on lack of industry for safety related applications and OPEX [Operating Experience]. Users are given guidance on the qualification expectations for FPGA applications. FPGAs are required to be qualified with respect to both hardware and software.*

7. *The recognized program list has been updated. Some utility processes which reference withdrawn programs will have to be revised.*

The publication notice further notes that the revised standard reflects current practice at Bruce Power, OPG, and Candu Energy, and does not add new demands on these users [B.16-4].

As identified in Reference [B.16-5], the Pickering PSR2 review of CSA N290.14-15 is a High Level review. For a PSR2 High Level review, the degree of conformance with clauses or groups of clauses in the Law, Regulation, Code or Standard (L/R/C/S) is demonstrated by supporting evidence stating whether the intent of the requirements stipulated in the requirement document is met. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the intent of the safety requirement is met.
- Gap: A Gap indicates that the intent of the safety requirement is not met.

B.16.2 Compliance Assessment for Pickering PSR2

B.16.2.1 Application of PSR1 Reviews

There have not been any programmatic or system/application PSR1 reviews against CSA N290.14 for Pickering or Darlington.

B.16.2.2 Application of Post PSR1 Reviews

The 2007 version of N290.14-07 (R2012) [B.16-3] was introduced into OPG governance in 2009 (i.e., Revision 4 of N-PROC-MP-0049, "Procurement of Software and Products Containing Software" [B.16-6]). Hence, it was not possible for software procured prior to this time to be directly compliant with N290.14. Software applications introduced into safety related systems prior to 2009 were qualified in accordance with OPG governance based on industry standards such as those developed by CANDU Computer Systems Engineering Centre of Excellence, CANDU Owners Group (COG) and International Electrotechnical Commission (IEC).

Qualification of Legacy Systems

This code review needs to consider the level of compliance for systems and applications that are within the scope of the PSR. This is defined in PSR2 Basis Document [B.16-5], Tables B1 and B2. Pickering Units 1, 4 and Pickering Units 5-8, have several legacy installations with Real-Time Process Computing (RTPC) on Safe Operating Envelope (SOE) systems and Systems Important to Safety (SIS) that are included in the PSR2 Assessment Basis [B.16-5], Tables B1 and B2, that pre-date the adoption of N290.14.

Examples of applications that have received formal software categorization, but pre-date the adoption of CSA N290.14-07 in 2009 include:

- Critical Safety Parameter displays
- Data Extraction Systems
- Various microprocessor controllers used in Fuel Handling, Boiler Level Control, Class III/II/I power distribution, Standby Generator control and test loops.

It is difficult to retroactively qualify these applications to N290.14. The qualification of these systems was based on the best-industry practice of the day and is supported by extensive operating experience and successful proven in-service application over many years.

Further, recent correspondence with the CNSC [B.16-7] identifies all of the software application qualifications for software Categories 1, 2 & 3 from January 1, 2007 to the time of the correspondence (June 2016), noting that software qualification in accordance with N290.14-07 was not integrated into OPG governance before May of 2009. Therefore, for any systems containing pre-developed software that were modified after 2007, there is evidence of software qualification per Reference [B.16-7]. In addition, any modifications of RTPC custom software for pre-existing systems are performed per N-PROG-MP-0006 [B.16-8], which outlines qualification requirements in accordance with N290.14-07.

An evaluation of legacy Real-Time Process Computing applications with respect to the requirements of N290.14-15 for Categories 1, 2 & 3 software has not been performed. This is identified as a PSR2 gap (**PSR2 N290.14-15 Gap #1**).

High Level Code Review

As discussed above a compliance review of CSA N290.14-15 was not undertaken as part of previous PSR1 reviews and, therefore, the following High Level assessment has been completed. In the review below, the degree of conformance with clauses or groups of clauses in the L/R/C/S is assessed for Pickering NGS by reference to supporting evidence stating whether the intent of the requirements stipulated in the L/R/C/S is met. The High Level review below assesses the degree of conformance of OPG's current governance and procedures with respect to N290.14, independent of specific applications.

N290.14-15 Clause	PSR2 Review	Compliant or Gap
0. Introduction	No requirements specified	N/A
Figure 1 Process flow diagram	No requirements specified	N/A
Scope	No requirements specified	N/A
1.1 This Standard defines requirements for the process of qualification of digital hardware and software for use in instrumentation and control applications for NPPs. **Notes:** **1)** *This Standard applies to individual safety-related programmable digital devices containing software or programmable logic (e.g., devices such as application-specific integrated circuit (ASICs), complex programmable logic device (CPLD), and field-programmable gate array (FPGAs)).* **2)** *This Standard may provide guidance for nuclear facilities other than NPPs, using a graded approach.*	The OPG governance relating to software N-PROG-MP-0006, "Software" [B.16-8], does not explicitly identify that it is applicable to digital hardware. However, digital hardware is addressed via a combination of N-PROG-MP-0009, "Design Management" [B.16-9], N-PROG-MP-0001, "Engineering Change Control" (ECC) [B.16-10], and Software [B.16-8] programs. Hardware is explicitly addressed in OPG design standards required by the implementing procedures for these OPG programs. These standards include N-STI-69000-10013, "Computer System Requirements and Design" [B.16-11] and N-STI-69000-10005, "Category II/III Software Testing" [B.16-12]. OPG governance does not reference the 2015 version and only refers to the 2007 version of the Standard. However, since N290.14-15 is not currently a licensing requirement, this is not a PSR2 gap.	Compliant
1.2 This Standard refers directly to other industry standards for topics related to the categorization of functions, hardware qualification aspects, and software qualification aspects.	No requirements specified	N/A
1.3 This Standard does not apply to business systems (e.g., business applications, desktop computers, email, business networks), analysis software (e.g., scientific, engineering, and safety analysis software), or passive devices (e.g., wires), unless they are part of a safety-related computing system. **Note:** *For requirements related to analysis software refer to CSA N286.7.*	No requirements specified	N/A

N290.14-15 Clause	PSR2 Review	Compliant or Gap
1.4 Annex E, provides guidance that focuses on activities unique to the integration of a digital item, based on recent best practice and operating experience. **Note:** *Refer to CSA N290.12 for integration concerns with respect to human factors.*	No requirements specified	N/A
1.5 This Standard assumes that the candidate product has been previously assessed as functionally suitable for the proposed application. **Note:** *Functional suitability is a determination of the degree to which a product can meet the specified requirements including confirmation that the use of the digital item does not conflict with the requirements of the application. This Standard is* ***used to qualify the product*** *after this determination is made.*	The Software [B.16-8], Design Management [B.16-9], Configuration Management [B.16-13], and ECC [B.16-10] programs ensure a suitable product is procured. N-PROC-MP-0049, "Procurement of Software and Products Containing Software" [B.16-14], addresses this for new installations and component replacements.	Compliant
1.6 In this Standard, "shall" is used to express a requirement, i.e., a provision that the user is obliged to satisfy in order to comply with the standard; "should" is used to express a recommendation or that which is advised but not required; and "may" is used to express an option or that which is permissible within the limits of the Standard…	N/A - Clarification	N/A
2. Referenced publications 3. Definition and Abbreviations 4. Referenced requirements	N/A – no requirements	N/A
5. General requirements	Heading only	N/A
5.1 Definition of candidate product scope The scope of the candidate product shall be clearly identified, including the following: a) clear definition of which components are included and which are not; b) description of applicable functions, including safety functions, implemented by the candidate product; c) description of applicable system interfaces; and	As part of N-PROC-MP-0090, "Modification Process" [B.16-15], N-FORM-10959, "Design Scoping Checklist" [B.16-16] is completed. Section 2.7 of N-FORM-10959 directs the preparer to identify RTPC implications for the design change. If there is RTPC software involved in the change, N-PROG-MP-0006 will require either procedure N-PROC-MP-0099, "Development of Real-time Process Computing Systems" [B.16-17] or N-PROC-	Compliant

N290.14-15 Clause	PSR2 Review	Compliant or Gap
d) identification of any restrictions or conditions related to the use of the candidate product in the proposed NPP application. Note: *Typically the candidate product is part of a larger system. It is important therefore to define the scope that is to be considered as part of the qualification activities.*	MP-0049, "Procurement of Software and Products Containing Software" [B.16-14], to be followed. The bulleted requirements are addressed in the Computer System Requirements (CSR) and Computer System Design (CSD) in accordance with N-STI-69000-10013, "Computer System Requirements and Design" [B.16-11].	
5.2 Categorization of the function 5.2.1 Functions that are intended to be implemented by the candidate product shall be identified and assigned a safety category in accordance with a standard selected from the reference standards given in Table 1. The safety category of the proposed application shall be determined using the most safety-significant function.	The details provided in Table 1 of CSA N290.14-15 are the same as those detailed in OPG Standard, N-STI-69000-10000, "Software Categorization" [B.16-18]. Note, the categorization in this standard does not apply to hardware requirements.	Compliant
5.3 Personnel qualification The personnel performing a qualification shall collectively demonstrate a) experience in computer engineering (which includes software and hardware),and quality assurance (QA) as they pertain to safety-related instrumentation and control (I&C) applications in NPPs; b) familiarity with relevant standards; and c) an understanding of the target application's impact on safety actions and safety improvements.	a) This qualification and expertise resides under the "Computers and Control Design Department" under the Nuclear Engineering organization. All training requirements and qualifications are maintained in the Training Information Management System (TIMS) II. The core and supplementary training for Engineering support is documented in, N-TQD-403-00001, "Nuclear Engineering Support Personnel Training and qualification Description" [B.16-19]. Additional qualification requirements are documented in N-QA-403-00008 R009, "Nuclear Design Engineering Qualification Guide" [B.16-20]. In addition to the core training, Appendix B of N-TQD-403-00001 identifies the Program Element (PEL) ID 65690, "Real-Time Computer Based Systems and Software Governance – CAL" [B.16-19]. Appendix A of N-QG-403-00008 specifies specific duty area training for staff in the Computers and Control Design Department, including PEL ID 28963, "DE Computer Evaluation – Real Time Software (General)" [B.16-20].	Compliant

N290.14-15 Clause	PSR2 Review	Compliant or Gap
	As part of work assignment, the supervision ensures the personnel are qualified to perform the assigned task. Specific applicable qualifications are [B.16-20], [B.16-21]: • Qual ID 16934, Software Categorization Specialist • Qual ID 7771, DE- Safety Critical Software Engineering • Qual ID 7772, DE-Real Time Computer Systems (Hardware) • Qual ID 6286, DE-Real Time Software In addition to these qualification IDs, required core qualifications include [B.16-19], [B.16-20]: • Qual ID 6168 Engineering Support Personnel - Core Training • Qual ID 33685 Design Engineer N-INS-69000-10002, "Computer Spare Parts and Other Electronic Components Acquisition by Computers and Control Design Department" [B.16-22], Section 4.1 identifies the specific qualifications required for computer related acquisitions (included in the above). b) The applicable standards are identified in the relevant STIs and N-PROC-MP-0099, "Development of Real-Time Process Computing Systems" [B.16-17]. c) This is outlined in Section 3, 4, & 5 of the STI, N-STI-69000-10000-R004, "Software Categorization" [B.16-18], where the standard requires the user to understand the purpose and significance of the application being evaluated. Sections 4.3.1 and 4.3.2 of N-PROC-MP-0099 [B.16-17], provide a detailed list of Performance and Developmental references.	
6 Qualification activities	Heading only	N/A

N290.14-15 Clause	PSR2 Review	Compliant or Gap
6.1 Identifying and classifying digital items	Clarification only. Section 6.1 is a new addition to the 2015 version of the standard that did not explicitly exist in the R2012 version of the standard.	N/A
6.1.1 Comprehensive list A comprehensive list of all digital items within the candidate product shall be compiled. **Note:** *Annex C provides some examples of identification of digital items found in a candidate product.* Annex C is not mandatory. It identifies six general categories: 1) General 2) Smart Transmitter 3) PLC Controller 4) PC-based solution 5) Distributed control System 6) Custom FPGA-based device And, provides advice with respect to the listing.	Depending on the type of application and its Categorization, the level of detail required differs, per N-PROC-MP-0099, "Development of Real-Time Process Computing Systems" [B.16-17], Sections 1.3 and 1.4, (also including custom applications) which specify the standards and requirements that are applicable. For example, N-STI-69000-10003, "Category II / III Software Design" [B.16-24], Section 4.2.3.3 details the types of modules that should be identified. For the software, N-FORM-10409, "Software Quality Assurance Requirements" [B.16-23] identifies the quality assurance requirements for Category I/II/III software, which is in accordance with N290.14, consistent with the 2015 version of the standard. Hence, the 2015 code requirements are met.	Compliant
6.1.2 Identifying item types Each digital item listed in accordance with Clause 6.1.1 shall be identified as one of the following: a) pre-developed software; b) custom software; c) digital hardware; or d) software engineering tool.	The R2012 version of the standard was only applicable to pre-developed software. The 2015 version has expanded the scope to the four identified applications. Item d) *software engineering tool*, has been introduced. This refers to tools used in software testing and development and differs from Scientific, Engineering, and Safety Analysis (SESA) software. The procedures and guidance detailed in clause 6.1.1 address all these aspects.	Compliant
6.1.3 Minor customizations	Heading only	N/A
6.1.3.1 Software with minor customizations may be considered to be pre-developed software digital items.	This is recognized in OPG procedures N-PROC-MP-0049, "Procurement of Software and Products Containing Software" [B.16-14], as Modifiable Off-The Shelf (MOTS).	Compliant

N290.14-15 Clause	PSR2 Review	Compliant or Gap
6.1.3.2 Where a pre-developed software digital item is modified with minor customizations, complementary testing shall be performed on the customizations in order to verify that they do not invalidate any qualification-related conclusions. Failures uncovered during the testing shall be subject to impact analysis, corrective action, and retesting. **Note:** *The scope of testing should be justified based on the impact that the modifications have on the candidate product's ability to meet its functional and safety requirements.*	This is identified in N-FORM-10408, "Software Procurement Planning" [B.16-25], where the Section F selection directs to the mandatory software qualification requirements as listed in Appendix B of N-PROC-MP-0049, "Procurement of Software and Products Containing Software" [B.16-14]. The MOTS software are directed to the Custom (CUST-I/II/III/IV) software quality assurance requirements.	Compliant
6.2 Qualification concerns The candidate product shall be assessed against the concerns identified in Annex A. Annex A is mandatory and includes addressing the following: A.1 General A.2 Silent or undetected failure A.3 Flooding, determinism, and performance A.4 Common mode A.5 Security A.6 Power interruption or restart A.7 Time Dependant behaviour A.8 Modal behaviour A.9 Shared resources A.10 Upgrades A.11 Maintainability issues A.12 Extra functionality A.13 Communications A.14 Coexistence A.15 User interface A.16 Other postulated failure modes	N-PROC-MP-0049, "Procurement of Software and Products Containing Software" [B.16-14], Appendix B identifies that the supplier must qualify software in accordance with N290.14 for Commercial off the Shelf (COTS-I/II/III) and Custom (CUST-I/II/III) software. This list of qualification concerns is essentially the same in the 2012 and 2015 versions of N290.14. However, the requirement to qualify for A.14 'Coexistence' relating to wireless technology has been introduced in the 2015 version. N-PROC-MP-0103, "Security for Real-Time Process Computing Systems" [B.16-26], Section 1.3 applies restrictions on the use of wireless technology and requires a Wireless Technology Risk Assessment to document how potential hazards are mitigated when wireless technology is used. In addition, N-STI-69000-10013, "Computer System Requirements and Design" [B.16-11], requires environmental requirements to be specified (e.g., electromagnetic interference or radio frequency interference). Guidance on transient immunity testing is provided in N-DG-60407-10000, "Guidelines for Electromagnetic Compatibility Test" [B.16-27]. Additionally, A.13 related to 'communications' has been expanded to identify that communication must be c) robust under credible environment and d)	Compliant

N290.14-15 Clause	PSR2 Review	Compliant or Gap
	compliant with a recognized and appropriate standard for digital communication. For c), N-STI-69000-10013, "Computer System Requirements and Design" [B.16-11], requires that the environmental conditions for qualification be established. N-PROC-MP-0049, "Procurement of Software and Products Containing Software" [B.16-14], Section 1.6.1 ensures supplier tests for target installation. For d) digital communication protocol would be identified in the specification for procurement as a standard practice. Hence, neither of the changes relating to A.13 'communication' are gaps.	
6.3 Failure analysis requirements	Heading only	Compliant
6.3.1 For Category 1 applications, failure modes shall be identified and analyzed for the candidate product, using a rigorous technique (e.g., FMEA, fault tree analysis (FTA), Hazard and operability analysis (HAZOP), Systems theoretic process analysis (STPA), etc.). **Note:** *For guidance on failure analysis techniques recognized standards such as the following may be used:* a) *IEC 62502 for event tree analysis;* b) *IEC 60812 for failure mode and effects analysis;* c) *IEC 61882 for hazard and operability studies;* d) *IEC 61025 for fault tree analysis; and* e) *EPRI 3002000509 for hazard analysis.*	There are currently no Category I applications in use at Pickering. However, this requirement is reflected in N-STI-69000-10013, "Computer System Requirements and Design" [B.16-11], Section 5.3.23, 6.3.4.1(f) and CE-1001-STD, "CANDU Computer Systems Engineering Centre of Excellence Standard for Software Engineering of Safety Critical Software" [B.16-28], Section 4.4.1. Failure analysis requirements are cited in the 2012 version of the standard referenced in OPG governance (e.g., N-PROC-MP-0049, "Procurement of Software and Products Containing Software" [B.16-14], Appendix B). The 2015 version has only introduced the assessment techniques and references.	N/A
6.3.2 For candidate products that are determined to perform Category 1 functions, or where candidate product complexity warrants, more than one complementary technique should be used.	See 6.3.1	N/A

N290.14-15 Clause	PSR2 Review	Compliant or Gap
6.3.3 For Category 2 and 3 applications, failure modes should be identified and analyzed for the candidate product, using a rigorous technique (e.g., FMEA, FTA, HAZOP, STPA, etc.).	See 6.3.1	Compliant
6.4 Digital item qualification activities	Heading only	N/A
6.4.1 Pre-developed software	The qualification approaches for pre-developed and custom software are specified per either procedure N-PROC-MP-0049, "Procurement of Software and Products Containing Software" [B.16-14] or N-PROC-MP-0099, "Development of Real-time Process Computing Systems" [B.16-17]. These procedures and associated forms specify the qualification approaches for the two types of software under the applicable Standards. Note, the 2007 version of the standard and its application is referenced as required in OPG governance.	Compliant
6.4.1.1 General Each pre-developed software item shall be assessed using one of the methods for qualification specified in Clause 6.4.1.2 to ensure reliable performance of the software's safety-related functions. **Notes:** **1)** *It is intended that the assessment specified in this Clause will help ensure that the software does not contain bugs or flaws that could impair the software's ability to perform its function in the intended application or to handle predictable hardware and system interface errors.* **2)** *Table 2 provides guidance for selecting a method for qualification based on the category of the application.*	See 6.4.1	Compliant
6.4.1.2 Methods for qualification	Heading only	N/A
6.4.1.2.1 Recognized program	See 6.4.1	Compliant

N290.14-15 Clause	PSR2 Review	Compliant or Gap
6.4.1.2.2 Mature product method	See 6.4.1	Compliant
6.4.1.2.3 Proof through testing The proof through testing method may be applied to pre-developed software digital items, and that are to be used in Category 3 applications. This method may be used when either Item a) or b) below is true: …	See 6.4.1. This clause is a new addition to the 2015 version of the standard. It is intended to provide more flexibility for pre-developed software and does not impose more stringent requirements.	Compliant
6.4.1.2.4 Preponderance of evidence The preponderance of evidence method may be applied to pre-developed software digital items to be used in Category 1, 2, or 3 applications. This method shall consist of one or more of the following elements. The following elements shall be considered for this method:…	See 6.4.1	Compliant
6.4.2 Custom software	Heading only	N/A
6.4.2.1 General Custom software shall be developed in accordance with an appropriate standard or guideline as listed in Table 3.	See 6.4.1	Compliant
6.4.2.2 Documentation All documents required by the appropriate standard or guideline shall be available so that conformance can be confirmed.	See 6.4.1	Compliant
6.4.3 Digital hardware	As identified in Clause 1.1 above, Digital Hardware is a new addition to the standard which is addressed via OPG programs and design standards.	Compliant
6.4.3.1 General Hardware requirements shall be specified consistent with CSA N290.8. **Notes:** **1)** *For the purpose of qualifying digital hardware, the relationship of this Standard to CSA N290.8 is that the requirements for the digital hardware are specified in accordance with CSA N290.8, and this Standard identifies assessments to be conducted to verify compliance with the stated requirements.* **2)** *For the purpose of supplying digital hardware this Standard assumes that the supplier is qualified to supply the scope of*	Note, N290.8 is generic and applicable to developing specifications for any nuclear component. It is not specific to digital hardware. N-PROC-MP-0090, "Modification Process" [B.16-15] is applicable to digital hardware design and changes. If a digital component contains software N-PROC-MP-0049, "Procurement of Software and Products Containing Software" [B.16-14], is initiated. N-INS-69000-10002, "Computer Spare Parts and Other Electronic Components	Compliant

N290.14-15 Clause	PSR2 Review	Compliant or Gap
work consistent with the requirements in CSA N286.	Acquisition By Computers and Control Design Department" [B.16-22], details the managed process for procuring hardware and interfaces with N-PROC-MP-0098, "Procurement Engineering Activities" [B.16-29], which ensures that the Quality Control and Quality Assurance requirements for hardware are adhered to. Hardware is specified in accordance with N-STI-69000-10013, "Computer System Requirements and Design" [B.16-11].	
6.4.3.2 Hardware assessment	Heading only	N/A
6.4.3.2.1 Environmental tolerance assessment An environmental tolerance assessment shall be conducted against the requirements specified in the technical specification…	This is addressed in the specification developed in accordance with, N-STI-69000-10013, "Computer System Requirements and Design" [B.16-11], Section 5.3.13.	Compliant
6.4.3.2.2 Electromagnetic immunity and emissions assessment An electromagnetic immunity and emissions assessment shall be conducted against the requirements specified in the technical specification…	See 6.4.3.2.1	Compliant
6.4.3.2.3 Seismic tolerance assessment A seismic tolerance assessment shall be conducted against the requirements specified in the technical specification…	See 6.4.3.2.1	Compliant
6.4.3.3 Hardware engineering process assessment	Heading only	N/A
6.4.3.3.1 Hardware testing techniques assessment A hardware testing techniques assessment shall be conducted...	These activities are conducted by Procurement Engineering, N-PROC-MP-0098, "Procurement Engineering Activities" [B.16-29], combined with vendor surveillance. The Computer Engineering department establishes the requirements and design and is involved with the acceptance of test/qualification results. There are several procurement specifications e.g., N-TSI-60XXX and standards N-STI-60XXX, relating to I&C and digital hardware components, e.g., N-STI-60407-10003, "Specification for OPG	Compliant

N290.14-15 Clause	PSR2 Review	Compliant or Gap
	Radiated Susceptibility Field Test" [B.16-30]. N-TSI-60458-10000, "Digital Process Controllers" [B.16-31], Section 1.2 provides an example of applicable standards and specifications. Additionally, this specification provides manufacturer accountabilities.	
6.4.3.3.2 Hardware design process assessment A hardware design process assessment shall be conducted. The following shall be considered: a) use of automated design tools; b) change control and configuration management of the design; and c) design practices to improve reliability, robustness, and fault tolerance…	See 6.4.3.3.1	Compliant
6.4.3.3.3 Product manufacturing process methods assessment A manufacturing process methods assessment shall be conducted.	See 6.4.3.3.1	Compliant
6.4.3.4 Third party certification assessment All third party certifications shall be assessed to determine if they can be used in part or entirely to satisfy the assessments identified in Clause 6.4.3…	There are no specific requirements relating to third party certification identified for hardware. However, providing evidence of third party testing (i.e., certification) is done as part of the standard I&C procurement. Also, third party certification for software is explicitly addressed in N-PROC-MP-0049, "Procurement of Software and Products Containing Software" [B.16-14].	Compliant
6.4.4 Software engineering tool Software engineering tools used for the configuration, maintenance of digital items, or the development of custom software shall be qualified in accordance with Annex D.	This is a new requirement introduced in the 2015 version of the Standard. Annex D is Mandatory. This requirement is addressed in Section 1.1 of N-PROG-MP-0006, "Software" [B.16-8], *"(c) Except as above, for software that meets the definition of Software Engineering Tool, the classification of the target application (i.e., RTPC or SESA*	Compliant

N290.14-15 Clause	PSR2 Review	Compliant or Gap
	software) is used to determine the applicable standards and procedures." Hence, because the 'tool' is qualified to the same extent as the application, the new requirement does not impose any additional requirements.	
6.5 Qualification results	Heading only	N/A
6.5.1 The qualification of a candidate product shall be documented in a qualification report. **Note:** *The qualification report may consist of one or more documents.* **6.5.2** The identification of all digital items within the candidate product undergoing qualification and the context of how the candidate product fits into the overall system of which it is a component shall be clearly identified. **6.5.3** The qualification report shall document the failure analysis assessment when required along with the mitigation strategies for the deficiencies identified during the assessment. **6.5.4** The qualification report shall identify the safety category or categories of the safety-related functions to be performed by the candidate product. **6.5.5** The qualification report shall identify the candidate product, including the versions of all software and hardware within the candidate product. Where software is used, the target platform and key aspects of the configuration shall be specified (see Clause 6.5.13b)). **6.5.6** The qualification report shall provide the rationale and supporting evidence used to justify the individual categorization of functions of individual components of the candidate product (see Clause 5.2.3). **6.5.7** The qualification report shall have an assessment of each of the qualification	The "Qualifications Results" section of the standard has been extensively revised from the R2012 to the 2015 version of N290.14. N-FORM-10409, "Software Quality Assurance Requirements" [B.16-23] and N-PROC-MP-0049 [B.16-14], "Procurement of Software and Products Containing Software", specify that CSA N290.14 must be complied with. Although the section is revised, for the most part the individual clauses have just been modified or moved to improve clarity. However, Clause 6.5.13 identifies new requirements for software and hardware combined in a candidate product. As discussed in Clause 1.1 above, there are applicable OPG standards, including N-STI-69000-10013, "Computer System Requirements and Design" [B.16-11], which outlines requirements for software and hardware design (e.g., design constraints and margins) and N-STI-69000-10005, "Category II/III Software Testing" [B.16-12], which identifies requirements for integration testing.	Compliant

N290.14-15 Clause	PSR2 Review	Compliant or Gap
concerns listed in Clause 6.2, including all relevant arguments and qualification evidence.		
6.5.8 The qualification report shall document the qualification results of each digital item identified in Clause 6.1. **6.5.9** The qualification result for each identified digital item shall conclude one of the following: a) The digital item in the candidate product is qualified for the intended use, subject to the limits identified by Clause 6.5.13. b) The digital item in the candidate product is not qualified for the intended use. c) The digital item in the candidate product is conditionally qualified for the intended use once identified activities (e.g., further analysis or testing) are successfully completed, and subject to the limits identified by Clause 6.5.13. **6.5.10** The qualification report shall document and summarize the overall qualification conclusion of the candidate product based on the results of the digital item(s) being evaluated. **6.5.11** The qualification report shall document personnel qualification for the individuals who have been party to the assessment of the candidate product and completion of the qualification report. **6.5.12** The report shall identify the qualification method for the digital items within the candidate product as per Clause 6.4.1.2. **6.5.13** When the software and hardware in the candidate product is qualified for the identified use, limits shall be identified and documented to specify the candidate product operating envelope within which it is acceptable to use the candidate product. Limits can include identification of a) limits of the candidate product's functionality; b) limits of the intended safety-related functions of the product; c) assumptions about the system in which the candidate product is to be used;		

N290.14-15 Clause	PSR2 Review	Compliant or Gap
d) limits of the platform and operating conditions; e) configuration parameters and the limits imposed on their values; f) interface constraints; g) user-configured safety-related functions and their appropriate documentation; h) performance and security limits; and i) life-time limiting components… **6.5.14** When a candidate product has minor customizations, the qualification report shall document the nature of the customizations, and the results of any complementary testing and the impact on the qualification conclusions.		
7 Maintaining qualification All software and hardware changes shall be documented and evaluated to determine the effect on the existing qualification. If such changes cannot be demonstrated to have no significant effect on the existing qualification, re-qualification of the component to the original criteria shall be conducted…	Per N-PROC-MP-0100, "Maintenance of Real-Time Process Computing Systems" [B.16-32], a change control procedure that is in conformance with ECC is to be defined for each computer-based system containing software. Requirements are identified in N-STI-69000-10001, "Software Maintenance" [B.16-33]. Section 3.3.5 specifies the configuration management requirements. Section 3.4 details the requirements for a Software Maintenance Plan (SMP). Section 3.0 refers to N-STI-69000-10019, "Configurable Software for Real-Time Process Computing Systems" [B.16-34], for the interpretation of the requirements within the standards and issues when using configurable software.	Compliant

B.16.3 Compliance Summary for Pickering PSR2

There is one PSR2 CSA N290.14-15 gap relating to Safety Factor 1 (Plant Design):

1. Correspondence with the CNSC [B.16-7] identifies all of the software application qualifications for software Categories 1, 2 and 3 from January 1, 2007 to the time of the correspondence (June 2016). However, an evaluation of legacy Real-Time Process Computing applications with respect to the requirements of N290.14-15 for Categories 1, 2 and 3 software has not been performed. Therefore, this has been identified as a PSR2 gap.

B.17 CSA N291-15, "Requirements for Safety-Related Structures for Nuclear Power Plants"

B.17.1 Background

The following, paraphrased from the preface and scope of CSA N291-15 [B.17-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of CSA N291 is to specify the requirements for the material, analysis & design, construction, fabrication, inspection, examination and aging management of safety-related structures constructed of structural steel, reinforced concrete, and reinforced masonry. The minimum design requirements specified in this Standard follow the requirements of CSA A23.3, CSA S16, CSA S304.1, and the National Building Code of Canada.*
>
> *The standard provides a general definition of safety-related structures and ensures that the design and analysis of safety-related structures cover static and dynamic loads, and the loads, load factors, load combinations, and safety criteria cover service loads and abnormal/environmental loads.*

All of CSA N291-15 is directly relevant to Safety Factor 1 (Plant Design). CSA N291-15 includes clauses pertaining to in-service examinations (Clause 7) and aging management (Clause 9) that are also relevant to Safety Factor 2 (Actual Condition of SSCs) and Safety Factor 4 (Aging).

CSA N291 is identified in Appendix E.1 of the R04 Pickering Licence Conditions Handbook (LCH) [B.17-2] as "Guidance or Criteria". As indicated in Section 6.1 of the LCH, CSA N291 provides additional recommendations and guidance for development of the design program. As indicated in Section 7.1 of the LCH, CSA N291 provides additional recommendations and guidance for the development of inspection programs for balance of plant.

CSA N291-15 is the second edition of this standard, and supersedes the previous edition published in 2008 under the title "Requirements for Safety-Related Structures for CANDU Nuclear Power Plants" [B.17-3]. The noteworthy changes introduced as part of this revision are summarized in [B.17-4][15] and detailed in Section B.17.2.2 below.

Prior to the 2015 edition, Update No.1 to the 2008 edition was released in 2011 to incorporate a small number of minor clarifications [B.17-5]. Update No. 2 was issued in 2014 but only made an editorial change to a table column heading [B.17-6].

The results of PSR1 N291 reviews (Pickering A Return to Service assessments, and Pickering and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.17.2.1. As identified in Reference [B.17-7], the Pickering PSR2 review of CSA N291-15 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law,

---

[15] Note: The impact statement indicates a date of release of March 2016. However, the summary of changes have been compared to the second edition of CSA N291 (N291-15) and it is confirmed that this impact statement is meant to apply to this revision.

Regulation, Code or Standard (L/R/C/S) on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.
- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.17.2 Compliance Assessment for Pickering PSR2

B.17.2.1 Application of PSR1 Reviews

The versions of N291 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

The first edition of this standard was issued in March 2008 after the completion of the code reviews for the Pickering B ISR and Pickering A Return to Service. Therefore, no PSR1 code review was performed for Pickering NGS against CSA N291.

Darlington NGS

A clause-by-clause (non-PROL) intent review of N291-08 [B.17-3] was performed as part of the Darlington ISR, as documented in Reference [B.17-8]. Gaps were identified against fifteen clauses related to requirements for: anchorages, concrete coating inside containment structures, slenderness ratio of columns and tension members, embedded parts supporting piping or equipment designed for CSA N285 series and reinforcement detailing for joints, special detailing for other system components that interface with walls, walls and wall openings in concrete structures, and in-service examinations.

These gaps were grouped into six ISR Issues and documented in the Final ISR Report [B.17-9] as follows:

ISR Issue D071 - Coatings and Coverings Within Containment System

ISR Issue D283 - Design Requirements for Steel Safety-Related Structures

ISR Issue D284 - Load Factors for Metallic Embedded Parts in Safety-Related Building Structures

ISR Issue D285 - Seismic Design Provisions for Concrete Safety-Related Structures

ISR Issue D299 - Anchorage Requirements for Safety-Related Structures

ISR Issue D300 - Inspection Requirements for Safety-Related Structures.

With the exception of ISR Issue D300, all of the above were determined to have low safety significance and were dispositioned as Acceptable Deviations with No Further Action Required [B.17-9].

In addition, as summarized in Reference [B.17-10], two additional gaps against three clauses in CSA N291-08 were identified as part of the resolution of CNSC comments on the code review [B.17-8], as follows:

ISR Issue D401 - Load Factors for the Design of Nuclear Safety Related Structures

ISR Issue D411 - Approval of In-Service Examination Plans.

These issues were also determined to have low safety significance and were dispositioned as Acceptable Deviations with No Further Action Required, as documented in Reference [B.17-11]. The applicability to Pickering of the resolution of the Darlington ISR issues described above is discussed in Section B.17.2.2 below.

As described in the Final ISR Report [B.17-9], and reflected in the Darlington Global Assessment Report [B.17-12], D300 was identified as an ISR issue requiring action. This captured the finding that compliance with CSA N291-08 (specifically clauses 7.3.2.1, 7.3.2.2, 7.3.2.3, 7.3.3.1 and 7.3.3.2) could not be demonstrated due to no evidence being located to indicate that Darlington NGS had an active program for in-service examination that meets these requirements. In Reference [B.17-13], it was noted that subsequent to completion of the Darlington ISR code review against CSA N291-08, OPG had developed an aging management plan for non-containment structures. The recommended resolution per Reference [B.17-13] was as follows:

Initiate action(s) to establish a program for life-cycle management of safety-related structures in accordance with the requirements of N291-08.

By establishing an in-service examination program, OPG will ensure compliance with the requirements of CSA N291-08 and provide assurance that DNGS safety-related structures will continue to meet the design intent until the post-refurbishment end of plant life.

In Reference [B.17-10], OPG reported that in response to this issue, Periodic Inspection Program (PIP) plans had been developed for all safety-related structures at Darlington and that they will be implemented as part of the Integrated Aging Management Program [B.17-14], with schedules for inaugural inspections to be included in the Darlington ISR Integrated Implementation Plan (IIP), and that this response was accepted by the CNSC.

In the Darlington ISR IIP [B.17-15], ISR Issue D300 was assigned IIP Item number IIP-OI 038 with the following description:

There is a need to conduct regular in-service examinations of safety-related structures for evidence of degradation. The structures covered include:

-Those that support, house or protect nuclear safety systems,

-Components of structures required for the safe operation and reactor shutdown, and

-Facilities for storage of irradiated fuel and other radioactive waste material.

The Darlington ISR IIP [B.17-15] discussion of IIP-OI 038 listed the structures for which PIP plans had been prepared.

The applicability to Pickering of Darlington ISR gap D300 (IIP-OI 038) is discussed in Section B.17.2.2 below.

As part of the Darlington ISR, a code refresh review [B.17-16] was conducted against N291-08 (including Update No. 1) which found that the changes in the requirements are minor and reflect improvements for clarity or for formatting purposes. In conclusion, the review did not identify any additional gaps relative to the changes made in this update.

B.17.2.2 Application of Post PSR1 Reviews

In terms of applicability of the Darlington CSA N291-08 compliance assessment ([B.17-8] and [B.17-10]) and corresponding gap dispositions ([B.17-9] and [B.17-11]) to Pickering Units 1,4 and 5-8, it is noted that the Darlington conclusions are in general supported by making reference to Darlington-specific design documents. While the expectation is that similar conclusions would apply for Pickering, this cannot be confirmed without performing a more detailed review to identify the corresponding Pickering-specific design references.

A compliance review against CSA N291-08 [B.17-3] was not undertaken as a part of previous PSR1 reviews for Pickering NGS and the following incremental review has been performed against the Darlington CSA N291-08 compliance assessment. This incremental review includes high level review elements for portions of the Darlington compliance assessment that could not be readily applied to Pickering NGS due to station-specific differences. In the review below, the degree of conformance with clauses or groups of clauses in the L/R/C/S is assessed for Pickering NGS by reference to supporting evidence stating whether the intent of the requirements stipulated in the L/R/C/S is met.

Where high level review was determined to be necessary, Compliances and Gaps were identified, where required, as defined below:

- Compliance: Compliance indicates that the intent of the safety requirement is met.
- Gap: A Gap indicates that the intent of the safety requirement is not met.

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
0 Preface	There are no requirements specified. The preface describes the purpose of CSA N291-08.	N/A
1 Scope	There are no requirements specified. This section sets the context for CSA N291-08.	N/A

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
2 Reference Publications	There are no requirements specified. This section describes the publications that CSA N291-08 refers to.	N/A
3 Definitions	There are no requirements specified. This section defines various words, phrases, or acronyms, used in CSA N291-08.	N/A
4 General Requirements This section of CSA N291-08 defines the basis for jurisdictional boundaries between safety-related structures and structural components/parts designed and fabricated in accordance with other Codes and Standards. In addition, this section establishes requirements for the owner/licensee to establish and maintain an overall quality assurance program and establish requirements for: a) Design; b) Performance; c) Quality Assurance; d) In-Service Monitoring, Surveillance, and Examination; and e) Decommissioning.	In the PSR1 assessment [B.17-8], Darlington was deemed to be compliant with requirements related to jurisdictional boundaries based on a listing of safety-related buildings and structures being provided in a Nuclear Safety Design Guide. The equivalent document for Pickering NGS is P-LIST-06937-00001, "Pickering A and B List of Safety Related Systems" [B.17-17]. In the PSR1 assessment [B.17-8], Darlington was deemed to be compliant with requirements for establishing a quality assurance program based on the original quality assurance manual for the Darlington site. The establishment of a quality assurance program is a programmatic requirement for OPG Nuclear, which is common to both Darlington and Pickering NGS. These requirements are established through N-CHAR-AS-0002 [B.17-18], "Nuclear Management System", which spans all aspects of the business.	Compliant
5 Materials, Construction, and Operating Exposure Conditions	There are no requirement specified. The corresponding content in the document is a section heading.	N/A
5.1 Structural Steel This section specifies the material and product Standards and specifications for structural steel and fasteners. In addition, this section specifies requirements for materials and products to be identified and marked in accordance with CSA Standard S16.	In the PSR1 assessment [B.17-8], design documentation containing references to applicable Standards for structural steel was used to demonstrate Darlington's compliance with this section of N291-08. Pickering safety-related structures were designed in accordance with applicable Standards and specifications at that time, which meets the intent of this section of N291-08. Due to Pickering 1,4 and Pickering 5-8 being designed and constructed at different times, different Standards were used to design the corresponding safety-related structures, as described below.	Compliant

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
	• Pickering 1,4 structures were designed in accordance with the National Building Code of Canada (NBCC) and associated material specifications [B.17-19]. Where applicable, structure-specific requirements were included in the corresponding Design Manual (References [B.17-21] to [B.17-37]). • CSA S16 is listed as one of the applicable standards for steel structures in the Pickering 5-8 Plant Level Topical Design Basis Document [B.17-20].	
5.2 Concrete and Grout This section specifies the following requirements for the use of concrete and grout materials: • Applicable Standards, including deterioration mechanisms. • Maximum concrete temperatures during normal operating or post-accident conditions. • Upper and lower limits for concrete placing temperatures and grout placing temperatures. • Maximum temperature differential allowed when placing fresh concrete against existing concrete in walls and suspended slabs. • Material requirements for concrete and grout, including cement, water, and aggregate.	In the PSR1 assessment [B.17-8], design documentation containing references to CSA A23.1, CSA A23.2, CSA A3000, and CSA A179 was used to demonstrate Darlington's compliance with this section of N291-08. Pickering safety-related structures were designed in accordance with applicable Standards and specifications at that time, which meet the intent of this section of N291-08. Due to Pickering 1,4 and Pickering 5-8 being designed and constructed at different times, different Standards were used to design the corresponding safety-related structures, as described below. • Pickering 1,4 structures were designed in accordance with the NBCC and associated material specifications [B.17-19]. Where applicable, structure-specific requirements were included in the corresponding Design Manual (References [B.17-21] to [B.17-37]). • CSA A23.1 is listed as one of the applicable Standards for concrete and grout in the Pickering 5-8 Plant Level Topical Design Basis Document [B.17-20].	Compliant

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
• Testing requirements for concrete and grout.		
5.3 Reinforcing Steel This section specifies the requirements for reinforced steel, including: • Tensile test requirements; • Bend test requirements; • Provision of certified mill test reports; and • Identification/marking requirements for welded splices.	In the PSR1 assessment [B.17-8], design documentation containing references to the CSA G30 series of Standards for reinforcing steel was used to demonstrate Darlington's compliance with this section of N291-08. Pickering safety-related structures were designed in accordance with applicable Standards and specifications at that time, which meet the intent of this section of N291-08. Due to Pickering 1,4 and Pickering 5-8 being designed and constructed at different times, different Standards were used to design the corresponding safety-related structures, as described below. • Pickering 1,4 structures were designed in accordance with the NBCC and associated material specifications [B.17-19]. Where applicable, structure-specific requirements were included in the corresponding Design Manual (References [B.17-21] to [B.17-37]). • CSA G30.3, CSA G30.5, and CSA G30.12 are listed as applicable Standards for reinforcing steel in the Pickering 5-8 Plant Level Topical Design Basis Document [B.17-20].	Compliant
5.4 Pre-Stressing Steel This section specifies the requirements for materials used in the pre-stressing reinforcing systems of concrete structures. Specific requirements identified in this clause include: • Responsibilities of the owner/licensee to establish material qualification testing and conformance test requirements and the respective acceptance criteria. • Provision of certified mill test reports.	In the PSR1 assessment [B.17-8], design documentation containing references to CSA A23.1 was used to demonstrate Darlington's compliance with this section of N291-08. Pickering safety-related structures were designed in accordance with the applicable Standards and specifications at that time, which meet the intent of this section of N291-08. Due to Pickering 1,4 and Pickering 5-8 being designed and constructed at different times, different Standards were used to design the corresponding safety-related structures, as described below. • Pickering 1,4 structures were designed in accordance with the NBCC and associated materials specifications [B.17-19]. Where applicable, structure-specific requirements were included in the corresponding Design Manual (References [B.17-21] to [B.17-37]). • CSA A23.1 is listed as one of the applicable Standards for concrete and grout in the	Compliant

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
	Pickering 5-8 Plant Level Topical Design Basis Document [B.17-20].	
5.5 Masonry This section specifies requirements for masonry materials used in safety-related structures.	In the PSR1 assessment [B.17-8], design documentation containing references to CSA Standard CAN3-A371-M84 was used to demonstrate Darlington's compliance with this section of N291-08. Pickering safety-related structures were designed in accordance with the applicable Standards and specifications at that time, which meet the intent of this section of N291-08. Due to Pickering 1,4 and Pickering 5-8 being designed and constructed at different times, different Standards were used to design the corresponding safety-related structures, as described below. • Pickering 1,4 structures were designed in accordance with the NBCC and associated material specifications [B.17-19]. Where applicable, structure-specific requirements were included in the corresponding Design Manual (References [B.17-21] to [B.17-37]). • CSA A371 is listed as one of the applicable Standards for the design and construction of masonry structures in the Pickering 5-8 Plant Level Topical Design Basis Document [B.17-20].	Compliant
5.6 Stainless Steel This section specifies requirements for stainless steel used in safety-related structures. This includes: • Requirements for use of electrodes; and • Requirements for welding procedures.	In the PSR1 assessment [B.17-8], technical specifications containing references to applicable Standards for the use of stainless steel were used to demonstrate Darlington's compliance with this section of N291-08. Pickering safety-related structures were designed in accordance with the applicable Standards and specifications at that time, which meet the intent of N291-08. • Pickering 1,4 structures were designed in accordance with the NBCC and associated material specifications [B.17-19]. Where applicable, structure-specific requirements were included in the corresponding Design Manual (References [B.17-21] to [B.17-37]). • The NBCC and CSA W47.1 are listed as applicable Standards for the use of stainless steel in the Pickering 5-8 Plant Level Topical Design Basis Document [B.17-20].	Compliant

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
5.7 Anchorage *Anchorage shall meet the requirements of N287.2.*	There are no new requirements specified in this clause. N287.2 requirements are being assessed separately under PSR2, which includes consideration of the applicability of previous gaps identified in the PSR1 assessment for Darlington [B.17-8].	N/A
5.8 Other Materials *Materials other than those specified in this Standard may be used, provided that material tests are conducted to the satisfaction of the engineer.*	The PSR1 assessment for Darlington [B.17-8] concluded that this clause represents a general requirement where it is not necessary to assess compliance. This is a programmatic conclusion that also applies to Pickering.	N/A
5.9 Coatings This clause specifies requirements for: • Application of coatings to steel inside and outside containment structures; and • Application of coatings to concrete inside and outside containment structures.	In the PSR1 assessment [B.17-8], references to design documentation were used to demonstrate Darlington's compliance with this section of N291-08. Requirements specific to this section fall into two categories: • Application of coatings to structures inside containment shall be in accordance with CSA N287.2. • Application of coatings to structures outside of containment shall be in accordance with CSA S16. N287.2 requirements are being assessed separately as a part of PSR2, which includes consideration of the applicability of previous gaps identified in the PSR1 assessment for Darlington [B.17-8]. Thus, the scope of this assessment is limited to the requirements of CSA S16. Pickering safety-related structures were designed in accordance with the applicable Standards and specifications at that time, which meet the intent of N291-08. Due to Pickering 1,4 and Pickering 5-8 being designed and constructed at different times, different Standards were used to design the corresponding safety-related structures, as described below. • Pickering 1,4 structures were designed in accordance with the NBCC and associated material specifications [B.17-19]. Where applicable, structure-specific requirements were included in the corresponding Design Manual (References [B.17-21] to [B.17-37]). • CSA S16 is listed as one of the applicable Standards in the Pickering 5-8 Plant Level Topical Design Basis Document [B.17-20].	Compliant

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
6 Analysis and Design	There are no requirements specified. The corresponding content in the document is a section heading.	N/A
6.1 General This section identifies applicable Standards for the design and analysis of safety-related structures. In addition, for structures subjected to complex dynamic loads such as drop and impact loads, test and/or analysis may be used.	In the PSR1 assessment [B.17-8], references to design documentation were used to demonstrate Darlington's compliance with this section of N291-08. Pickering safety-related structures were designed and analyzed in accordance with the applicable Standards and specifications at that time, which meet the intent of this section of N291-08. Due to Pickering 1,4 and Pickering 5-8 being designed and constructed at different times, different Standards were used to design the corresponding safety-related structures, as described below. • Pickering 1,4 structures were designed and analyzed in accordance with the NBCC [B.17-19]. Structure-specific requirements regarding dynamic loads are provided in the corresponding Design Manuals (References [B.17-21] to [B.17-37]). • CSA S16 (structural steel), CSA A23.3 (concrete structures) and CSA A371 (masonry structures) are listed as applicable Standards in the Pickering 5-8 Plant Level Topical Design Basis Document [B.17-20]. Structure-specific requirements regarding dynamic loads are provided in the corresponding Design Manuals (References [B.17-38] to [B.17-55]).	Compliant
6.2 Symbols This clause defines symbols associated with loads, internal moments, and forces.	There are no requirements specified. The corresponding content in the document is a listing of symbols that does not impose any requirements on safety-related structures.	N/A
6.3 Load and Load Factors, Load Combinations, and Limit States This section identifies requirements related to loads considered in the design and analysis of safety-related structures. Specific requirements include: • Loads considered in the design.	In the PSR1 assessment [B.17-8], references to design documentation were used to demonstrate Darlington's compliance with this section of N291-08. As part of the PSR1 assessment [B.17-8], discrepancies were identified between load factors documented in station Design Manuals and prescribed load factors in this section of N291-08. ISR Issue D401 was created to determine the safety-significance of these discrepancies [B.17-11]. As noted in Section B.17.2.1 of this document, ISR Issue D401 was determined to have a low safety significance and was dispositioned as an acceptable deviation with no further action required.	Compliant

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
• Load combinations considered in the design. • Design of structures for sufficient strength and stability. • Design of structures to meet serviceability requirements.	Pickering safety-related structures were designed and analyzed in accordance with the applicable Standards at that time, which meet the intent of N291-08. Given that Pickering meets the intent of N291-08, it is appropriate to apply the assessment of the safety significance of ISR Issue D401 to Pickering. A new gap is not required for PSR2. Due to Pickering 1,4 and Pickering 5-8 being designed and constructed at different times, different Standards were used to design the corresponding safety-related structures, as described below. • Pickering 1,4 structures were designed and analyzed in accordance with the NBCC [B.17-19]. Structure-specific requirements for load factors and combinations were included in the corresponding Design Manuals (References [B.17-21] to [B.17-37]). • Pickering 5-8 structures were designed and analyzed in accordance with the Standards listed in Reference [B.17-20]. Structure-specific requirements for load factors and load combinations were included in the corresponding Design Manuals (References [B.17-38] to [B.17-55]).	
6.4 Seismic Design This section identifies requirements for the seismic analysis of safety-related structures, including: • Requirements for dynamic analysis; • Applicable Standards for seismic analysis; • Specification of live load reduction in computation of seismic forces; and • Requirements to avoid the interaction of elements to seismic motion.	In the PSR1 assessment [B.17-8], design documentation containing references to the NBCC and CSA CAN3-N289.3 was used to demonstrate Darlington's compliance with this section of N291-08. Pickering safety-related structures were designed and analyzed in accordance with the applicable Standards at that time, which meet the intent of N291-08. • Pickering 1,4 structures were initially designed and analyzed in accordance with the NBCC [B.17-19], with supplemental requirements included in the corresponding Design Manuals (References [B.17-21] to [B.17-37]). Subsequently, a seismic assessment of Pickering A was performed to confirm safe operation following a credible seismic event. Relevant documentation from this work includes References [B.17-56] to [B.17-58]. • Pickering 5-8 was designed to be seismically qualified, as described in Section 8.1 of the Pickering B Separation Philosophy & Common Mode Events Topical Design Basis Document [B.17-59]. Additionally, Section 8.2 of [B.17-59] includes references to the NBCC and N289 series of Standards. A complete listing of	Compliant

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
	structures with design basis requirements for seismic events is documented in Section 8.6.3 of [B.17-59].	
6.5 Foundations This section identifies requirements for the design and analysis of foundations, including: • Applicable Standards; • Requirement that safety-related structures shall not be built on strata that are potentially subject to liquefaction; and • Analysis of effects of fluctuating ground water in settlement analysis and evaluation of soil capacity.	In the PSR1 assessment [B.17-8], design documents containing references to the NBCC were used to demonstrate Darlington's compliance with this section of N291-08. Pickering safety-related structures were designed and analyzed in accordance with the applicable Standards at that time, which meet the intent of N291-08. • Pickering 1,4 structures were designed and analyzed in accordance with the NBCC [B.17-19]. • Pickering 5-8 structures were designed and analyzed in accordance with the NBCC [B.17-20]. In the PSR1 assessment, requirements related to liquefaction were determined to be not applicable as there was no evidence that any safety-related systems were built on strata potentially subject to liquefaction [B.17-8]. This conclusion also applies to Pickering NGS as the corresponding Design Manuals (References [B.17-21] to [B.17-55]) do not contain any evidence that safety-related structures were built on strata potentially subject to liquefaction.	Compliant
6.6 Steel Structures This section identifies requirements for the design of safety-related steel structures, including: • Applicable Standards; • Use of plastic analysis in the design process; • Requirements for bolted connections; • Slenderness ratios for structural steel members. • Requirement for fasteners to be installed with locking devices where connections are subjected to	In the PSR1 assessment [B.17-8], design documents containing references to CSA S16 were used to demonstrate Darlington's compliance with this section of N291-08. As part of the PSR1 assessment [B.17-8], discrepancies were identified between the slenderness ratios specified in this section of N291-08 and CSA S16. ISR Issue D283 was created to determine the safety-significance of these discrepancies [B.17-9]. As noted in Section B.17.2.1 of this document, ISR Issue D283 was determined to have a low safety significance and was dispositioned as an acceptable deviation with no further action required. Pickering safety-related structures were designed and analyzed in accordance with the applicable Standards at that time, which meet the intent of N291-08. Given that Pickering meets the intent of N291-08, it is appropriate to apply the assessment of the safety significance of Issue D283 to Pickering. A new gap is not required for PSR2. Due to Pickering 1,4 and Pickering 5-8 being designed and constructed at different times, different Standards were used to	Compliant

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
dynamic loads and/or vibration. • Specification of load factors for steel components supporting piping or equipment.	design the corresponding safety-related structures, as described below. • Pickering 1,4 structures were designed and analyzed in accordance with the NBCC [B.17-19]. General requirements from the NBCC were supplemented by structure-specific requirements contained in the corresponding Design Manuals (References [B.17-21] to [B.17-37]). • CSA S16 is listed as an applicable Standard for steel structures in the Pickering 5-8 Plant Level Topical Design Basis Document [B.17-20]. General requirements from S16 were supplemented by structure-specific requirements contained in the corresponding Design Manuals (References [B.17-38] to [B.17-55]).	
6.7 Concrete Structures This section identifies requirements for the design of safety-related concrete structures, including: • Applicable Standards; • Consideration of cracked section properties for thermally-induced loads; • Design requirements for metallic embedded parts for building structures; • Load factors for metallic embedded parts supporting piping or equipment. • Requirements for welded joints.	In the PSR1 assessment [B.17-8], design documentation containing references to CSA A23.3, CSA S16, and CSA W59 was used to demonstrate Darlington's compliance with this section of N291-08. As part of the PSR1 assessment [B.17-8], discrepancies were identified between the load factors documented in station Design Manuals and the prescribed load factors in this section of N291-08. Specifically, the discrepancies identified related to load factors for metallic embedded parts supporting piping or equipment designed in accordance with the CSA N285 series of Standards. ISR Issue D284 was created to determine the safety-significance of these discrepancies [B.17-9]. As noted in Section B.17.2.1 of this document, ISR Issue D284 was determined to have a low safety significance and was dispositioned as an acceptable deviation with no further action required. Pickering safety-related structures were designed and analyzed in accordance with the applicable Standards at that time, which meet the intent of N291-08. Given that Pickering meets the intent of N291-08, it is appropriate to apply the assessment of the safety significance of ISR Issue D284 to Pickering. A new gap is not required for PSR2. Due to Pickering 1,4 and Pickering 5-8 being designed and constructed at different times, different Standards were used to design the corresponding safety-related structures, as described below. • Pickering 1,4 structures were designed in accordance with the NBCC [B.17-19]. General	Compliant

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
	requirements from the NBCC were supplemented by structure-specific requirements documented in the corresponding Design Manuals (References [B.17-21] to [B.17-37]). • CSA A23.3, CSA S16.1, and CSA W59.1 are all listed as applicable Standards in the Pickering 5-8 Plant Level Topical Design Basis Document [B.17-20].	
6.8 Masonry Structures This section identifies requirements for the design of safety-related masonry structures, including high-density concrete block walls. Requirements identified in this clause include: • Applicable Standards; • Restrictions on the use of unreinforced masonry structural elements.	In the PSR1 assessment [B.17-8], design documentation containing references to CSA Standard CAN3-S304-M84 was used to demonstrate Darlington's compliance with this section of N291-08. Pickering safety-related structures were designed in accordance with the applicable Standards at that time, which meet the intent of N291-08. Due to Pickering 1,4 and Pickering 5-8 being designed and constructed at different times, different Standards were used to design the corresponding safety-related structures, as described below. • Pickering 1,4 structures were designed in accordance with the NBCC [B.17-19]. • CSA S304 is listed as an applicable Standard for masonry structures in the Pickering 5-8 Plant Level Topical Design Basis Document [B.17-20]. In the PSR1 review, requirements related to the use of unreinforced masonry structural elements were determined to be not applicable as there was no evidence that unreinforced masonry elements were used in any safety-related structures [B.17-8]. This conclusion also applies to Pickering NGS as the corresponding Design Manuals (References [B.17-21] to [B.17-55]) do not contain any evidence that unreinforced masonry elements were used in any safety-related structures.	Compliant
6.9 Displacement of Structures This section specifies limitations on the maximum displacements of structures or buildings.	In the PSR1 assessment [B.17-8], design documents containing references to the NBCC were used to demonstrate Darlington's compliance with this section of N291-08. Pickering safety-related structures were designed in accordance with the applicable Standards at that time, which meet the intent of N291-08. • Pickering 1,4 structures were designed and analyzed in accordance with the NBCC [B.17-19].	Compliant

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
	• Pickering 5-8 structures were designed and analyzed in accordance with the NBCC [B.17-20].	
6.10 Concrete Structures with Non-Metallic or Metallic Liners This section identifies design requirements for metallic and non-metallic liners in safety-related concrete structures. • Applicable Standards; • Restrictions on use of rigid non-metallic liners as a primary leakage barrier. • Requirements to maintain uniform stress levels across the liner plate. • Requirements for water treatments and purification • Requirements for pool-type irradiated fuel storage bays.	In the PSR1 assessment [B.17-8], Design Manuals for the Irradiated Fuel Bay (IFB) were used to demonstrate Darlington's compliance with this section of N291-08. Equivalent documentation exists for the Pickering IFBs, which meets the intent of N291-08. The corresponding Design Manuals for Pickering 1,4 are References [B.17-28], [B.17-60], and [B.17-61]. The corresponding Design Manuals for Pickering 5-8 are References [B.17-46] and [B.17-62].	Compliant
7 Construction Inspection and In-Service Examination	There are no requirements specified. The corresponding content in the document is a section heading.	N/A
7.1 General This section identifies programmatic requirements related to construction inspections and in-service examinations, which include: • Responsibility of the engineer to establish a construction inspection and in-service examination program for all	Requirements for in-service examinations are assessed under Section 7.3. The assessment of Section 7.1 is limited to construction inspection programs. Pickering structures were initially constructed, inspected, and tested in accordance with the quality assurance program in effect at the time, which meets the intent of N291-08. Pickering 1,4 safety-related structures were designed, fabricated, constructed, inspected, and tested in accordance with Parts 4 through 8 of the NBCC [B.17-19]. General requirements from the NBCC were supplemented by structure-specific requirements documented in the corresponding Design Manuals (References [B.17-21] to [B.17-37]).	Compliant

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
safety-related structures. • Responsibility of the designer to identify critical components of structures requiring additional construction examinations and/or in-service examinations. • Specification of qualification requirements for personnel performing construction inspections and in-service examinations.	Pickering 5-8 safety-related structures were designed, fabricated, constructed, inspected, and tested in accordance with Parts 4 through 8 of the NBCC [B.17-65]. General requirements from the NBCC were supplemented by structure-specific requirements contained in the corresponding Design Manuals (References [B.17-38] to [B.17-55]).	
7.2 Construction Inspection This section identifies inspection and testing requirements applicable to the construction, installation, and fabrication of parts and components of safety-related structures. Applicable structures and components include: • Steel structures; • Welded joints; • Bolted joints; • Concrete and grout materials; • Reinforcing materials; • Arc-welded and mechanical splices; • Embedded parts; • Anchors; • Steel liners;	Requirements for in-service examinations are assessed under Section 7.3. The assessment of Section 7.2 is limited to construction inspection programs. Pickering structures were initially constructed, inspected, and tested in accordance with the quality assurance program in effect at the time, which meets the intent of N291-08. Pickering 1,4 safety-related structures were designed, fabricated, constructed, inspected, and tested in accordance with Parts 4 through 8 of the NBCC [B.17-19]. General requirements from the NBCC were supplemented by structure-specific requirements documented in the corresponding Design Manuals (References [B.17-21] to [B.17-37]). Pickering 5-8 safety-related structures were designed, fabricated, constructed, inspected, and tested in accordance with Parts 4 through 8 of the NBCC [B.17-65]. General requirements from the NBCC were supplemented by structure-specific requirements contained in the corresponding Design Manuals (References [B.17-38] to [B.17-55]).	Compliant

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
• Reinforced masonry structures.		
7.3 In-Service Examination This section specifies requirements for in-service examinations of safety-related structures and their components during the life of the plant. Key aspects of the in-service examination program include: • Definition of activities that comprise the program; • Considerations for the extent of examination and basis of comparison; • Examination frequency for safety-related structures; • Inspections of all structural components for safety-related structures following any abnormal/environmental conditions.	In the PSR1 assessment [B.17-8], design documentation containing references to CSA N287.7 was used to demonstrate Darlington's compliance with this section of N291-08. Additionally, references to operating documentation that would be used in response to a seismic event were used to demonstrate Darlington's compliance with requirements for inspections of structural components following abnormal plant conditions. There are separate activities being performed as a part of PSR2 to assess N287.7 requirements. Thus, assessment of this code is not discussed further in the context of N291-08. Pickering Containment structures (Reactor Building, Pressure Relief Duct, Vacuum Building) have full rigorous in-service inspection programs. As part of the PSR1 assessment [B.17-8], it was identified there was no evidence of an in-service examination program for safety-related structures outside of containment. These structures are not covered by N287.7 but are included in the scope of N291-08. ISR Issue D300 identified the need to address incomplete in-service examination plans for these structures. As noted in Section B.17.2.1 herein, Issue D300 was determined to require resolution. As discussed separately in the text immediately following this summary table, assessment of the applicability of ISR Issue D300 to Pickering operation beyond 2020 has been identified as a gap. This issue is identified as a PSR2 gap in OPG Report P-REP-03680-00024 R000, "Pickering 5-8 Continued Operations Plan Review in Support of PNGS Periodic Safety Review 2 (PSR2)" [B.17-69]. A duplicate gap under CSA N291-15 will not be created. For requirements specific to the inspection of structural components following abnormal plant conditions, the rationale provided for Darlington's response to a seismic event, through the use of Seismic Abnormal Incident Manuals (AIMs), also applies to Pickering NGS. The corresponding procedures for Pickering are References [B.17-63] and [B.17-64].	Gap **COP Gap relating to COP Action #31 [B.17-69]**
8 Seismic and Dynamic Considerations	There are no requirements specified. The corresponding content in the document is a section heading.	N/A

<table>
<tr><th>CSA N291-08 Clause</th><th>PSR2 Review</th><th>Compliant or Gap</th></tr>
<tr><td>8.1 General
This section specifies general requirements related to the consideration of seismic and dynamic loads in the design of safety-related structures.
Structures subject to seismic ground motion shall be designed elastically.
Identification of applicable Standards.
Restrictions on use of plain concrete in safety-related structures for structural purposes.</td><td>In the PSR1 assessment [B.17-8], design documentation containing references to CSA N289.2, CSA A23.3, and CSA S16 was used to demonstrate Darlington's compliance with this clause.
N289.2 requirements are being assessed under a separate code review that is being performed in support of PSR2. The scope of the assessment for this section of N291-08 is limited to CSA A23.3 and CSA S16.
Pickering safety-related structures were designed and analyzed in accordance with the applicable Standards at that time, which meet the intent of this section of N291-08. Due to Pickering 1,4 and Pickering 5-8 being designed and constructed at different times, different Standards were used to design the corresponding safety-related structures, as described below.
Pickering 1,4 structures were initially designed and analyzed in accordance with the NBCC [B.17-19], with supplemental requirements included in the corresponding Design Manuals (References [B.17-21] to [B.17-37]). Subsequently, a seismic assessment of Pickering A was performed to confirm safe operation following a credible seismic event. Relevant documentation from this work includes References [B.17-56] to [B.17-58].
CSA A23.3 and CSA S16 are both listed as applicable Standards in the Pickering 5-8 Plant Level Topical Design Basis Document [B.17-20].</td><td>Compliant</td></tr>
<tr><td>8.2 Analysis
Seismic and design analysis shall be performed in accordance with Clause 6.4.</td><td>There are no new requirements specified in this clause. The content of Section 8.2 is limited to a cross-reference to Section 6.4.</td><td>N/A</td></tr>
<tr><td>8.3 Design Provisions for Concrete Structures
This section specifies requirements for the seismic design and reinforcement detailing of concrete structural members, including the identification of applicable Standards.
These requirements apply to:</td><td>In the PSR1 assessment [B.17-8], design documentation containing references to CSA A23.3 was used to demonstrate Darlington's compliance with this section of N291-08.
As part of the PSR1 assessment [B.17-8], it was identified that N291-08 imposed more stringent requirements than what was imposed by the Standards in effect at the time Darlington was designed and constructed. These requirements were specifically for concrete safety-related structures outside of containment. ISR Issue D285 was created to determine the safety significance of the more stringent requirements imposed by N291-08 [B.17-9]. As noted</td><td>Compliant</td></tr>
</table>

CSA N291-08 Clause	PSR2 Review	Compliant or Gap
• Beams; • Columns; • Walls; • Openings; and • Joints.	in Section B.17.2.1 of this document, ISR Issue D285 was determined to have a low safety significance and was dispositioned as an acceptable deviation with no further action required. The assessment of Issue D285 was based on the existence of alternative methods used to demonstrate adequate assurance of Darlington's capability to withstand seismic events [B.17-9]. Similar work has been performed at Pickering NGS (References [B.17-56] to [B.17-59]) which demonstrates the station's capability to withstand a seismic event. Thus, it is appropriate to apply the assessment of the safety significance of ISR Issue D285 to Pickering. A new gap is not required for PSR2. Pickering safety-related structures were designed in accordance with the applicable Standards at that time, which meet the intent of this section of N291-08. Due to Pickering 1,4 and Pickering 5-8 being designed and constructed at different times, different Standards were used to design the corresponding safety-related structures, as described below. • Pickering 1,4 structures were designed in accordance with the NBCC [B.17-19]. Where applicable, structure-specific requirements are specified in the corresponding Design Manuals (References [B.17-21] to [B.17-37]). • CSA A23.3 is listed as an applicable Standard for the design of concrete structures in the Pickering 5-8 Plant Level Topical Design Basis Document [B.17-20].	
Annex A Special Provisions for Impulse and Impact Effects for Concrete Structures	Provides information and does not establish any requirements.	N/A
Annex B Waiting Periods for Placing Fresh Concrete Adjacent to Hardened Concrete	Provides information and does not establish any requirements.	N/A
Annex C Occupational Health and Safety Requirements for Access to Normally Inaccessible Structures	Provides information and does not establish any requirements.	N/A

Although the Pickering B ISR did not explicitly consider CSA N291-08, the Pickering Units 5-8 Continued Operations Plan (COP) [B.17-66] identified a completed action (Action #31 - F14-4.2 in Appendix A of [B.17-66]) that addresses CSA N291-08 in relation to the same issue associated with Darlington ISR Issue D300, discussed in Section B.17.2.1 above. Specifically:

> *Include the periodic inspection programs and LCMPs [Life Cycle Management Plans] for the safety-significant civil structures that are under the scope of CSA N291-08, but not covered by the N287.7 standard.*

Action #31 from the Pickering Units 5-8 COP [B.17-66] was closed in the context of Pickering operation up to 2020. This action involved submission of Periodic Inspection Plans and Life Cycle Management Plans for a number of safety-significant civil structures to address fitness for service "to end of mission time" (which will need to be extended for Pickering operation past 2020). The need to revisit Action #31 in the context of Pickering operation beyond 2020 relates specifically to CSA N291 and has been identified as a PSR2 gap in OPG Report P-REP-03680-00024 R000, "Pickering 5-8 Continued Operations Plan Review in Support of PNGS Periodic Safety Review 2 (PSR2)" [B.17-69]. This gap will consider both Pickering Units 1,4 and Pickering Units 5-8. A duplicate gap under CSA N291-15 will not be created.

Following the Darlington ISR, a code-over-code review [B.17-70] was conducted against N291-08 (including Updates No. 1 and No. 2). This review identified no significant technical changes to the requirements and, therefore, no impact on the findings of the reviews that had been performed previously.

The preceding discussion summarizes assessments that were performed in relation to CSA N291-08 (including Updates No. 1 and No. 2). For the purpose of PSR2, review against code edition CSA N291-15 is required. The CSA Impact Statement notification for N291-15 [B.17-3] identifies the following noteworthy changes from the previous edition (paraphrased):

1. *The word CANDU was removed from the title of the standard and technology neutral language was used.*
2. *The type of safety-related structure covered by this standard (Clause 1.1) was clarified.*
3. *Clarified the definition for safety-related structures, added new definitions and removed obsolete ones (Clause 3).*
4. *Sub-clauses under new Clause 5.2.3 clarify the requirements for "Concrete temperature at placing" and "Waiting Periods" and introduce new requirements for "Internal Concrete temperature for Mass Concrete".*
5. *Requirements for welding of reinforcing bars were added through new Clause 5.3.1.2 that refers to CSA W186.*
6. *The snow load requirement in Sub-clause 6.3.1(a)(iv) was updated to 100-year occurrence to be distinguished from the NBCC 2010, which uses 50-year occurrence.*
7. *The requirements on limiting strain conditions for safety-related structures were clarified:*

a. Sub-clause 6.3.3.3 was revised to provide clarification on the design of safety-related structures.

b. Annex A was revised to clarify the provisions for impulse and impact effects for concrete structures.

8. Seismic design requirements for safety-related structures were clarified:

a. Clause 6.4 on Seismic design was moved and combined with Clause 8 "Seismic analysis, design and dynamic considerations".

b. Clause 8 was revised to align with the design and detailing requirements of CSA A23.3.

9. Sub-clause 6.5.2.2 was added to supplement the requirements in Sub-clause 6.6.2.2 of CSA N291-08 (Sub-clause 6.5.2.1 in the 2015 edition of the standard) such that the design of bolted connections in members that are part of the seismic load resisting system are not governed by a brittle limit state.

10. Sub-clause 6.6.2.5 (6.5.2.5 in the 2015 edition of the standard) and Table 4 were updated to provide clarification on the load factors for steel components supporting piping or equipment which are designed to CSA N285.

11. Sub-clauses 6.6.3 and 6.6.4 consolidate and clarify the requirements for temperature limitations and loads induced by thermal effects in concrete structures.

12. Sub-clause 6.7.3 (6.6.5 in the 2015 edition of the standard) and Table 4 were updated to provide clarification on the load factors for metallic embedded parts supporting piping or equipment which are designed to CSA N285.

13. Sub-clause 6.6.6 was added to provide the requirements for anchorage to concrete.

14. Sub-clause 7.2.4.3.3 was updated to be applied to reinforcing bars partially embedded in concrete only. The standard was previously written to require inspection of all bent bars.

15. Clause 9 Aging Management was added to identify the requirements for aging management of safety-related structures.

16. Test method references were updated for Table 1 and Table 2: Clearer pointers to the reference standards were provided including the specific test methods

17. Annex C was removed as it is not part of this standard.

With respect to the changes listed above, Items 1, 2, 3, 7a, 7b, 8a, 10, 11, 12, 16 and 17 are either editorial in nature or provide additional clarification or guidance that does not introduce new requirements or modify previously existing requirements.

Item 4 is related to construction of concrete structures and the new recommendation it presents (for the internal temperature of mass concrete) is intended to additionally limit the effects of heat from hydration (e.g., cracks in the concrete during its curing). The requirements for mass concrete are specified in the referenced standards CSA A23.1-14/A23.2-14 [B.17-71]. The change recommends a best practice that applies during construction that is not safety significant for an existing structure, for which confirmation of no excessive cracking is achieved through other means such as in-service examinations.

Item 5 sets a requirement for the rebar splicing materials to comply with CSA W186-M1990 (R2012) [B.17-72]. Although this requirement is not in CSA N291-08, CSA W186-M1990 (R2007) [B.17-73] is referenced in it, making the latter code the governing document for rebar splicing. This and the fact that CSA W186-M1990 (R2012) and CSA W186-M1990 (R2007) are identical indicates that the change is for clarification and consequently it does not impact safety.

Item 6 introduces higher snow loads due to the change in requirement to design for a 100 year occurrence event instead of a 50-year occurrence event. With reference to the note under Sub-clause 6.3.1(a)(iv), the increase in snow load is 22%. This yields a snow load value of 2.14 kPa that is not safety significant in relation to the snow load value of 2.1 kPa that was used for the design of Pickering, as reflected in [B.17-74].

Item 8b removes the requirements of Clause 8.3 "Design provisions for concrete structures", which is now less restrictive. Hence, the change has no safety impact.

Item 9 imposes new requirements for bolted connections in members that are part of the seismic load resisting system. This item may have safety significance and requires further assessment since Pickering structures were not explicitly designed to meet these requirements. This is identified as **PSR2 CSA N291-15 Gap #1**.

Item 13 establishes explicit design requirements for concrete anchorage. In CSA N291-08, anchorage requirements were stated in general terms in Sub-clause 6.7.3.1, by making reference to Annex D of CSA A23.3. Corresponding requirements appear in Sub-Clause 6.6.6 of the 2015 code edition, which continues to refer to Annex D of CSA A23.3 for concrete anchorage requirements. Some new requirements are stated regarding non-safety related structures, post-installed anchors, operating temperature and the use of adhesive anchors that are either covered by other existing requirements, reflect standard OPG design practice or are not applicable to the current Pickering design. Therefore, there is no PSR2 gap.

Item 14 implements changes that make the requirements less restrictive than CSA N291-08, hence, it has no safety impact.

Item 15 introduces the new Clause 9 "Aging Management" (with sub-clauses) containing new requirements that are not in CSA N291-08. Clauses 9.1 and 9.2 are programmatic in nature. Clauses 9.3 and 9.4 require the effects of aging of safety related structures to be considered in the design by including safety margins. Clause 9.5 calls for design support on the related inspection and testing activities. Although these clauses do not provide specific criteria, they may be safety-significant. Further assessment is required since Pickering structures were not explicitly designed to meet these requirements and meeting these requirements could have significance for operation of the Pickering station beyond 2020. This is identified as **PSR2 CSA N291-15 Gap #2**.

The majority of the clauses in N291-15 relate to the design and construction of structures that have already been built and, as such, meeting these requirements is generally not impacted by the possibility of continued operation of Pickering beyond 2020. The only clauses that may be safety significant and that could have significance for operation of the Pickering station beyond 2020 are as follows:

- Clause 6.1.1(b) specifies that the analysis and design of safety-related structures shall include consideration of the design service life. Clause 6.9.2.1.4 specifies that non-metallic liner and joint sealant material shall have a minimum service life equal to the plant service life where repair, re-coating or replacement is not possible. These need to be assessed taking into consideration that operation of Pickering NGS beyond 2020 may exceed the service life assumed in the analysis and design. This is identified as **PSR2 CSA N291-15 Gap #3**.

- Clause 7.3 pertains to in-service examination, which is addressed by the PSR2 gap identified in OPG Report P-REP-03680-00024 R000 [B.17-69] relating to submission of Periodic Inspection Plans and Life Cycle Management Plans for a number of safety-significant civil structures to address fitness for service "to end of mission time" (which will need to be extended for Pickering operation past 2020).

- Clause 9 pertains to aging management, which is addressed by **PSR2 CSA N291-15 Gap #2**.

It is worth noting that CSA N291-15 references a number of other codes and standards for which PSR2 code reviews have been performed. The following codes are referenced in CSA N291-15 and were reviewed as part of the Pickering PSR2.

Code or Standard Number	Code or Standard Title
CSA N285.0-12	General Requirements for Pressure Retaining Systems and Components in CANDU Nuclear Power Plants
CSA N285.4-14	Periodic Inspection of CANDU Nuclear Power Plant Components

B.17.3 Compliance Summary for Pickering PSR2

There are three PSR2 CSA N291-15 gaps which relate to Safety Factor 1 (Plant Design):

1. Clause 6.5.2.2 of CSA N291-15 imposes new requirements for bolted connections in members that are part of the seismic load resisting system. Pickering NGS structures were not explicitly designed to meet these requirements and this is therefore identified as a PSR2 gap.

2. Clause 9 of CSA N291-15 contains new requirements related to aging management (including design provisions to account for aging) that are not in CSA N291-08 and that may have significance for operation of Pickering beyond 2020. Pickering structures were not explicitly designed to meet these requirements and this is therefore identified as a PSR2 gap.

3. Clauses 6.1.1(b) and 6.9.2.1.4 of CSA N291-15 state requirements for aspects of the design that are specifically based on the plant service life. Pickering structures were not explicitly designed or assessed in relation to the requirements of these clauses for operation beyond 2020. This is identified as a PSR2 gap.

There is also one PSR2 gap for CSA N291 related to submission of Periodic Inspection Plans and Life Cycle Management Plans for a number of safety-significant civil structures to address fitness for service "to end of mission time" (which will need to be extended for Pickering operation beyond 2020). The gap is related to Safety Factor 4 (Aging). As discussed in Section B.17.2.2, this issue is identified as a PSR2 gap in OPG Report P-REP-03680-00024 R000, "Pickering 5-8 Continued Operations Plan Review in Support of PNGS Periodic Safety Review 2 (PSR2)". Therefore, a duplicate gap has not been created under CSA N291-15.

B.18 CSA N285.6 Series-12, "Material Standards for Reactor Components for CANDU Nuclear Power Plants"

B.18.1 Background

The following, paraphrased from the scope of the CSA N285.6 section of the CSA N285.0/N285.6 Series-12 (including Updates No. 1 and No. 2) [B.18-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

The purpose of the CSA N285.6 series is to provide material, testing, and fabrication requirements for various CANDU reactor components and materials including:

- *Pressure tubes for use in CANDU fuel channels.*
- *Seamless zirconium alloy tubing for reactivity control units.*
- *Annealed seamless zirconium alloy tubing for liquid injection shutdown system (LISS) nozzles.*
- *Thin-walled, large-diameter zirconium alloy tubing.*
- *Non-destructive examination criteria for zirconium alloys.*
- *Zirconium alloy design data.*
- *Martensitic stainless steel for fuel-channel end fittings.*
- *Materials for supports for pressure-retaining items.*
- *Nickel-based alloy wire for fuel-channel spacers.*
- *Zirconium alloy wire.*
- *Zirconium alloy bars and rods for reactivity control units.*
- *Zirconium alloy sheet, strip and plate for reactivity control units.*

CSA N285.6 Series is directly relevant to Safety Factor 1 (Plant Design).

CSA N285.6 Series is identified in Appendix E.1 of the R04 Pickering Licence Conditions Handbook [B.18-2] as "Guidance or Criteria".

Since 2008, the CSA N285.6 Series has been published with CSA N285.0. The CSA N285.0/N285.6 Series-12 is the second edition of the CSA N285.0/N285.6 Series as it supersedes the previous series published in 2008. The N285.6-12 portion also supersedes previous editions of CSA N285.6 published in 2005 and 1988.

The preface to the N285.0/N285.6 Series-12 edition indicates that "CSA N285.6.5 was withdrawn in the 2005 edition of the CSA N285.6 Series as the material that it covered (heat-treated Zr-2.5Nb-0.5 Cu wire for fuel-channel spacers) is no longer used for new spacers."

The CSA N285.0/N285.6 Series-12 Impact Statement [B.18-3] provides a "Summary of significant changes from the previous edition" which identifies several changes to the Standard as described in Section B.18.2.2.

The results of PSR1 CSA N285.6 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.18.2. As identified in Reference [B.18-4], the Pickering PSR2 review of the CSA N285.6 Series-12 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.
- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.18.2 Compliance Assessment for Pickering PSR2

B.18.2.1 Application of PSR1 Reviews

The versions of the N285.6 Series (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

OPG Report NK30-REP-03680-00001 R000 [B.18-5] performed a code review of CSA N285.6-05 against OPG documentation (typically AECL specifications), and stated:

> *The conclusion of the review is that adoption of this standard has no impact on the original design basis of the Pickering B plant.*
>
> *No additional action is required to establish compliance with the Standard CSA N285.6-05 of the Pickering 'B' SOE [Safe Operating Envelope] systems after the planned refurbishment has been completed.*

N285.6-05 was comprised of ten standards:

- N285.6.1-05 Pressure tubes for use in CANDU fuel channels

- N285.6.2-05 Seamless zirconium alloy tubing for reactivity control units
- N285.6.3-05 Annealed seamless zirconium alloy tubing for liquid injection shutdown system (LISS) nozzles
- N285.6.4-05 Thin-walled, large diameter zirconium alloy tubing
- N285.6.6-05 Non-destructive examination criteria for zirconium alloys
- N285.6.7-05 Zirconium alloy design data
- N285.6.8-05 Martensitic stainless steel for fuel-channel end fittings
- N285.6.9-05 Materials for supports for pressure-retaining items
- N285.6.10-05 Nickel-based alloy wire for fuel-channel spacers
- N285.6.11-05 Zirconium alloy wire

OPG Report NK30-REP-03680-00001 R000 [B.18-5] excluded N285.6.1, 6.3, 6.6, 6.7, 6.8, 6.10, and 6.11 from code review as they cover requirements for fabrication, properties, and inspection of components that were planned to be replaced as part of Pickering B refurbishment with components meeting the latest versions of the standards. N285.6.9 was not assessed in detail based on an assessment that concluded that Pickering B generally meets the requirements of N285.6.9-05 [B.18-5].

N285.6.2-05 and N285.6.4-05 were reviewed clause-by-clause and 13 gaps were found which were classified as Acceptable Deviations (AD). Three ADs were dispositioned with having no safety significance, while additional assessment was required for 10 of the gaps [B.18-6]. These 10 ADs were addressed as part of the Final ISR report [B.18-7], in attached report [B.18-8]. The dispositions were provided in Appendix A.10 of [B.18-8] and A.10 Supplement 1-209. This assessment concluded that Pickering had an effective Reactor Assembly Aging Management Strategy and Plan and that there were no operational or aging related issues that would require components to be replaced. This combined with demonstrated compliance with the original design specifications, provides assurance that these gaps are acceptable.

These gaps relating to N285.6.2-05 and N286.5.4-05 are also applicable to Pickering Units 1,4. The disposition to the gaps as outlined above is equally applicable to Pickering 1,4, given the very similar design and material specifications between the units. Further detail regarding the plant specific designs and material is provided in Section B.18.2.2 below.

<u>Pickering Units 1,4</u>

The Pickering A Basis for Return to Service [B.18-9] identified CAN/CSA-N285.6-88 for review.

An assessment of CSA N285.6-88 was conducted in 2000 and documented [B.18-10]. This assessment performed clause-by-clause reviews of the nine standards in CAN/CSA-N285.6-88 (N285.6.1 to 6.9) against OPG documentation (typically AECL specifications). The review concluded that CSA N285.6.1 had no gaps; N285.6.2 had 3 ADs; N285.6.4 had 2 ADs; and

N285.6.7/6.8/6.9 had no gaps. Standards N285.6.3/6.5 are not applicable to Pickering Units 1,4 and Standard N285.6.6 is referenced by the other N285.6 standards whose evaluations demonstrate compliance with N285.6.6.

This comprehensive assessment against the 1988 version of the standards provides assurance that Pickering 1,4 complied with the original specifications and had no safety significant compliance gaps in 2000. However, the N285.6 series has subsequently been revised in 2005, 2008 and 2012. Hence, it is necessary to revisit the assessments performed to determine what changes have been made to the code, the impact and safety significance. This is addressed in Section B.18.2.2 below.

Darlington NGS

OPG Report NK38-REP-03680-10033 R000 [B.18-11] documents a review of CSA N285.6-08 against OPG documentation (typically AECL specifications) for the Darlington ISR, which identified 29 gaps against all of the 2008 versions of the standards listed above under the Pickering Units 5-8 review, except for N285.6.9-08. The report assessed some of these gaps to be minor and concluded the following:

> *The current version of CSA standard N285.6-08 "Material standards for reactor components for CANDU power plants", which contains ten individual standards, is the third edition which was published in June 2008. This series of material standards has been reviewed Clause-by-Clause and a number of gaps and deviations from the standards have been identified. A detailed analysis presented in the compliance discussion of each Clause presented in Appendix C indicates that the various noted deviations have little to no significant impact on the specified material property from being achieved in the fabricated components installed in the Darlington plant.*
>
> *Overall, the conclusion of the review is that adoption of this standard may have some impact on the original design basis of the Darlington plant due to the following factors associated with identified gaps:*
>
> *(a) The Limit of 0.0005 wt% hydrogen concentration in finished/autoclaved pressure tube material in Clause 7.9 of CSA N285.6.1-08;*
>
> *(b) The application UT-1 Standard requirements in Clause 7.1 of CSA N285.6.6-08 to seamless zirconium alloy reactivity control unit tubing;*
>
> *(c) The hydrostatic testing requirement for seamless small-diameter tubes in Clause 5.3 of CSA N285.6.2-08;*
>
> *(d) The application of UT-1 Standard requirements in Clause 7.1 of CSA N285.6.6-08 to seamless LISS nozzle tubing;*
>
> *(e) The application of UT-6 Standard requirements in Clause 7.6 of CSA N285.6.6-08 to seam-welded, thin-walled large-diameter tubes;*
>
> *(f) The axial and transverse yield strength requirements in Clause 7.1 and 7.2 of CSA N285.6.4-08 for seam-welded, thin-walled, large-diameter tubes;*

(g) The application of V-1 Standard requirements in Clause 4.1 of CSA N285.6.6-08 to seamless small diameter tubes;

(h) The application of V-2 Standard requirements in Clause 4.2 of CSA N285.6.6-08 to seam-welded, thin-walled large-diameter tubes;

(i) The application of V-4 Standard requirements in Clause 4.4 CSA N285.6.6-08 to pressure tubes;

(j) The noted differences in design data for Young's modulus, shear modulus and thermal expansion coefficient in the Darlington NGS design manual and those in Tables 1-4 in CSA N285.6.7-08;

(k) Methods and practices relating to chemical analysis of type 403 stainless steel end fitting material in Clause 5.2 of CSA N285.6.8-08;

(l) The noted differences in design data for thermal expansion coefficient and thermal conductivity in the Darlington NGS design manual and those in Annex A of CSA N285.6.8-08.

The notes, as shown in the affected clause of CSA N285.6-08 in Appendix C, indicate that the respective AECL specification provides more specific or more stringent requirements than the corresponding CSA Standard. These notes provide more detailed information than is available from the current Standard and should prove useful if fabrication of new components is required for refurbishment purposes.

OPG Report NK38-REP-03680-10104 R000 [B.18-12], "Darlington NGS Integrated Safety Review (ISR) - Final ISR Report", packages the N285.6-08 gaps into 3 issues, and classifies them all as Acceptable Deviations with no further action required, with the following statements:

Issue D021: Cleaning Solution Composition Limits [B.18-13]

In-service monitoring and inspections, along with planned component replacements and inspections, provide assurance that reactor components will continue to meet the design intent.

Issue D022: Non-destructive Testing of Reactor Components [B.18-14]

The variation from the modern requirements has no significant impact on the specified material properties and components identified in this issue.

Issue D023: Material Properties of Reactor Components [B.18-15]

The identified gaps are against the updated and new clauses from CSA N285.6-Series 08. Some critical components specified in the gaps (pressure tubes, calandria tubes, and end fittings) will be replaced as part of the refurbishment scope according to NK38-PLAN-01060-10003 R006. The design, fabrication, examination, testing and inspection of the replacement components will be in accordance with the latest versions of modern applicable codes and standards.

In addition, reactor components are subject to stringent aging management and inspection requirements as per N-PLAN-01060-10003 R006. Section 2.4 of N-PLAN-01060-10008 R000, "Reactor Components & Structures Life Cycle Management Plan: Technical Basis Document", discussed various degradation mechanisms and inspection requirements for reactivity mechanism Guide Tube (GT) assemblies in detail for the current as well as refurbished life of the reactor.

OPG Report NK38-REP-03680-10201 R001 [B.18-16], "ISR Open Issues and Acceptable Deviations – Adequacy Review", confirms the re-categorization of Darlington issues D021/D022/D023 as Acceptable Deviations with no further action required.

Subsequent to the review of N285.6-08, a Code Refresh review of CSA N285.6-12 against N285.6-08 was performed for Darlington in OPG Report NK38-REP-03680-10139 R000 [B.18-17] which concluded:

Review of the 2008 versus 2012 (including the September 2013 update, Update No.1) Code editions did not identify any significant changes. Any revisions identified involved relaxation in the code requirements. Consequently, the gaps identified in the original Code Review Report remain unchanged and the update of CSA N285.6-12 series of standards has no impact on Darlington's Integrated Safety Review.

As noted above, no code to code comparisons were made between the three versions of N285.6 used for Pickering A Return to Service or the Pickering B and Darlington ISRs (i.e., N285.6-88, -05, and -08). Therefore, Section B.18.2.2 below assesses and compares the differences between the plant designs and component materials used.

B.18.2.2 Application of Post PSR1 Reviews

As discussed above, a Code Refresh review of the changes in CSA N285.6-12 against N285.6-08 was performed as part of the Darlington ISR. In addition, a code-over-code review was conducted to evaluate changes between the 2012 versions of the standards and Update 1. The changes are documented in N-REP-00590-0520105, "Code-over-Code Report: CSA N285.0/CSA N285.6 Series For Year 2014" [B.18-18]. This code update only included changes to N285.6.6-12 which are summarized as follows:

1. Clause 4.3.2: clarification on inspection requirements for external and internal surfaces of tubular products.

2. Clause 4.3.3: acceptance criteria for "inspection tooling scratches" changed to "linear type scratches" and clarified wording to align with Non-Destructive Examination terminology and requirements.

The review in reference [B.18-18] concluded that these changes only provided additional clarification.

Update No. 2 (2014) to CSA N285.0/N285.6 included the following changes to N285.6 Series-12, paraphrased from the Impact Statement for Publication [B.18-3]:

1. *Two new material standards for materials used in Reactivity Control Units (RCUs) that were not covered by the existing standards were added, as follows:*

    a. *N285.6.12-14 Zirconium alloy bars and rods for reactivity control units*

    b. *N285.6.13-14 Zirconium alloy sheet, strip and plate for reactivity control units*

2. *A correction to the referenced clause in clauses 7.3.3 of standard N285.6.6-12.*

Hence, the above assessments support the conclusion that no significant changes to the previously existing content in N285.6 occurred between 2008 (Darlington ISR version) and 2012 version (used for this evaluation), including Updates No. 1 (2013) and Update No. 2 (2014). The two new standards introduced in Update No. 2 are addressed under their respective sub-sections below.

Although the three OPG plants (Darlington, Pickering 1,4 and Pickering 5,8) have significant differences in design and component ages, there are many similarities between the plants in terms of material specifications for reactor components relating to N285.6. Pickering 1,4 units underwent a Fuel Channel Replacement Program starting in the mid-1980s, and both Pickering 1,4 and Pickering 5-8 have made several changes to reactor in-core components, e.g., completely replacing in-core flux monitor assemblies. In addition, a combination of maintenance and inspections have resulted in replacement of several additional in-core components (e.g., Fuel Channels, Calandria Tubes, Garter Springs). These activities provide assurance of fitness for service and assurance that degradation mechanisms are known and monitored [B.18-19]. Further, all units have active Life Cycle Management Plans (LCMPs) for reactor components and structures [B.18-20], and fuel channels [B.18-21].

The CSA standard material requirements are implemented in Technical Specifications that are used for procurement. These specifications augment existing requirements usually specified by American Society for Testing of Materials (ASTM) or American Society of Mechanical Engineers (ASME). Hence, the approach to this incremental review is to compare the associated material/component specifications for each plant against the CSA requirements.

The sub-sections below summarize the applicable specifications for each plant (Pickering 1,4; Pickering 5-8 and Darlington) and assesses their level of compliance against the current CSA N285.6 series of material requirements. The Darlington references are identified so that they can be compared against the Pickering specifications.

<u>CSA N285.6.1-12: Pressure Tubes for Use in CANDU Fuel Channels</u>

CSA N285.6.1-12 covers the manufacturing and property requirements for seamless, cold-worked and stress-relieved Zr-2.5Nb pressure tubes. The three stages of fabrication are: (1) the preparation of ingots by consumable electrode melting and hot forging of these ingots into billets; (2) the preparation of the billets into seamless shells, and the cold working of the extruded shells into tubes; (3) the cleaning, caustic washing, autoclaving, straightening, and inspection of the tubes. A similar set of technical specifications was used in the fabrication and final processing of the pressure tubes for each plant. These are identified below:

Pickering 1,4 [B.18-10]	Pickering 5-8 [B.18-27][B.18-28]	Darlington [B.18-11]
Unit 1 • TS-44-31110-17 R0 [B.18-22] (manufacturing), based on TS-XX[16]-31110-5 R7 [B.18-24] • TS-XX-31110-4 R6 [B.18-23] (cleaning and stress relief) **Unit 4** • TS-XX-31110-5 R9 [B.18-26] (manufacturing) • TS-XX-31110-4 R6 [B.18-23] (cleaning and stress relief)	• TS-XX-31110-5 R3 [B.18-25] (manufacturing) **Unit 5** • TS-XX-31110-4 R1 per [B.18-27] (cleaning and stress relief) **Units 6,7,8** • TS-XX-31110-8 R1 per [B.18-27] (cleaning and stress relief)	• TS-XX-31110-5 R7 [B.18-24] (manufacturing) • TS-XX-31110-4 R5 [B.18-29] (cleaning and stress relief)

The Darlington review performed and detailed a comparative review of material and mechanical properties between the various specifications, compiled in Tables 3 and 4 of [B.18-11]. The clause by clause review of this standard for Darlington [B.18-11] identified the following gaps:

1. Clause 4.5, Limits on halogen and sulphur contents in final cleaning solutions for pressure tubes.

2. Clause 7.9, Limit on hydrogen concentration in autoclaved pressure tube material.

3. Clause 7.11, Visual inspection of pressure tubes to CSA N285.6.6-08 Standard V-4.

Gap 1 arises because the AECL specifications used for Darlington [B.18-24], [B.18-29] do not include any limits on halogen and sulphur contents in the cleaning solutions. Gap 2 is the result of the new requirement in Clause 7.9 which limits the measured hydrogen concentration in autoclaved pressure tube material to a maximum of 0.0005 wt % (5 ppm). Gap 3 arises because the 2008 Standard in Clause 7.11(a) limits the scratch length to a maximum of 25 mm whereas the original AECL specification allows a maximum length of 150 mm (note, this is now addressed in Clause 4.3.3 of the 2012 version of N285.6.6-12). For Material/manufacturing requirements per TS-XX-31110-5 above, Pickering Unit 1 and Darlington are the same (R7 - 1979). For Pickering Unit 4, a more recent revision (R9 -1988) was used. This new version is more comprehensive and has some tighter specifications. Therefore, Clause 7.11 would not result in a gap for Pickering Unit 4. For Pickering 5-8, an older version of the specification was used (R3-1977). The revisions between 1977 and 1981 were relatively minor as the manufacturing process for the installed pressure tubes was nearly identical, with the most significant change being that a post-heat treat quenching requirement was added [B.18-30]. This is not a requirement of the CSA standard and does not result in an additional gap. Additionally, per Figure 3 of [B.18-30], the comparison of measured mechanical properties and corrosion data demonstrates minimal impact.

[16] 'XX' is included in the actual document number. The specific plant of application is identified in the document Revision and/or Issue # summary.

For pressure tube finishing, including inspection, TS-XX-31110-4 was used for Pickering Units 1,4; Pickering Unit 5 and Darlington. Pickering Units 6,7,8 used TS-XX-31110-8 which was subsequently superseded by TS-XX-31110-4 R5 [B.18-29]. The Darlington review of Clause 7.11 [B.18-11] is also applicable to these specifications, and the above gap 3 is also applicable to Pickering 5-8.

Based on a comparison of the various specifications against the standard, it is concluded that the issues identified in the Darlington ISR review that led to Darlington gaps are also applicable to Pickering and that there are no additional Pickering specific gaps. These Darlington gaps were evaluated in [B.18-13], [B.18-14] and [B.18-15] with resolutions provided. All gaps were confirmed to be Acceptable Deviations with low safety significance, identifying that on-going surveillance per the Fuel Channel LCMP [B.18-20] provides adequate assurance of continued fitness for service. These conclusions are also applicable to Pickering and therefore the Darlington issues are not PSR2 gaps.

As already noted, Darlington completed a clause by clause review against the 2008 version of the standard and also determined that there are no significant incremental requirements between the 2008 and 2012 versions of the standard.

There are no Pickering PSR2 gaps for CSA N285.6.1-12.

CSA N285.6.2-12: Seamless Zirconium Alloy Tubing for Reactivity Control Units

CSA N285.6.2-12 addresses the manufacturing and property requirements for seamless, zirconium alloy tubing used in the fabrication of reactivity control units. The AECL specifications that applied to the manufacture are identified below.

Pickering 1,4 [B.18-10]	Pickering 5-8 [B.18-5]	Darlington [B.18-11]
• NP-M-653 R1 [B.18-31]	• TS-XX-31700-6 R0 [B.18-32]	• TS-XX-31700-6 R0 [B.18-32]

A list of seamless Zircaloy-2 tubing used for reactivity units is presented in Table 5 of [B.18-11]. Tabulations of the mechanical property and chemical specification requirements according to the above-mentioned AECL specification for Darlington, relevant ASTM Standards and N285.6.2-08 requirements for Zircaloy-2 tubing used for reactivity units are presented in Tables 4 and 6 of [B.18-11]. Pickering 1,4 used NP-M-653 R1 which references ASTM B350. Since N285.6.2-12 now references ASTM 350, the chemical properties are consistent with the standard.

The Darlington clause by clause review of this standard identified the following gaps in meeting the requirements of CSA N285.6.2-08:

1. Clause 3.5: Limits on halogen and sulphur contents in final cleaning solutions for seamless reactivity control unit tubing.

2. Clause 5.3: Hydrostatic testing of seamless small-diameter tubes.

3. Clause 5.4: Visual inspection of seamless small-diameter tubes to CSA N285.6.6-0

Standard V-1.

4. Clause 5.5: Ultrasonic inspection of seamless small-diameter tubes to CSA N285.6.6-08 Standard UT-1.

Gap 1 arises because the specified maximum limits for halogen and sulphur are higher than the limits specified in Clause 3.5 of N285.6.2-08. However, this gap in meeting the specified limits is considered minor, and should have no impact on the fabricated seamless Zircaloy-2 tubing meeting the requirements for the reactivity control unit application [B.18-11]. Gap 2 arises because Reference [B.18-31] does not specify hydrostatic testing for seamless small diameter tubing and the requirements in Clause 5.3 of the Standard are not met. Gap 3 relates to no explicit specification of boroscope or videoscope methods required by Clause 4.1.2 of N285.6.6-12. Gap 4 arises because Reference [B.18-31] does not include an ultrasonic inspection for seamless reactivity control unit tubing. It should be noted that these gaps were also identified in the Pickering B ISR [B.18-5] and the gaps are also applicable to PSR2. As noted, in Section B.18.2.1, above, Pickering 1,4 assessed NP-M-653 Rev. 1 against the 1988 version of CSA N285.6.2 and issues associated with Darlington gaps 2, 3 and 4 were are also identified. No issues relating to cleaning solutions were identified, however, given that the tighter specification now exists, it can be surmised that this would have also been a gap for the older Pickering 1,4 components.

Therefore, based on a comparison of the various specifications against the standard, it is concluded that the gaps identified for Darlington are also applicable to Pickering and there are no additional Pickering specific gaps. These gaps were evaluated in [B.18-13] and [B.18-14] with resolutions provided. All gaps were confirmed to be Acceptable Deviations with low safety significance, identifying that on-going surveillance per the component LCMP [B.18-20] provides adequate assurance of continued fitness for service. These conclusions are also applicable to Pickering and therefore the Darlington issues are not PSR2 gaps.

As already noted, Darlington has done a clause by clause review against the 2008 version of the standard and determined that there are no significant incremental requirements between the 2008 and 2012 versions of the standard.

There are no Pickering PSR2 gaps for CSA N285.6.2-12.

CSA N285.6.3-12: Annealed Seamless Zirconium Alloy Tubing for Liquid Injection Shutdown Systems (LISS) Nozzles

CSA N285.6.3-12 covers the manufacturing and property requirements for seamless zirconium alloy tubing used in fabrication of LISS nozzles. The applicable AECL specifications are identified below. Note, there is no LISS system in Pickering 1,4.

Pickering 1,4	Pickering 5-8	Darlington [B.18-11]
• Not Applicable to Pickering 1,4	• TS-XX-31761-5 R0 [B.18-33]	• TS-XX-31761-5 R1 [B.18-34] (Refers to ASTM B350-73)

Tabulations of the mechanical property and chemical specification requirements according to the above-mentioned AECL specification for Darlington, relevant ASTM Standards and N285.6.3-08 requirements for Zircaloy-2 tubing used for LISS nozzles are presented in Tables 4 and 6 of [B.18-11]. A review of Pickering 5-8 history dockets [B.18-35] and [B.18-36] against the ASTM B 350 requirements in Table 6 of [B.18-11] confirms that all chemical specifications were the same as or more stringent than the ASTM requirements.

The Darlington review identified the following gaps in meeting the requirements of CSA N285.6.3-08:

1. Clause 3.5: Limits on halogen and sulphur contents in final cleaning solutions for seamless LISS nozzle tubing.

2. Clause 5.1: Ultrasonic inspection of seamless LISS nozzle tubing to CSA N285.6.6-08 Standard UT-1.

3. Clause 5.3: Liquid Penetrant examination procedure for seamless LISS nozzle tubing.

Gap 1 relates to Section 5.7.3 of Reference [B.18-34] where the limits are higher than the limits specified in Clause 3.5 of N285.6.3-08. A review of [B.18-33] confirms that this issue is also applicable to Pickering 5-8. Similarly, gap 2 is applicable to Pickering 5-8, requiring an explicit procedure or acceptance criteria for the ultrasonic inspection that is in accordance with Standard UT-1 in Clause 5.1 of N285.6.6-08. Gap 3 is also applicable to Pickering 5-8 where the liquid penetrant inspection method is not specified in [B.18-33].

Therefore, based on a comparison of the various specifications against the standard, it is concluded that the gaps identified for Darlington are also applicable to Pickering and there are no additional Pickering specific gaps. These gaps were evaluated in [B.18-13] and [B.18-14] with resolutions provided. All gaps were confirmed to be Acceptable Deviations with low safety significance, identifying that on-going surveillance per the component LCMP [B.18-20] provides adequate assurance of continued fitness for service. These conclusions are also applicable to Pickering 5-8 and therefore the Darlington issues are not PSR2 gaps.

Darlington has done a clause by clause review against the 2008 version of the standard and determined that there are no significant incremental requirements between the 2008 and 2012 versions of the standard.

There are no Pickering PSR2 gaps for CSA N285.6.3-12.

CSA N285.6.4-12: Thin-Walled, Large-Diameter Zirconium Alloy Tubing

CSA N285.6.4-12 covers the manufacturing and property requirements for thin-walled, large-diameter tubes that are used for calandria tubes and guide tubes for reactivity control mechanisms. The AECL technical specifications used for fabrication of the tubes are identified below:

Pickering 1,4 [B.18-10]	Pickering 5-8	Darlington [B.18-11]
• NP-M-601 R1 (Calandria Tubes) [B.18-37] • NP-M-653 R1 (Guide Tubes) [B.18-31]	• TS-XX-31230-2 R4 (Calandria Tubes) [B.18-38] • TS-XX-31700-6 R0 (Guide Tubes) [B.18-31]	• TS-38-31231-1 R1 (Calandria Tubes) [B.18-39] • TS-38-31700-14 R0 (Guide Tubes) [B.18-40]

The mechanical property and chemical specification requirements for the above Darlington specifications are presented in Tables 4 and 7 [B.18-11], respectively. The chemical composition of materials used for Pickering 5-8 is the same as those used for Darlington. Pickering 1,4 assessed the NP-M-601 R1 specification against N285.6.4-88 in Reference [B.18-10]. The review compared the NP-M-601 R1, ASTM B350 requirements for Alloy R60802 against N285.6.4-88 and showed all requirements to be met. The same conclusion was applicable to NP-M-653 R1 which also references ASTM B350. N285.6.6-12 now references ASTM 350, hence, chemical properties for Pickering materials are consistent with the standard.

The Darlington clause-by-clause review identified the following gaps in meeting the requirements of CSA N285.6.4-08:

1. Clause 3.5: Limits on halogen and sulphur contents in final cleaning solutions for seam-welded thin-walled large-diameter tubes.

2. Clause 7.1 Transverse yield strength requirements for seam-welded, thin-walled large-diameter tubes.

3. Clause 7.2: Axial yield strength requirements for seam-welded, thin-walled large-diameter tubes.

4. Clause 7.5 Visual inspection of thin-walled, large-diameter tubes to CSA N285.6.6-8 Standard V-2.

5. Clause 7.6: Ultrasonic inspection of thin-walled, large-diameter tubes to CSA N285.6.6-08 Standard UT-6.

Gap 1 relates to the specified maximum limits for halogen and sulphur and has already been identified and addressed above. This gap is equally applicable to all Pickering units.

Gap 2 arises because the transverse room temperature 0.2% yield strength specified in Section 5.4.3 of [B.18-39] is lower than that specified in Clause 7.1 of N285.6.4-08. Similarly gap 3 relates to the axial room temperature 0.2% yield strength specified in Section 5.4.3 of Reference [B.18-39] being lower than that specified in Clause 7.1 of N285.6.4-08. The Pickering 1,4 specifications identified above are below the limits in the standard for both Calandria Tubes and Guide Tubes. The Pickering 5-8 specifications are equivalent to those in the standard for Calandria Tubes and lower for Guide Tubes. For Pickering 1,4, the ISR review against Clause 5.3.2.2 of the N285.6.4-88 review [B.18-10] indicated that history docket test results are also below the standard requirements. However, this was assessed as being acceptable in [B.18-10] when accounting for actual wall thickness and material strengthening due to irradiation. Incorporating these factors would result in the standard requirements being exceeded. Since Pickering 5-8 has the same specified Guide Tube mechanical properties as Pickering 1,4, the same Pickering 1,4 conclusions are applicable to Pickering 5-8. Additionally, the N285.6.7-12 (*Zirconium Alloy Design Data*) yield strength requirement to be used for N285.6.4 finished material is 240 MPa, which is lower than the 320 MPa in N285.6.4-12. All of the Pickering specifications meet the 240 MPa requirement. Given the above, the Pickering components satisfy the requirements of the standard and are therefore acceptable. Hence, gaps 2 and 3 above are not PSR2 gaps for Pickering.

Gap 4 relates to visual surface examination of thin-walled, large-diameter tubes not explicitly requiring boroscope or videoscope inspections. Gap 5 arises because the ultrasonic inspection specified did not meet the requirements of Standard UT-6 in N285.6.6-08. These gaps are also applicable to Pickering.

Therefore, based on a comparison of the various specifications against the standard, it is concluded that gaps 1, 4 and 5 identified for Darlington are also applicable to Pickering and there are no additional Pickering specific gaps. These gaps were evaluated in [B.18-13] and [B.18-14] with resolutions provided. All gaps were confirmed to be Acceptable Deviations with low safety significance, identifying that on-going surveillance per the component LCMP [B.18-20] provides adequate assurance of continued fitness for service. These conclusions are also applicable to Pickering and therefore the Darlington issues are not PSR2 gaps.

As already noted, Darlington has done a clause by clause review against the 2008 version of the standard and determined that there are no significant incremental requirements between the 2008 and 2012 versions of the standard.

There are no Pickering PSR2 gaps for CSA N285.6.4-12.

CSA N285.6.6-12: Non-Destructive Examination Criteria for Zirconium Alloys

CSA N285.6.6-12 covers the non-destructive examination criteria for zirconium alloys. AECL technical specifications relevant for this Standard are those already discussed in the sections above for the reviews of N285.6.1, N285.6.2, N285.6.3 and N285.6.4. The reviews of those standards have already been addressed above. Hence, no further review is required and no PSR2 gaps have been identified.

CSA N285.6.7-12: Zirconium Alloy Design Data

CSA N285.6.7-12 addresses zirconium alloy design data and there is only one clause in this standard. The minimum tensile properties specified in N285.6.1, N285.6.2, N285.6.3 and N285.6.4 presented in Table 1 of the current Standard are compared with the original AECL specifications tabulated in Table 4 of [B.18-11]. Reference [B.18-30] provides the yield and ultimate strengths for all Pickering unit pressure tubes (P1,4 and P5-8). In all cases the requirements in Table 1 of N285.6.7-12 are met. Pickering 5-8 tube stress intensity is included in the Fuel Channel Design Manual, Figure 13 of [B.18-27]. This figure demonstrates that the allowable stresses in Table 1 of N285.6.7-12 for the R60901 Alloy are met for the temperatures.

For N285.6.2-12, N285.6.3-12 and N285.6.4-12 each of the applicable component's mechanical strength requirements have been assessed in their respective code reviews above. Per [B.18-10], all other physical properties are included in References 14, 15 and 16 of that report.

There are no Pickering PSR2 gaps for CSA N285.6.7-12.

CSA N285.6.8-12: Martensitic Stainless Steel for Fuel-Channel End Fittings

CSA N285.6.8-12 covers martensitic stainless steel forged blanks used in fuel channel end fittings. The AECL technical specifications used in the fabrication of the stainless steel forged blanks and the end fittings are identified below.

Pickering 1,4 [B.18-10]	Pickering 5-8 [B.18-27]	Darlington [B.18-11]
• AECL NPE-610 per [B.18-19] (original Unit 1 only) • TS-XX-31120-2 R2 [B.18-42] (Referenced in [B.18-10]) • TS-XX-31120-4 R2 (blanks) [B.18-41]	• TS-XX-31120-2 R2 [B.18-42] • TS-XX-31120-4 R0 (blanks) [B.18-43]	• TS-XX-31120-3 R1 [B.18-44] • TS-XX-31120-4 R2 (blanks) [B.18-41]

Tabulations of material property requirements for AECL specification TS-XX-31120-4 for blanks, relevant ASTM Standards and N285.6.8-08 requirements for type 403 stainless steel fuel channel end fittings, are presented in Table 9 and 10 of [B.18-11], respectively. The Darlington clause by clause review of this standard identified the following gaps in meeting the requirements of CSA N285.6.8-08:

1. Clause 4.3: Minimum temperature for tempering of type 403 SS end fitting blanks;
2. Clause 5.2: Methods and practices for chemical analysis of type 403 SS end fitting material;
3. Annex A design data.

Gap 1 relates to the specified heat treatment of blanks. Section 4.5 of [B.18-41] calls for a minimum tempering temperature of 593°C as opposed to the minimum temperature of 600°C specified in Clause 4.3 of N285.6.6-08. This is the same requirement in the 2012 version of the standard and this gap is also applicable to Pickering 1,4 and 5-8. However, this gap is not considered to have a significant impact since the mechanical properties in the AECL specification and the CSA Standard are the same [B.18-11]. Gap 2 arises because Sections 4.3 and 5.2 of [B.18-41] do not specify explicitly what methods and practices relating to the chemical analysis of the type 403 SS end fitting material are to be followed as required by Clause 5.2 of N285.6.6-08 and -12. This gap is also applicable to Pickering. Gap 3 relates to Darlington design data being slightly different than that in Annex A of the standard. The specifications in Annex A have not changed between the 2008 and 2012 versions of the standard and are also applicable to Pickering. However, the Pickering 1,4 code review [B.18-10] against the 1988 standard identified the units to be indirectly compliant, citing the Design Specification as being sufficient. Hence, Darlington gap 3 is only applicable to Pickering 5-8.

Therefore, based on a comparison of the various specifications against the standard, it is concluded that the gaps identified for Darlington are all applicable to Pickering, with exception of gap 3, which is not applicable to Pickering 1,4. There are no additional Pickering specific gaps. These three gaps were evaluated in [B.18-15] with resolutions provided. The gaps were confirmed to be Acceptable Deviations with low safety significance, identifying that on-going surveillance per the reactor component LCMP [B.18-20] provides adequate assurance of continued fitness for service. These conclusions are also applicable to Pickering and therefore the Darlington issues are not PSR2 gaps.

Therefore, there are no Pickering PSR2 gaps for CSA N285.6.8-12.

CSA N285.6.9-12: Materials for Supports for Pressure-Retaining Items

CSA N285.6.9-12 covers the material for supports for pressure-retaining items in nuclear power plants, and includes the materials permitted by Article NF-2000, in ASME Section III. This applies to all pressure-retaining nuclear systems. Article NF-2000 establishes general requirements for materials for use in supports to meet the strength specifications required by ASME/ASTM. The topics covered in the standard address requirements for material certification, removal of sample coupons from the various fabricated forms of the material and testing procedures to verify material properties.

The N285.6.9 standard did not exist when either Pickering plant was designed or built. Assessments were performed for Pickering A Return to Service [B.18-10] and Pickering B ISR [B.18-5] against the 1988 and 2005 versions of N285.6.9 respectively. Both reviews identified that the stations were indirectly compliant with the requirements by virtue of their compliance with the ASME requirements. The assessments demonstrate that compliance with the ASME code requirements imposed the applicable ASTM requirements. There have not been any significant changes to this standard since the Pickering 1,4 or Pickering 5,8 code reviews have been done as part of PSR1. Therefore, there are no PSR2 gaps relating to CSA N285.6.9-12.

CSA N285.6.10-12: Nickel-Based Alloy Wire for Fuel-Channel Spacers

CSA N285.6.10-12 covers nickel-based alloy wire for fuel channel spacers/garter springs. The AECL technical specifications used in the fabrication of the garter spring type fuel channel annulus spacers are identified below. Note, Pickering 5-8 did not use Inconel X-750 spacers for most of the original installation. However, several Unit 7 and Unit 8 fuel channels were replaced pre-service with tight fitting X-750 spacers. Fuel Channel replacements have also used the X-750 spacers.

Pickering 1,4 [B.18-10]	Pickering 5-8	Darlington [B.18-11]
• TS-XX-31160-3 R2 [B.18-45] (Refers to ASTM B351-79)	• Used Zirconium alloy per withdrawn CSA N285.6.5-05 • TS-XX-31160-3 R2 [B.18-45], used for limited number of specific Unit 7 and 8 channels and for channel replacements.	• TS-XX-31160-3 R2 [B.18-45] (Refers to ASTM B351-79)

The Clause-by-Clause review of this standard for Darlington identified only one gap in meeting the requirements of CSA N285.6.10-08:

1. Clause 3.6: Limits on halogen and sulphur content in cleaning solutions for X-750 spacer wire.

The gap arises because Section 5.5 of Reference [B.18-45] does not contain any specific requirements for halogen and sulphur contents in the final cleaning solution. Given that Pickering Units 1,4 and Units 7,8 used the same specification, this Darlington gap is also applicable. However, this gap in meeting the requirement of Clause 3.6 of N285.6.10-08 was considered minor and to have no significant impact on the nickel-based alloy wire meeting the design requirements for the spacer application in the Darlington reactors [B.18-11]. There are no additional Pickering 1,4 gaps relating to this standard.

This gap was evaluated in [B.18-13] with a resolution provided and confirmed to be an Acceptable Deviation with low safety significance. This conclusion is also applicable to Pickering and therefore the Darlington issue is not a PSR2 gap.

There are no Pickering PSR2 gaps for CSA N285.6.10-12.

CSA N285.6.11-12: Zirconium Alloy Wire

CSA N285.6.11-12 covers zirconium alloy wire used as filler wire in the fabrication of seam-welded, thin-walled, large-diameter tubes and as the girdle wire in the current design annulus fuel channel spacers. Zirconium wire is used in the fabrication of seam-welded, thin-walled, large-diameter Zircaloy-2 tubes and in the fabrication of garter springs. This standard did not exist at the time Pickering 1,4 or 5-8 were designed and built. There were no specific specifications for zirconium wire; rather it is used as required in the respective component specifications. Examples of specifications are included in the table below.

Pickering 1,4 [B.18-10]	Pickering 5-8	Darlington [B.18-11]
• TS-XX-31160-3 R2 (spacers) [B.18-45] (Refers to ASTM B351-79)	• TS-XX-31160-1 R5 (spacers) [B.18-46] • TS-XX-31230-2 R4 (Calandria Tubes) [B.18-35] • TS-XX-31700-6 R0 (Guide Tubes) [B.18-31]	• TS-XX-31160-3 R2 (spacers) [B.18-45] (Refers to ASTM B351-79) • TS-38-31231-1 R1 (Calandria Tubes) [B.18-39] • TS-38-31700-14 R0 (Guide Tubes) [B.18-40]

The material requirements in CSA N285.6.11-12 are the same as those in N285.6.4-12 requiring Zirconium wire properties to meet ASTM B351 Grade R60802 or R60804. The ingot elemental composition is the same as those requirements in N285.6.4-12. Table 8 of [B.18-11] compares the chemical specifications in N285.6.11-08 (same as 2012) to ASTM and the AECL specifications. Specifications for Oxygen, Lead, Tantalum and Vanadium are not provided in the ASTM and AECL requirements. However, this deviation was identified in the Pickering B ISR [B.18-5] for Clause 4.2 of CSA N285.6.4-05 and in the Darlington review of CSA N285.6.11-08 [B.18-11] and dispositioned as not having any consequential impact on the mechanical design.

The Darlington clause-by-clause review of this standard identified only one gap in meeting the requirements of CSA N285.6.11-08:

1. Clause 3.3: Limits on halogen and sulphur contents in cleaning solutions for zirconium alloy wire.

This gap arises because the specified maximum limits for halogen and sulphur in cleaning solutions are higher than the limits specified in Clause 3.3 of N285.6.11-12. This Darlington issue is also applicable to Pickering. However, this gap in meeting the specified limits is minor and should have no impact on the Zircaloy-2 wire meeting the design requirements for the filler wire per [B.18-11].

This gap was evaluated in [B.18-13] with a resolution provided and confirmed to be an Acceptable Deviation with low safety significance. This conclusion is also applicable to Pickering and therefore the Darlington issue is not a PSR2 gap.

There are no Pickering PSR2 gaps for CSA N285.6.11-12.

CSA N285.6.12-14: Zirconium Alloy Bars and Rods for Reactivity Control Units and CSA N285.6.13-14: Zirconium Alloy Sheet, Strip and Plate for Reactivity Control Units

The introduction of the two new standards (N285.6.12-14/.6.13-14) relating to zirconium material properties used in new reactivity mechanisms does not introduce any incremental requirements that have not already been addressed in the above standard reviews related to reactivity control mechanisms. This is because these standards were established to codify existing AECL specifications in CSA requirements and to document the acceptability of materials that are currently in use and that have ASTM specifications for the material. In both standards, the ASTM specifications are augmented with additional specific composition requirements. These same requirements exist in other CSA N285.6-12 standards and are already assessed above. The standards also cross-reference the specific inspection requirements that are also included in the component specifications and N286.6.6-12 standard that is also addressed above. Hence, the introduction of these two new standards has no impact on the existing Pickering plant and there are no Pickering PSR2 gaps.

B.18.3 Compliance Summary for Pickering PSR2

There are no PSR2 gaps for CSA N285.6 Series-12. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with CSA N285.6 Series-12.

B.19 ASME B31.1 (2014), "Power Piping"

B.19.1 Background

The following excerpts paraphrased from the Scope of ASME B31.1-14 [B.19-1] provide a brief overview of the purpose of the standard and the requirements expressed therein:

> *ASME B31.1 has been developed considering the needs for applications that include piping typically found in electric power generating stations, in industrial and institutional plants, geothermal heating systems, and central and district heating and cooling systems.*
>
> *ASME B31.1 prescribes requirements for the design, material, fabrication, erection, test, inspection, operation, and maintenance of power piping systems. Piping as used in this Code includes pipe, flanges, bolting, gaskets, valves, pressure-relieving valves/ devices, fittings, and the pressure containing portions of other piping components, whether manufactured in accordance with Standards listed in Table 126.1 or specially designed. It also includes hangers, supports and other equipment necessary to prevent overstressing the pressure containing components.*

ASME B31.1 is relevant to Safety Factor 1 (Plant Design).

ASME B31.1 is identified in Appendix E.1 of the R04 Pickering Licence Conditions Handbook [B.19-2] as "Guidance or Criteria".

ASME B31.1-14 [B.19-1] supersedes numerous previous editions of B31.1, most recently issued in 2012, 2010 and 2007. The origins of ASME B31.1 date back to the 1920s, with the first official edition published in 1935. The American Society of Mechanical Engineers [B.19-3] identifies the key changes to ASME B31.1-14 which are discussed under Section B.19.2.2 below. Also discussed in Section B.19.2.2, OPG has established the CNSC accepted process of using the Reedy Engineering ASME Code Reconciliation Report to ensure ongoing compliance with ASME B31.1, and, in parallel, there is a yearly examination of any incremental (Code-over-Code) review requirements which ensure that significant technical changes to B31.1 will be applied, as appropriate, for modifications to existing Pickering NGS power piping going forward.

The results of PSR1 ASME B31.1 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.19.2. As identified in Reference [B.19-4], the Pickering PSR2 review of ASME B31.1 (2014) is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.
- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.19.2 Compliance Assessment for Pickering PSR2

B.19.2.1 Application of PSR1 Reviews

The versions of ASME B31.1 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

No review was performed against ASME B31.1 as part of the Pickering B ISR. OPG Report NK30-REP-03680-00001 R000, "Pickering NGS-B Integrated Safety Review - Plant Design Safety Factor" [B.19-5] did not review ASME B31.1. Nevertheless, OPG Report N-REP-01903.1-10000 R017, "ASME Code Reconciliation for Material, Parts and Components" [B.19-6] identifies all the significant changes in ASME B31.1 up to and including the 2014 edition. N-REP-01903.1-10000 R017, known as the Reedy Report, is used as a reference at OPG when designing pressure boundary repairs, replacements and modifications. As will be discussed under Section B.19.2.2 below, OPG has established the process of using the Reedy Report to ensure compliance with ASME pressure boundary codes and this process has been accepted by the CNSC. As discussed in Section B.19.2.2, the Engineering Change Control (ECC) process ensures that significant technical changes to B31.1 will be applied, as appropriate, for modifications going forward in accordance with OPG governance. Application of B31.1-14 to the as-built design is also discussed under Section B.19.2.2. The conclusion is that there are no PSR2 gaps for Pickering Units 5-8 compliance with ASME B31.1-14.

Pickering Units 1,4

OPG Report NA44-REP-00584.1-10001 R000, "Pickering A ASME Codes Reconciliation - Pickering A Return to Service" [B.19-7] was prepared to:

> *Provide a reconciliation of the ASME Code requirements between the ASME Section VIII and B31.1 1992 Editions, and Section III 1995 Edition to the latest Code 1998 Editions including the 1999 Addenda.*

The ASME Codes Reconciliation found no major impacts from the review against the 1992 edition of ASME B31.1 (including 1999 Addenda). OPG Letter NA44-CORR-00531-00190 R000, "ASME Codes Reconciliation - System and Component Modifications (Pickering NGS-A, Units 1-4)" [B.19-8] states:

> *For modifications, including associated equipment and material, CNSC indicated their acceptance of a case-by-case, code specific, reconciliation. In response, OPG has developed a master ASME codes reconciliation report, which addresses all code changes that impact Pickering A systems' design, equipment, and material. This codes reconciliation report (i.e., OPG Report No. NA44-REP-00584.1-10001, Rev. 00, 30 August 2000), entitled "Pickering A ASME Codes Reconciliation," is enclosed for your information and use….*

The code reconciliation report was based primarily on a technical report, prepared by Reedy Engineering, entitled "ANSI/ASME Code Reconciliation for Replacement Material, Parts, and Components," Rev. 9, 7 January 2000. In addition, various ASME code editions were reviewed and compared; including some that were not addressed in the Reedy report. Significant code changes were reviewed to determine if they would have a major impact on the design basis, such that the code change could require a design change.

Potential major impacts were then reviewed against the current design practices, associated with the Pickering A project design modification packages. The conclusion was that all identified potential major impacts would have a minimal affect on the current design. As a result, modifications to systems and components, which were designed to ASME Boiler and Pressure Vessel Code Section III 1995 edition, Section VIII 1992 edition, and B31.1 1992 edition, are considered equivalent to those designed to the latest code editions.

Based on the above, Pickering Units 1,4 were demonstrated to meet the intent of the 1992 edition of B31.1 as part of Pickering A Return to Service. The conclusions drawn in NA44-CORR-00531-00190 [B.19-8] reflected the then current design of Pickering Units 1,4 against the 1992 edition of B31.1, and those conclusions are not impacted by Pickering NGS operation past 2020. Pickering NGS compliance against the latest version, B31.1-14, is addressed below.

As previously discussed, OPG Report N-REP-01903.1-10000 R017 [B.19-6] identifies all the significant changes in ASME B31.1 up to and including the 2014 edition. OPG has established the CNSC accepted process of using N-REP-01903.1-10000 R017 to demonstrate compliance with ASME pressure boundary codes. As discussed under Section B.19.2.2 below, the ECC process ensures that significant technical changes to B31.1 will be applied, as appropriate, for modifications going forward in accordance with OPG governance. Application of B31.1-14 to the as-built design is also discussed under Section B.19.2.2. The conclusion is that there are no PSR2 gaps for Pickering Units 1,4 compliance with ASME B31.1-14.

Darlington NGS

OPG Reports NK38-REP-03680-10026 R000, "Review of ASME B31.1 (December 2007), Power Piping for Darlington Integrated Safety Review" [B.19-9] and NK38-REP-03680-10134 R000, "Code Refresh Review of ASME B31.1-2012, Power Piping, for DNGS ISR" [B.19-10] document clause-by-clause reviews against the 2012 and 2007 editions of ASME B31.1. NK38-REP-03680-10026 R000 [B.19-9] stated that: "The B31.1 code structure and requirements did not undergo substantial alterations from the time of the construction license award to the Darlington station [1981], however, some of the technical requirements listed therein were subject to refinements and changes."

Given the ASME Code Reconciliation process discussed earlier (which is discussed further in Section B.19.2.2 below), the above Darlington ISR reviews have not been assessed further for applicability to Pickering NGS.

B.19.2.2 Application of Post PSR1 Reviews

N-CORR-00590-0454242 R001, "Code-over-Code Review of B31.1 Power Piping - 2012 over 2010" [B.19-11] reviewed the 2012 version of B31.1 and concluded that there was "no impact on existing installations".

According to ASME [B.19-3], the key changes in the 2014 edition of B31.1 include:

1. *Now mandatory rules for nonmetallic piping and piping lined with nonmetals;*
2. *Cold-forming rules for creep strength enhanced ferritic steels have been incorporated into Chapter V Fabrication, Assembly, and Erection;*
3. *Chapter VII Operation and Maintenance revised to include requirements for:*
    a. *Documentation of dynamic events*
    b. *Piping and pipe-support maintenance programs and personnel requirements;*
4. *Preheat and post-weld heat treatment rules have been reformatted into tabular form for clarity.*

With respect to the changes to B31.1-14, OPG Report, N-REP-00590-00006 R000, "Code-over-Code Review Report: ASME B31.1 Paragraph 127 to 132.7 for the Year 2014" [B.19-12] performed a review of the welding aspects of the 2014 edition of B31.1 against the 2012 edition (paragraphs 127 to 132.7 in both versions), and stated:

> *OPG's existing WPS'* [Welding Procedure Specifications] *were found to be compliant with the new requirements of the 2014 edition of ASME B31.1. No requalification is required as a result of the findings of this Code-Over-Code review.*

OPG Report, N-REP-04800-10001 R006, "ASME Code Summary Report for Reconciliation of Welding Procedure Specifications" [B.19-13] records the changes in ASME Code requirements for B31.1-14 as they pertain to welding and brazing and which may affect compliance with welding and brazing procedure specifications.

OPG Report, N-REP-00590-00001 R000, "Code-over-Code Review Report: ASME Power Piping B31.1 for the Year 2014" [B.19-14] performed a review of B31.1-14 against the 2012 version (except for the welding aspects covered under OPG Report N-REP-00590-00006 R000 [B.19-12] discussed above) and identified the four significant changes below:

- Item 4 paragraph 105.3 - Non-Metallic Pipe: Rules for non-metallic pipe were in non-mandatory Appendix III in the 2012 version of B31.1. There are now mandatory rules to cover non-metallic pipe in B31.1-14.
- Item 11 paragraph 122.8.2(I) - Toxic Fluids (Gas or Liquid): New requirements were added for the vent lines of Toxic fluids (gases or liquids).

- Item 13 paragraph 124.1.2 - Lower Temperature Limits: There are new requirements for lower temperature limits in Chapter III, "Materials". The 2012 edition of B31.1 was less prescriptive, stating only "The designer shall give consideration to the possibility of brittle fracture at low service temperature."

- Item 22 Appendix D, Table D-1 – General note added on the validity of stress intensification and flexibility factor data: B31.1-14 is more restrictive than the 2012 edition since "the limit of $D_o/t_n \leq 100$ applies to all configurations, not just concentric reducers".

The mitigation instituted for each finding above was to include the changes in N-LIST-00590-00001 R002, "List of Significant Technical Changes from Code-over-Code Review" [B.19-15]. All modifications require review of this document as identified in N-FORM-10959 R016, "Design Scoping Checklist" [B.19-16], as per N-PROC-MP-0090 R014, "Modification Process" [B.19-17] (N-FORM-10959 R016 Section 2.19 requires that a review of N-LIST-00590-00001 R002 "shall be completed to determine if any code change improvement actions apply to the modification"). As a result, significant technical changes to B31.1 will be applied, as appropriate, for modifications to existing Pickering NGS power piping going forward in accordance with OPG governance. The ECC process, together with a yearly examination of any incremental (Code-over-Code) review requirements due to changes to B31.1 per OPG Guideline, N-GUID-00590-00002 R001, "Code over Code Review - Guideline" [B.19-18], ensure that that any applicable design changes made to Pickering NGS comply with the latest edition of B31.1.

As previously discussed, OPG Report N-REP-01903.1-10000 R017, "ASME Code Reconciliation for Material, Parts and Components" [B.19-6] identifies all the significant changes in ASME B31.1 up to and including the 2014 edition. N-REP-01903.1-10000 R017 is used as a reference at OPG when designing pressure boundary repairs, replacements and modifications. With respect to the retroactive application of B31.1 to the as-built design at Pickering NGS, N-REP-01903.1-10000 R017 states:

> *This report verifies that ASME Section III, Division 1, Section VIII, Division 1, B31.1, and B31.7 have not made any design changes that depend on corresponding changes to material, fabrication, examination, testing or quality assurance requirements that change the original design basis of any equipment. The significant design changes since 1955 are identified, and methodology and detailed examples are given for selecting provisions from later Editions and Addenda to these Codes.*

OPG Letter NK30-CORR-00531-06324 R000, "Pickering NGS-B - CNSC staff assessment of OPG's 2011 Continued Operations Plan (Action Item 2010-8-05 (2461)) and path forward" [B.19-19] discusses OPG Report N-REP-01903.1-10000 R017 in relation to Pickering B ISR gaps identified for other ASME codes (Boiler Pressure Vessel Code), and states: "Pickering B will continue to follow the practice of designing pressure boundary repairs/replacements to code of construction and referencing the Reedy Report to ensure compliance to current standards. Inspection and testing practices continue to comply with N285.4-05 and 285.5-M90, per our PROL [Power Reactor Operating Licence]." The CNSC considered this response to be satisfactory [B.19-19].

With respect to OPG staff use of N-REP-01903.1-10000 R017 [B.19-6], OPG Memorandum N-CORR-01903.1-0381196, "Information on Reedy ASME Code Reconciliation Report and on Rapid

Access (RA) Database" [B.19-20] provides "basic information on what is contained in the ASME Code Reconciliation Report and in the Rapid Access (RA) database prepared by Reedy Engineering and how to access it. This information will help to support individuals who are required to use the earlier editions of ASME codes or sections thereof as a part of their job function and are especially useful for staff involved in performing reconciliations of different code editions." Further, OPG Guideline N-GUID-01913.11-10000 R002, "ASME Code Effective Date Reconciliation Guidelines" [B.19-21] provides information assisting OPG Design Engineers in: a) applying the code reconciliation process in accordance with OPG Instruction N-INS-01913.11-10020 R003, "Preparation of ASME Code Reconciliation for Pressure Boundary Items" [B.19-22]; b) determining the Required Code Effective Date of the design, and defining the item Code Effective Date; c) performing formal reconciliation on N-FORM-10911 R002, "Item Code Effective Date Reconciliation" [B.19-23] associated with the instruction N-INS-01913.11-10020 R003; and d) recognition of pre-reconciled items, which may be accepted without performing case-by-case reconciliation.

Based on the above, Pickering NGS meets the intent of ASME B31.1-14 since: a) OPG has established the CNSC accepted ASME Code Reconciliation process of using the Reedy Report to ensure ongoing compliance with B31.1, and, in parallel, b) there is a yearly examination of any incremental (Code-over-Code) review requirements which ensure that significant technical changes to B31.1 will be applied, as appropriate, for modifications to existing Pickering NGS power piping going forward.

B.19.3 Compliance Summary for Pickering PSR2

There are no PSR2 gaps for ASME B31.1-14 [B.19-1]. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with ASME B31.1-14.

B.20 ASME BPVC (2015), "Boiler and Pressure Vessel Code"

B.20.1 Background

The following excerpts paraphrased from ASME BPVC 2015 [B.20-1] provide a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of ASME BPVC is to regulate the design and construction of boilers and pressure vessels. The standard defines the requirements for the construction, inspection, and materials of boilers, pressure vessels, and nuclear components. It also provides guidance for the care and operation of boilers.*
>
> *The standard has been broken up into the following 12 sections:*
>
> - *Section I – Rules for Construction of Power Boilers*
> - *Section II – Materials*
> - *Section III – Rules for Construction of Nuclear Facility Components*
> - *Section IV – Rules for Construction of Heating Boilers*
> - *Section V – Non-Destructive Examination [NDE]*
> - *Section VI – Recommended Rules for the Care and Operation of Heating Boilers*
> - *Section VII – Recommended Guidelines for the Care of Power Boilers*
> - *Section VIII – Rules for Construction of Pressure Vessels*
> - *Section IX – Welding, Brazing and Fusing Qualifications*
> - *Section X – Fiber-Reinforced Plastic Pressure Vessels*
> - *Section XI – Rules for In-service Inspection of Nuclear Power Plant Components*
> - *Section XII – Rules for Construction and Continued Service of Transport Tanks*

BPVC Sections III and VIII are addressed by Pickering PSR2. Although power/heating boilers are applicable to Pickering NGS, they are not safety related and therefore Sections I, IV and VII do not apply to PSR2. Section II is a "Service Section" to the other BPVC Sections, providing material specifications for ferrous materials and requirements for chemical and mechanical properties, heat treatment and manufacture; therefore, Section II is only relevant to the manufacturing of components. Sections VI, X and XII do not apply to Pickering NGS. Sections

V, IX and XI were not assessed as part of PSR1 for either Darlington or Pickering NGS. Similar to the PSR1 assessment of ASME BPVC, only Sections III and VIII are addressed by PSR2.[17]

ASME BPVC is relevant to Safety Factor 1 (Plant Design).

ASME BPVC is identified in Appendix E.1 of the R04 Pickering Licence Conditions Handbook [B.20-5] as "Guidance or Criteria". However, ASME BPVC Section III is an indirect licence requirement, since compliance with CSA N285.0 (which calls up BPVC Section III) is a licence requirement as indicated in Appendix C.1 of the Licence Conditions Handbook [B.20-5].

ASME BPVC 2015 [B.20-1] supersedes numerous previous editions of the BPVC, most recently issued in 2013, 2010 and 2007. The origins of ASME BPVC date back to the early 1900's, with the first official edition published in 1914.

As discussed in Section B.20.2 below, OPG has established the CNSC accepted process of using the Reedy Engineering ASME Code Reconciliation Report to ensure ongoing compliance with BPVC Sections III and VIII, and, in parallel, there is a yearly examination of any incremental (Code-over-Code) review requirements which ensures that significant technical changes to BPVC will be applied, as appropriate, for modifications to existing Pickering NGS pressure vessels going forward.

The results of PSR1 ASME BPVC reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.20.2. As identified in Reference [B.20-6], the Pickering PSR2 review of ASME BPVC (2015) is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.

---

[17] For BPVC Section V, NDE required for the periodic inspection of nuclear components is performed in accordance with N-STD-MA-0021 R001, "Non-Destructive Examination" [B.20-2] to ensure that examinations performed meet code and regulatory requirements (periodic inspection is performed as a licensing requirement in compliance with CSA N285.4, N285.5 and N287.7). Additional ASME Section V specific examinations are applied by the pressure boundary program (e.g., I-IP-04163-XXXXX series of inspection and maintenance procedures). Welding, brazing and fusing (BPVC Section IX) is addressed via N-PROG-MA-0013 R009, "Welding" [B.20-3] which establishes controlled processes and standardized welding practices to make sound welds that meet safety, structural integrity, code, and licensing requirements, as stipulated in CSA N285.0. Section XI is addressed by periodic inspection of pressure-retaining components and their supports which is performed in accordance with CSA N285.4, per OPG Program N-PROG-MA-0017 R008, "Component and Equipment Surveillance" [B.20-4]. In addition, a yearly examination of any incremental (Code-over-Code) requirements due to changes to ASME BPVC Sections V and IX is undertaken by OPG, per OPG Guideline N-GUID-00590-00002 R001, "Code-over-Code Review – Guideline" [B.20-32].

- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.20.2 Compliance Assessment for Pickering PSR2

B.20.2.1 Application of PSR1 Reviews

The versions of the ASME BPVC (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

OPG Report NK30-REP-03680-00001 R000, "Pickering NGS-B Integrated Safety Review - Plant Design Safety Factor" [B.20-7] performed a clause-by-clause review of the 2001 edition of ASME BPVC Section III, up to and including the 2003 Addenda, and stated:

> *The majority of the gaps identified in the course of the review of Plant Design Safety Factor are associated with Section III of the ASME B&PV Code. Since the design and commissioning of the Pickering NGS-B, the ASME B&PVC Section III has evolved with a number of addenda and revisions which have resulted in some design criteria becoming more restrictive. A preliminary review has revealed that none of the gaps identified during the review poses a risk to operating plant and it is expected that these gaps will be successfully resolved following detailed review of the ASME B&PVC requirements. Accordingly, the Pickering B design is deemed to be in an Acceptable Deviation compliance with the ASME B&PVC Section III.*

OPG Letter NK30-CORR-00531-04739 R000, "Pickering NGS-B Integrated Safety Review - Discrepancy Resolution" [B.20-8] proposed the following disposition to the CNSC regarding Issue 1-359 (which amalgamated 134 Discrepancies):

> *ASME Section III - Significant Changes to Design Requirements, NX-2000 Revisions That May Affect Use of Earlier Materials: Perform case-by-case evaluations of ASME Boiler & Pressure Vessel Code Section III code changes, identify and disposition gaps in accordance with accepted OPG gap disposition process.*

The CNSC accepted the categorization of Issue 1-359 as a Discrepancy in CNSC Letter NK30-CORR-00531-04876 R000, "Pickering NGS-B - Integrated Safety Review (ISR) - CNSC Review of Acceptable Deviations and Discrepancies for the Plant Design Safety Factor Report" [B.20-9]. CNSC Letter NK30-CORR-00531-05008 R000, "Pickering NGS-B Discrepancy Resolution for Ageing, Safety Analysis, Emergency Planning, Environment, Plant Design and Management Safety Areas" [B.20-10] and OPG Report NK30-REP-03680-00016 R000, "OPG Response to CNSC Comments on Pickering NGS-B Integrated Safety Review - Plant Design, Safety Analysis, Safety Performance, Ageing and Equipment Qualification Safety Factors and Discrepancy

Resolutions" [B.20-11] acknowledged CNSC agreement with the planned Issue 1-359 disposition process.

Issue 1-359 was later closed in OPG Letter NK30-CORR-00531-06324 R000, "Pickering NGS-B - CNSC staff assessment of OPG's 2011 Continued Operations Plan (Action Item 2010-8-05 (2461)) and path forward" [B.20-12] on the basis that "OPG has established the process of using the Reedy Report to ensure compliance with ASME B&PVC Section III". OPG Report N-REP-01903.1-10000 R017, "ASME Code Reconciliation for Material, Parts and Components" [B.20-13], known as the Reedy Report, identifies all the significant changes in BPVC Sections III and VIII up to and including the 2015 edition. N-REP-01903.1-10000 R017 is used as a reference by OPG when designing pressure boundary repairs, replacements and modifications. NK30-CORR-00531-06324 R000 addressed N-REP-01903.1-10000 in relation to the Pickering B ISR BPVC Section III gaps, and stated:

> *The OPG practice for designing pressure boundary repairs/replacements, is to design to code of construction. All modifications are designed in compliance to ASME B&PVC Section III 2007, per our licence and per N-PROC-MP-0082-R06 "Design Registration"…*
>
> *Pickering B will continue to follow the practice of designing pressure boundary repairs/replacements to code of construction and referencing the Reedy Report to ensure compliance to current standards. Inspection and testing practices continue to comply with N285.4-05 and 285.5-M90, per our PROL [Power Reactor Operating Licence].*

CNSC staff agreed with the resolution, and stated that they considered the response to be satisfactory [B.20-12]. This is also applicable to BPVC Section VIII, since N-REP-01903.1-10000 R017 [B.20-13] addresses compliance with both BPVC 2015 Sections III and VIII. As discussed under Section B.20.2.2 below, the Engineering Change Control (ECC) process ensures that significant technical changes to ASME BPVC 2015 will be applied, as appropriate, for modifications going forward in accordance with OPG governance. Pickering NGS compliance against ASME BPVC 2015 edition, including application to the as-built design, is discussed further under Section B.20.2.2. The conclusion is that there are no PSR2 gaps for Pickering Units 5-8 compliance with Sections III and VIII of ASME BPVC 2015.

<u>Pickering Units 1,4</u>

OPG Report NA44-REP-00584.1-10001 R000, "Pickering A ASME Codes Reconciliation - Pickering A Return to Service" [B.20-14] was prepared to:

> *Summarize the study for an evaluation of the ASME Code Changes for the Pickering A Return to Service Project from the ASME VIII 1992 and ASME III 1995 Edition to the 1999 Addenda … and their impact on the design basis as per the CSA N285.0-95 requirements.*

The ASME Codes Reconciliation found no major impacts from the review against ASME Section III 1995 edition and ASME Section VIII 1992 edition (including the 1999 Addenda). OPG Letter NA44-CORR-00531-00190 R000, "ASME Codes Reconciliation - System and Component Modifications (Pickering NGS-A, Units 1-4)" [B.20-15] states:

For modifications, including associated equipment and material, CNSC indicated their acceptance of a case-by-case, code specific, reconciliation. In response, OPG has developed a master ASME codes reconciliation report, which addresses all code changes that impact Pickering A systems' design, equipment, and material. This codes reconciliation report (i.e., OPG Report No. NA44-REP-00584.1-10001, Rev. 00, 30 August 2000), entitled "Pickering A ASME Codes Reconciliation," is enclosed for your information and use….

The code reconciliation report was based primarily on a technical report, prepared by Reedy Engineering, entitled "ANSI/ASME Code Reconciliation for Replacement Material, Parts, and Components," Rev. 9, 7 January 2000. In addition, various ASME code editions were reviewed and compared; including some that were not addressed in the Reedy report. Significant code changes were reviewed to determine if they would have a major impact on the design basis, such that the code change could require a design change.

Potential major impacts were then reviewed against the current design practices, associated with the Pickering A project design modification packages. The conclusion was that all identified potential major impacts would have a minimal effect on the current design. As a result, modifications to systems and components, which were designed to ASME Boiler and Pressure Vessel Code Section III 1995 edition, Section VIII 1992 edition, and B31.1 1992 edition, are considered equivalent to those designed to the latest code editions.

Based on the above, Pickering Units 1,4 compliance with ASME Section III 1995 edition and ASME VIII 1992 edition was demonstrated as part of Pickering A Return to Service. These conclusions are not impacted by Pickering NGS operation past 2020.

As discussed previously, OPG Report N-REP-01903.1-10000 R017 [B.20-13] identifies all the significant changes in BPVC Sections III and VIII up to and including the 2015 edition. OPG has established the process of using N-REP-01903.1-10000 R017 to demonstrate compliance with ASME BPVC, and this process has been accepted by the CNSC. As discussed under Section B.20.2.2 below, the ECC process ensures that significant technical changes to ASME BPVC 2015 will be applied, as appropriate, for modifications going forward in accordance with OPG governance. Pickering NGS compliance against ASME BPVC 2015 edition, including application to the as-built design, is discussed further under Section B.20.2.2. The conclusion is that there are no PSR2 gaps for Pickering Units 1,4 compliance with Sections III and VIII of ASME BPVC 2015.

Darlington NGS

OPG Reports NK38-REP-03680-10028 R000, "Review of ASME BPVC Section VIII Design and Fabrication of Pressure Vessels for Darlington ISR" [B.20-16] and NK38-REP-03680-10133 R000, "Code Refresh Review of ASME Boiler and Pressure Vessel Code, Section VIII (July 2007 to July 2013) Rules for Construction of Pressure Vessels" [B.20-17] addressed Darlington NGS compliance with the 2007 and 2013 editions of BPVC Section VIII, respectively. OPG Reports NK38-REP-03680-10027 R000, "Review of ASME BPVC Section III Rules for Construction of NPP Components for Darlington ISR" [B.20-18] and NK38-REP-03680-10132 R000, "Code Refresh Review of ASME Boiler and Pressure Vessel Code, Section III (July 2007 to July 2013) Rules for

Construction of Nuclear Facility Components" [B.20-19] addressed compliance for the 2007 and 2013 editions of BPVC Section III. OPG Reports NK38-REP-03680-10027 ADD-001 R000, "Addendum to the ASME Boiler and Pressure Vessel Section III Code Review Report for Darlington ISR" [B.20-20] and NK38-REP-03680-10028 ADD-001 R000, "Addendum to the ASME Boiler Sec VIII Code Review Report for Darlington ISR" [B.20-21] document CNSC staff comments and OPG responses related to the ASME BPVC Section VIII and III findings.

Given the ASME Code Reconciliation process discussed previously (which is discussed further in Section B.20.2.2 below), the above Darlington ISR reviews have not been assessed further for applicability to Pickering NGS.

B.20.2.2 Application of Post PSR1 Reviews

With respect to the changes to the 2015 edition of BPVC Sections III and VIII, the following Code-over-Code reviews were recently performed by OPG:

- OPG Report, N-REP-00590-0557392 R001, "Code-over-Code Review Report: ASME Section III NCA for the Year 2015" [B.20-22];
- OPG Report, N-REP-00590-00009 R001, "Code-over-Code Review Report: ASME III/1 Subsection NB- 2013 Edition Over 2015 Edition for the Year 2015" [B.20-23];
- OPG Report, N-REP-00590-00010 R001, "Code-over-Code Review Report: ASME III/1 Subsection NC- 2013 Edition Over 2015 Edition for the Year 2015" [B.20-24]
- OPG Report, N-REP-00590-00011 R001, "Code-over-Code Review Report: ASME III/1 Subsection ND- 2013 Edition Over 2015 Edition for the Year 2015" [B.20-25];
- OPG Report, N-REP-00590-00012 R000, "Code-over-Code Review Report: ASME III/1 Subsection NE- 2013 Edition Over 2015 Edition for the Year 2015" [B.20-26];
- OPG Report, N-REP-00590-00013 R001, "Code-over-Code Review Report: ASME III/1 Subsection NF- 2013 Edition Over 2015 Edition for the Year 2015" [B.20-27]; and
- OPG Report, N-REP-00590-0564946 R002, "Code-over-Code Review Report: ASME VIII/1-2015 Edition - ASME VIII/1-2013 Edition UG-125 to UG-140 Overpressure Protection for the Year 2015" [B.20-28].

A number of significant changes were identified. The mitigation instituted for each finding is to include the changes in N-LIST-00590-00001 R002, "List of Significant Technical Changes from Code-over-Code Review" [B.20-29]. All modifications require review of this document as identified in N-FORM-10959 R016, "Design Scoping Checklist" [B.20-30], as per N-PROC-MP-0090 R014, "Modification Process" [B.20-31] (N-FORM-10959 R016 Section 2.19 requires that a review of N-LIST-00590-00001 R002 "shall be completed to determine if any code change improvement actions apply to the modification"). As a result, significant technical changes to the 2015 edition of ASME BPVC Sections III and VIII will be applied, as appropriate, for modifications to existing Pickering NGS pressure vessels going forward in accordance with OPG governance. The ECC process, together with a yearly examination of any incremental (Code-over-Code) review requirements due to changes to ASME BPVC per OPG Guideline, N-GUID-

00590-00002 R001, "Code-over-Code Review - Guideline" [B.20-32], ensure that that any applicable design changes made to Pickering NGS comply with the latest edition of the BPVC.

As discussed previously, OPG Report N-REP-01903.1-10000 R017 [B.20-13] identifies all the significant changes in BPVC Sections III and VIII up to and including the 2015 edition. N-REP-01903.1-10000 R017 is used as a reference at OPG when designing pressure boundary repairs, replacements and modifications. With respect to the retroactive application of BPVC Sections III and VIII to the as-built design at Pickering NGS, N-REP-01903.1-10000 R017 states:

> *This report verifies that ASME Section III, Division 1, Section VIII, Division 1, B31.1, and B31.7 have not made any design changes that depend on corresponding changes to material, fabrication, examination, testing or quality assurance requirements that change the original design basis of any equipment. The significant design changes since 1955 are identified, and methodology and detailed examples are given for selecting provisions from later Editions and Addenda to these Codes.*

As discussed previously, OPG Letter NK30-CORR-00531-06324 R000, "Pickering NGS-B - CNSC staff assessment of OPG's 2011 Continued Operations Plan (Action Item 2010-8-05 (2461)) and path forward" [B.20-12] identifies that "OPG has established the process of using the Reedy Report to ensure compliance with ASME B&PVC Section III". CNSC staff agreed with OPG, and stated that they considered this response to be satisfactory [B.20-12]. This is also applicable to ASME BPVC Section VIII, since N-REP-01903.1-10000 R017 [B.20-13] addresses changes to both Sections III and VIII.

With respect to OPG staff use of N-REP-01903.1-10000 R017 [B.20-13], OPG Memorandum N-CORR-01903.1-0381196, "Information on Reedy ASME Code Reconciliation Report and on Rapid Access (RA) Database" [B.20-33] provides "basic information on what is contained in the ASME Code Reconciliation Report and in the Rapid Access (RA) database prepared by Reedy Engineering and how to access it. This information will help to support individuals who are required to use the earlier editions of ASME codes or sections thereof as a part of their job function and are especially useful for staff involved in performing reconciliations of different code editions." Further, OPG Guideline N-GUID-01913.11-10000 R002, "ASME Code Effective Date Reconciliation Guidelines" [B.20-34] provides information assisting OPG Design Engineers in: a) applying the code reconciliation process in accordance with OPG Instruction N-INS-01913.11-10020 R003, "Preparation of ASME Code Reconciliation for Pressure Boundary Items" [B.20-35]; b) determining the Required Code Effective Date of the design, and defining the item Code Effective Date; c) performing formal reconciliation on N-FORM-10911 R002, "Item Code Effective Date Reconciliation" [B.20-36] associated with the instruction N-INS-01913.11-10020; and d) recognition of pre-reconciled items, which may be accepted without performing case-by-case reconciliation.

Based on the above, Pickering NGS meets the intent of ASME BPVC 2015 Sections III and VIII since: a) OPG has established the CNSC accepted ASME Code Reconciliation process of using the Reedy Report to ensure ongoing compliance with BPVC Sections III and VIII, and, in parallel, b) there is a yearly examination of any incremental (Code-over-Code) review requirements which ensures that significant technical changes to BPVC will be applied, as appropriate, for modifications to existing Pickering NGS pressure vessels going forward.

B.20.3 Compliance Summary for Pickering PSR2

There are no PSR2 gaps for ASME BPVC (2015) [B.20-1]. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with ASME BPVC (2015).

B.21 CSA B51-14, "Boiler, Pressure Vessel, and Pressure Piping Code"

B.21.1 Background

The following excerpt paraphrased from the Preface of CSA B51-14 (including Update No. 1) [B.21-1] provides a brief overview of the purpose of the standard and the requirements expressed therein:

> *The purpose of CSA B51 is to promote safe design, construction, installation, operation, inspection, testing, and repair practices. The requirements defined within the standard are split into three parts:*
>
> - *Part 1 contains the requirement for boilers, pressure vessels, pressure piping, and fittings.*
> - *Part 2 contains the requirements for high-pressure cylinders for the on-board storage of natural gas, blends of natural gas and hydrogen (hydrogen blends), and hydrogen as fuels for automotive vehicles.*
> - *Part 3 contains requirements for compressed natural gas and hydrogen refuelling station pressure piping systems and ground storage vessels.*

CSA B51 Parts 2 and 3 are not relevant to Pickering NGS and not addressed in PSR2. As discussed in the PSR2 Basis Document [B.21-2], the scope of the Structures, Systems and Components (SSCs) within the PSR2 review encompasses Pickering NGS safety related systems, with a focus on Systems Important to Safety (SIS) and Safe Operating Envelope (SOE) Systems.

CSA B51 is relevant to Safety Factor 1 (Plant Design).

CSA B51 is identified in Appendix E.1 of the R04 Pickering Licence Conditions Handbook [B.21-3] as "Guidance or Criteria". However, B51 is an indirect licence requirement, since compliance with CSA N285.0, "General Requirements for Pressure Retaining Systems and Components in CANDU Nuclear Plants" (which calls up B51) is a licence requirement as indicated in Appendix C.1 of the Licence Conditions Handbook [B.21-3].

CSA B51-14 is the eighteenth edition of this standard, and supersedes numerous previous editions of B51, most recently issued in 2009, 2003 and 1995. The Preface to CSA B51-14 (including Update No. 1) [B.21-1] identifies the significant technical changes to the standard, which are discussed in Section B.21.2.2.

The results of PSR1 CSA B51 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.21.2. As identified in Reference [B.21-2], the Pickering PSR2 review of CSA B51-14 (including Update No. 1) [B.21-1] is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.

- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.21.2 Compliance Assessment for Pickering PSR2

B.21.2.1 Application of PSR1 Reviews

The versions of CSA B51 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

OPG Report NK30-REP-03680-00001 R000, "Pickering NGS-B Integrated Safety Review - Plant Design Safety Factor" [B.21-4] documents a clause-by-clause review of CSA B51-03 [B.21-5] Part 1 against SOE/SIS systems, and found:

> *The compliance assessment covers Part 1 of the B51 standard which has been specified for pressure retaining components. The review set out to identify gaps in the design of the SOE/SIS systems due to revisions in the B51-1975 standard, which applied during the design and construction of Pickering B, compared to B51-03, which is the most recent revision of the standard. The clause-by-clause review found no gaps in requirements that would require a design change to be made to the existing Pickering B SOE/SIS systems to satisfy B51-03.*
>
> *No additional action is required to establish compliance with the Standard B51-03 of the Pickering 'B' SOE/SIS systems after refurbishment has been completed.*

NK30-REP-03680-00001 R000 [B.21-4] classified the following three CSA B51-03 [B.21-5] clauses as Acceptable Deviations, and the rest of the clauses as compliant or not applicable/relevant:

- Clause 4.2.1, which relates to registry of fittings intended for use on boilers, pressure vessels and piping;

- Clause 7.5.1.3, which relates to requirements on minimum diameter and volume of the blow off vessel for a coil-tube boiler having a capacity of less than 1200 litres; and

- Clause 7.5.2.1, which specifies access opening requirements to facilitate internal inspection and permit cleaning.

At the CNSC's request, Clause 4.2.1 was reclassified as a Discrepancy as documented in OPG Report NK30-REP-03680-00015 R000, "Pickering NGS-B Integrated Safety Review (ISR) - Final ISR Report" [B.21-6]. The remaining two Acceptable Deviations were addressed in NK30-REP-

03680-00015 R000 [B.21-6], with no further action required. The CNSC accepted reclassification of Clause 4.2.1 as an Acceptable Deviation in CNSC Letter NK30-CORR-00531-05312 R000, "Pickering NGS-B Integrated Safety Review (ISR) - CNSC Staff Response to OPG's Comment Disposition Report" [B.21-7], which states:

> *OPG continues to believe that this item should be categorized as Acceptable Deviation and provides the following additional supporting justification. Clause 4.2.1 in B51-03 applies to the manufacturer of fittings, and thus has no impact on current installed fittings in the plant systems. Registration every 10 years is a requirement of the manufacturer to ensure that their QA meets requirements and that they have a valid certificate of authorization for the fabrication of these fittings. This enables OPG to ensure that applicable new fittings coming into the plant comply with the code clause.*

Per OPG Letter NK30-CORR-00531-05578, "Pickering NGS-B - Follow-up to the Closure of the Integrated Safety Review (ISR) Study" [B.21-8], there were no unaddressed findings relating to CSA B51-03 compliance upon closure of the Pickering B ISR project. None of the Acceptable Deviations identified above are impacted by Pickering NGS operation beyond 2020. In addition, the findings and dispositions are generally applicable to Pickering Units 1,4, given the similarities in inspection, testing and registration requirements, as well as design and material specifications, between the units for boilers, pressure vessels, pressure piping, and fittings.

Based on the above, there are no PSR2 gaps associated with previous Pickering B ISR reviews against CSA B51-03 [B.21-5]. Pickering NGS compliance with subsequent editions of CSA B51 is addressed below.

<u>Pickering Units 1,4</u>

With respect to review against CSA B51 as part of Pickering A Return to Service, subsection VII.1.3, "Codes and Standards for Return to Service" of OPG Letter NA44-CORR-00531-00381 R000, "Pickering A - Updated Basis for Return to Service Document" [B.21-9], made the following statement:

> *For modifications, CSA N285.0-95 and CSA B51-95 shall be followed with specific conditions as specified in the AECB's approval letter.*

Part 6, "Evaluation of Code Class Requirements Against CSA Standards N285.0 and N285.2" of AECL Assessment Document 44RS-00531-ASD-001 Rev. 04, "Review of Pickering A Design Against Current Codes and Standards" [B.21-10] noted that:

> *The requirement to comply with the CSA N285.0-95 is stated in the Pickering 'A' Power Reactor Operating License (PROL). The PROL, in part, requires OPG to "design, modify, repair, test, inspect and otherwise perform work on vessels, systems, piping, fittings, components and supports according to the technical requirements of CSA Standard N285.0-95 (and B51-95)."*

Alignment with CSA B51-95 [B.21-11] was further addressed in OPG Letter NA44-CORR-00531-00190 R000, "ASME Codes Reconciliation - System and Component Modifications (Pickering NGS-A, Units 1-4)" [B.21-12], which stated:

For modifications, including associated equipment and material, CNSC indicated their acceptance of a case-by-case, code specific, reconciliation. In response, OPG has developed a master ASME codes reconciliation report, which addresses all code changes that impact Pickering A systems' design, equipment, and material. This codes reconciliation report (i.e., OPG Report No. NA44-REP-00584.1-10001, Rev. 00, 30 August 2000), entitled "Pickering A ASME Codes Reconciliation", is enclosed…

The codes reconciliation report reflects the overall results of our evaluation, and shows that the Pickering A systems and components will, in general, satisfy the requirements of CSA N285.0-95 and B51-95.

Section 5.6 of the Pickering PROL Renewal Application [B.21-13], which was prepared in 2012, confirms alignment at the time with CSA B51-03 [B.21-5]:

The N-MAN-01913.11-10000, Pressure Boundary Program Manual [B.21-14]*, describes the program used to control the quality of pressure boundary activities at OPG Nuclear facilities and stations. It complies with CSA N285.0, General Requirements for Pressure Retaining Systems and Components in CANDU Nuclear Power Plants, and CSA B51, Boiler, Pressure Vessel, and Pressure Piping Code. Pressure boundary requirements for all states of work, from design through to installation and testing, are implemented through OPG Nuclear governing documents.*

Pickering has implemented CSA N285.0-2008 Update 1 and B51-03 for pressure boundary activities at site in 2010. The OPG QA Manual, along with associated Standards and Procedures, were revised to comply with 2008 Edition of N285.0 with Update 1 and 2003 edition of B51.

After a successful survey by the Technical Standards & Safety Authority (TSSA) demonstrating pressure boundary processes to be in compliance with the Pressure Boundary Program Manual, Certificates of Authorization (C of A) for Pressure Boundary activities were renewed for another three years…

Section 2.1 of OPG Manual N-MAN-01913.11-10000 R016, "Pressure Boundary Program Manual" [B.21-14], which was most recently updated in 2015, states:

This Pressure Boundary (PB) Program Manual (hereinafter referred to as the Manual) complies with the applicable rules and quality requirements contained in the Canadian Standards Association (CSA) N285.0 and CSA B51 standards for Class 1, 1C, 2, 2C, 3, 3C, 4, and 6 systems and items, as applicable. The Code Effective Date for activities initiated after October 30, 2013 has been established under the terms of the PROLs and WFOLs [Waste Facility Operating Licence] as follows: - CSA N285.0-08 with Update 1, Update 2, Annex K, Annex M - CSA B51-09 with Update 1…

Based on the above, OPG Governance, which is applicable across OPG's nuclear fleet, currently requires compliance with CSA B51-09 (including Update No. 1) [B.21-15]. As a result, there are no PSR2 gaps for Pickering Units 1,4 or Units 5-8 compliance with CSA B51-09 (including Update No. 1). Pickering NGS compliance with subsequent editions of CSA B51 is addressed below.

Darlington NGS

OPG Report NK38-REP-03680-10029 R000, "Review of CAN/CSA-B51-03 (R2007) (March 2003), Boiler, Pressure Vessel, and Pressure Piping Code for Darlington Integrated Safety Review" [B.21-16] performed a clause-by-clause review against CSA B51-03 [B.21-5] Part 1, and concluded:

> *The CAN/CSA B51-03 conformity assessment of nine Darlington NGS pressure-retaining systems was found to show full compliance with the Standard.*

OPG Report NK38-REP-03680-10029-ADD-001 R000, "Addendum to the CAN/CSA-B51-03 Code Review Report for Darlington ISR" [B.21-17] documents CNSC staff comments and OPG responses related to OPG Report NK38-REP-03680-10029 R000 [B.21-16]. OPG responses to CNSC comments 024/025/026 were deemed acceptable, with no further action required.

OPG Report NK38-REP-03680-10104-ADD-001 R000, "Darlington NGS ISR - Final ISR Report Addendum" [B.21-18] noted six gaps against CSA B51-09, which were grouped into three ISR Issues (D483/D488/D489) and classified as Acceptable Deviations. These Acceptable Deviations were related to long-standing Darlington NGS concessions against B51. OPG Report NK38-REP-03680-10201 R001, "ISR Open Issues and Acceptable Deviations – Adequacy Review" [B.21-19] discussed Issues D483 and D488, which are both labelled 'CSA B51-09 Hydrostatic Test Concession', and Issue D489 which is labelled 'CSA B51-09 Defective Pipe Concession'. The concessions were classified as Acceptable Deviations and ranked as having very low safety significance. All three of the associated concessions were specific to Darlington and thus are not applicable to Pickering PSR2. (Note: Per the PSR2 Basis Document [B.21-2], PSR2 Safety Factor Reports include a separate review of the Pickering Licence Conditions Handbook [B.21-3] for any impacts of Pickering NGS operation beyond 2020 on: a) OPG commitments previously made to the CNSC, and b) exemptions granted by the CNSC).

OPG Report NK38-REP-03680-10135 R000, "Code Refresh Review of CSA B51-09-UPD1, Boiler, Pressure Vessel, and Pressure Piping Code for Darlington ISR" [B.21-20] prepared a clause-by-clause review of CSA B51-09 (including Update No. 1) [B.21-15] versus CSA B51-03 [B.21-5], and concluded:

> *The changes made in CSA B51-09 UPD 1 relative to CSA B51-03 (R2007) included very minor changes, mostly for clarification purposes. The review of the changed clauses in this code refresh report confirms that OPG Nuclear governance continues to be compliant with the requirements of CSA B51-09 UPD 1.*

The Darlington ISR results therefore confirm that OPG Governance, which is applicable across OPG's nuclear fleet, is compliant with the requirements of CSA B51-09 (including Update No. 1) [B.21-15]. Pickering NGS compliance with the latest edition, CSA B51-14 (including Update No. 1) [B.21-1], is addressed in Section B.21.2.2 below.

B.21.2.2 Application of Post PSR1 Reviews

As discussed earlier, Pickering Units 1, 4 and 5-8 have demonstrated compliance against CSA B51-95 [B.21-11] and B51-03 [B.21-5], respectively, and the Units 5-8 B51-03 conclusions are generally applicable to Units 1,4 given the similarities in inspection, testing and registration requirements, as well as design and material specifications, as discussed in Section B.21.2.1. Similarly, although the three OPG plants (Darlington, Pickering Units 1,4 and Pickering Units 5-8) have differences in age, there are many similarities between the plants in terms of inspection, testing and registration requirements (as well as material specifications and design) of boilers, pressure vessels, pressure piping, and fittings. Therefore, the Darlington ISR review against CSA B51-09 (including Update No. 1) [B.21-15], which identified no safety significant findings, is also generally applicable to Pickering NGS. Furthermore, OPG Governance is compliant with the requirements of CSA B51-09 (including Update No. 1) [B.21-15] as discussed above.

The current edition of the standard is CSA B51-14 (including Update No. 1) [B.21-1], which supersedes CSA B51-09 (including Update No. 1) [B.21-15]. The Preface of CSA B51-14 (including Update No. 1) [B.21-1] provides the following information on the changes to this most recent version of the standard:

> *This Standard has undergone substantial technical and editorial revisions since the previous edition in 2009. Significant changes to Part 1 include the following:*
>
> *(a) The following definitions have been added to Clause 3:*
>
> *(i) air heater coil;*
>
> *(ii) historical steam boiler;*
>
> *(iii) owner;*
>
> *(iv) pressure relief device (PRD); and*
>
> *(v) thermal expansion relief valve.*
>
> *(b) General requirements: Clauses 4.1.1, 4.1.4, 4.2.4, 4.2.8, 4.6.5, 4.7.1, 4.7.2 Note 1, 4.8.2, 4.8.3, 4.9.3 Note, and 4.10 have been updated, and Clauses 4.1.9, 4.1.10, 4.2.5, and 4.2.6 have been added.*
>
> *(c) Boilers and related components: Clauses 6.2.1 and 6.7 have been updated, and Clauses 6.2.2 and 6.5.1 Note 3 have been added.*
>
> *(d) Pressure vessels — applicable codes and standards: Clauses 7.1.2 and 7.1.4 have been added.*
>
> *(e) Piping and fittings: Clause 8.1(c) has been updated.*
>
> *(f) Repairs and alterations: Clause 11.5 has been added.*
>
> *(g) Pressure relief devices: Clause 12 has been added.*
>
> *(h) In-service inspection: Clause 13 has been added.*

(i) *Categories of fittings: Table 1 Note 2 has been updated.*

(j) *Maximum servicing intervals: Table 5 has been added.*

(k) *The sample forms in Annex D have been updated to include cast aluminum.*

(l) *Requirements for a crush test for manifold vessels have been added to Annex G (Clause G.3.7).*

(m) *Provisions applicable to overpressure protection devices have been revised (Annex H).*

(n) *Requirements for historical boilers have been added (Annex I).*

(o) *Requirements regarding the use of finite elements analysis (FEA) to support a pressure equipment design submission have been added (Annex J).*

OPG Report N-REP-00590-0555896 R001, "Code-over-Code Review Report: CSA B51 for the Year 2015" [B.21-21] performed a Code-over-Code review of CSA B51-14 (including Update No. 1) [B.21-1] versus B51-14 [B.21-22], and stated:

There are no significant technical changes to CSA B51-14 Update 1.

OPG Report N-REP-00590-0520103 R000, "Code-over-Code Review Report: CSA B51 for the Year 2014" [B.21-23] performed a Code-over-Code review of CSA B51-14 [B.21-22] versus B51-09 (including Update No. 1) [B.21-15], and stated:

The following clauses have been identified as having significant technical changes and will be included in N-LIST-00590-00001, List of Significant Technical changes from Code-Over-Code Review.

Clause	***Description***
4.1.9	*New Clause. Requirements for Division 2 or 3 vessels regarding registration submissions, contents of design specifications, sale of vessels and change of ownership.* *Remarks & Mitigation Plans to Address Significant Changes - There are no Pressure Vessels constructed to ASME Section VIII Division 2 or 3 in OPG, however, this new requirement will be included in the revision to the N-LIST-00590-00001, List of Significant Technical Changes From Code-Over-Code Review.*
4.1.10	*New Clause. Addresses use of FEA [Finite Element Analysis] used to support design of pressure equipment.* *Remarks & Mitigation Plans to Address Significant Changes - This new requirement will be included in the revision to the N-LIST-059000001, List of Significant Technical Changes From Code-Over-Code Review.*
7.1.2	*New Clause. Mandates use of ASME Section VIII, Division 1, Appendix FF for [design of] pressure vessels incorporating quick-actuating closure.*

Clause	Description
	Remarks & Mitigation Plans to Address Significant Changes - This new requirement will be included in the revision to the N-LIST-0059000001, List of Significant Technical Changes From Code-Over-Code Review.
7.1.4	*New Clause. Addresses pressure vessels designed for cyclic service to ASME Section VIII, division 2 or 3.* *Remarks & Mitigation Plans to Address Significant Changes - There are no Pressure Vessels constructed to ASME Section VIII Division 2 or 3 in OPG, however, this new requirement will be included in the revision to the N-LIST-00590-00001, List of Significant Technical Changes From Code-Over-Code Review.*
12.2.1 (12.2.1.1 and 12.2.1.2)	*New clause. Addresses design of overpressure protection.* *Remarks & Mitigation Plans to Address Significant Changes - Not required. OPG over-pressure protection is in compliance with requirements of the licence and CSA N285.0 which envelopes the requirements of Clause 12.*
12.2.2 (12.2.2.1 through 12.2.2.10)	*New clause. Addresses installation of pressure relief devices.* *Remarks & Mitigation Plans to Address Significant Changes - Not required. OPG over-pressure protection is in compliance with requirements of the licence and CSA N285.0 which envelopes the requirements of Clause 12.*

The mitigation instituted for the CSA B51-14 [B.21-22] clauses identified above was to include significant technical changes in the next revision of N-LIST-00590-00001 R002, "List of Significant Technical Changes from Code-over-Code Review" [B.21-24]. All modifications require review of this document as identified in N-FORM-10959 R016, "Design Scoping Checklist" [B.21-25], as per N-PROC-MP-0090 R014, "Modification Process" [B.21-26] (N-FORM-10959 R016 Section 2.19 requires that a review of N-LIST-00590-00001 R002 "shall be completed to determine if any code change improvement actions apply to the modification"). In addition, there is a yearly examination of any incremental (Code-over-Code) review requirements which ensures that significant technical changes to B51 will be applied going forward, per OPG Guideline N-GUID-00590-00002 R001, "Code over Code Review - Guideline" [B.21-27]. As a result, significant technical changes will be applied, as appropriate, for future modifications to existing Pickering NGS installations in accordance with OPG governance. Further, compliance against the above-mentioned clauses is not required (or not applicable) to Pickering NGS, except for Clauses 4.1.10 and 7.1.2 which relate to design-support activities for pressure equipment/vessels as discussed below:

- Clause 4.1.10 of CSA B51-14 (including Update No. 1) [B.21-1] states: "Finite element analysis (FEA) may be used to support pressure equipment design where the configuration is not covered by the available rules in the code of construction…. Note: The designer should check with the regulatory authority to confirm that use of FEA is acceptable." Per Annex J of CSA B51-14, the intent of this clause is to identify potential compliance demonstration alternatives when pressure equipment design configurations are not covered by the available rules in the ASME code. In these situations, Annex J of B51-14 specifies the protocol to be followed. Clause 4.1.10 does not require that FEA be performed to prove a design; rather, it states what the requirements are if it is performed. Furthermore, although FEA was not available or utilized during initial design of Pickering NGS pressure piping and fittings, requisite safety margins were integrated into the design at the time to account for analytical uncertainties. As a result, Clause 4.1.10 does not impact the original design basis and is not safety significant.

- Clause 7.1.2 mandates the use of ASME Boiler Pressure Vessel Code (BPVC) Section VIII, Division 1, Appendix FF for the design of pressure vessels incorporating quick-actuating closure. As discussed in the separate PSR2 review of ASME BPVC, Pickering NGS meets the intent of BPVC Section VIII. OPG Report N-REP-01903.1-10000 R017, "ASME Code Reconciliation for Material, Parts and Components" [B.21-28], known as the Reedy Report, identifies all the significant changes in BPVC Sections III and VIII (including Division 1) up to and including the latest 2015 edition. As discussed in the PSR2 BPVC review, OPG Letter NK30-CORR-00531-06324 R000, "Pickering NGS-B - CNSC staff assessment of OPG's 2011 Continued Operations Plan (Action Item 2010-8-05 (2461)) and path forward" [B.21-29] states that "OPG has established the process of using the Reedy Report to ensure compliance with ASME B&PVC Section III" in response to CNSC questions on Pickering B ISR Issue 1-359 (which relates to resolution of significant changes to BPVC that may impact the original design basis of the plant). CNSC staff agreed with OPG, and stated that they considered the response in NK30-CORR-00531-06324 R000 [B.21-29] to be satisfactory. This is also applicable to ASME BPVC Section VIII, since N-REP-01903.1-10000 R017 [B.21-28] addresses changes to both Sections III and VIII. Pickering NGS meets the intent of ASME BPVC Section VIII and there is therefore no PSR2 gap associated with compliance with CSA B51 Clause 7.1.2.

Based on the above, application of CSA B51-14 (including Update No. 1) [B.21-1] results in no findings that need to be addressed for Pickering NGS, unless modifications are made in the future. The Engineering Change Control (ECC) process (which includes review of N-LIST-00590-00001 R002 [B.21-24]), together with a yearly examination of any incremental (Code-over-Code) review requirements due to changes to CSA B51 (per OPG Guideline N-GUID-00590-00002 R001 [B.21-27]), ensures that that any applicable design changes made to Pickering NGS comply with the latest version of B51 going forward. Therefore, there are no PSR2 gaps for Pickering NGS compliance with CSA B51-14 (including Update No. 1) [B.21-1].

B.21.3 Compliance Summary for Pickering PSR2

There are no PSR2 gaps for CSA B51-14 (including Update No. 1) [B.21-1]. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with CSA B51-14 (including Update No. 1).

B.22 NFPA 20 (2016), "Standard for the Installation of Stationary Pumps for Fire Protection"

B.22.1 Background

The following excerpts paraphrased from NFPA 20 (2016) [B.22-1] provide a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of NFPA 20 is to provide a reasonable degree of protection for life and property from fire through selection and installation requirements for stationary pumps for fire protection based upon sound engineering principles, test data, and field experience. NFPA 20 criteria address the full range of issues and apply to all types of pumps including those for high-rise buildings, centrifugal, vertical shaft turbine-type, and positive displacement.*
>
> *The standard deals with the selection and installation of pumps supplying liquid for private fire protection. The scope includes liquid supplies; suction, discharge, and auxiliary equipment; power supplies, including power supply arrangements; electric drive and control; diesel engine drive and control; steam turbine drive and control; and acceptance tests and operation.*

NFPA 20 is relevant to Safety Factor 1 (Plant Design).

Compliance with NFPA 20 is not a licence requirement for Pickering NGS (PROL 48.02/2018), although it is referred to in the R04 Pickering Licence Conditions Handbook [B.22-2]. It may be considered an indirect licence requirement as CSA N293-07, "Fire Protection for CANDU Nuclear Power Plants" [B.22-3] is a licence requirement and refers to NFPA 20 as follows:

> *5.1.3 Where specific design or operational requirements are not addressed in this Standard, the NBCC [National Building Code of Canada], or the NFCC [National Fire Code of Canada], good engineering practice shall apply and, where appropriate, recognized Standards (such as those of the National Fire Protection Association [NFPA]) shall be used.*
>
> *7.3.2.2 Fire pumps shall be provided in accordance with this Standard and NFPA 20.*

NFPA 20 (2016) is the twentieth edition of the standard, and supersedes the previous edition published in 2013. Other recent editions include changes in 2010 and 2007. The Preface of the current 2016 edition of NFPA 20 [B.22-1] provides information on recent changes which are discussed in Section B.22.2.2.

The results of PSR1 NFPA 20 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.22.2. As identified in Reference [B.22-4], the Pickering PSR2 review of NFPA 20 (2016) is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.

- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.22.2 Compliance Assessment for Pickering PSR2

B.22.2.1 Application of PSR1 Reviews

The versions of NFPA 20 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

No review was performed against NFPA 20 as part of the Pickering B ISR. OPG Report NK30-REP-03680-00001 R000, "Pickering NGS-B Integrated Safety Review - Plant Design Safety Factor" [B.22-5] discusses NFPA 20 in terms of other standards requiring general compliance with NFPA standards (e.g., CSA N293-07 [B.22-3] which states: "…where appropriate, recognized Standards (such as those of the National Fire Protection Association [NFPA]) shall be used"). Reviews against NFPA 20 were also not performed as part of the 2000 or 2010 Pickering B Fire Protection Code Compliance Review (CCR) assessments ([B.22-6], [B.22-7] respectively).

Although a review was not completed against NFPA 20 for the Pickering B ISR or CCRs, a review was not required since the fire protection headers at Pickering Units 5-8 are supplied by the station High Pressure Service Water (HPSW) pumps and not dedicated fire pumps (per Design Manuals NK30-DM-71400-00001 R006, "Fire Protection System" [B.22-8] and NK30-DM-71340-00001 R002, "High Pressure Service Water System" [B.22-9]). Therefore, NFPA 20 is not applicable to Pickering Units 5-8.

Pickering Units 1,4

AECL Report 44RS-00531-AB-001 Rev. 01, "Methodology for Review of Pickering A Design Against Current Regulations and Standards" [B.22-10] lists NFPA 20 as a "Code and Standard typically used for CANDU Nuclear Generating Stations". No review was performed, since Pickering A did not have dedicated fire pumps at the time. Similarly, reviews were not performed as part of the 2011 or 2000 Pickering A Fire Protection CCR assessments ([B.22-11], [B.22-12] respectively).

Per OPG Letter NA44-CORR-00531-06269 R000, "Pickering "A" - Installation of Diesel Engine Driven Fire Pumps (MEC 91665)" [B.22-13], the fire protection headers at Pickering A were originally supplied by the station HPSW pumps. During the determination of the proposed end state for the Units 2 and 3 HPSW systems (following the OPG decision not to restart these units), it was identified that the capacity of the Class III HPSW systems on Units 1 and 4 was not sufficient to supply the combined Class III HPSW loads and station fire water requirements under a Loss of Bulk Electrical Supply scenario if the Units 2 and 3 Service Water systems were shut down. Following a detailed review of options to satisfy the combined firewater / Class III demand, four new diesel firewater pumps were installed to supply the full Units 1,4 firewater load. The four pumps, which are located in the Pickering A Screenhouse pump pit area, are each designed to supply 50% of design water flow rate and are started sequentially on falling pressure with a time delay to allow the running pump(s) to recover fire header pressure before an additional pump is started ([B.22-14], [B.22-15]). Monthly and yearly Safety Related Systems Tests are performed on the pumps as outlined in [B.22-16] and [B.22-17].

Per Section 2.6 of the Modification Design Requirements (MDR) for the Pickering Units 1,4 firewater pumps [B.22-18]: "The new fire pump system shall meet the performance requirements specified in NFPA-20". Similar statements are made in the MDR with respect to the Pickering Units 1,4 firewater pumps meeting NFPA 20 mandated piping, civil design, instrumentation and control, periodic inspection and commissioning requirements, per Sections 2.1, 2.3, 2.4, 2.14 and 2.17 of [B.22-18]. Analogous statements are also made in the Design Plan for the installation of the fire pumps [B.22-19]. Per OPG Drawing NA44-DRAW-71410-10005 R000, "Pickering NGS A Screenhouse Diesel Fire Pumps Flow Diagram" [B.22-20], the 2003 version of NFPA 20 was used for the installation of the Pickering Units 1,4 firewater pumps. Pickering Units 1,4 compliance against the more recent (i.e., 2007, 2010, 2013 and 2016) versions of NFPA 20 is addressed under Section B.22.2.2 below.

Darlington NGS

OPG Reports NK38-REP-03680-10050 R000, "Review of NFPA-20, Standard for the Installation of Stationary Pumps for Fire Protection - 2007 Edition for Darlington ISR" [B.22-21] and NK38-REP-03680-10127 R001, "Gap Analysis to NFPA 20 2007 Edition, for DNGS Fire Protection Booster Pumps for Darlington ISR" [B.22-22] were prepared to assess compliance against the 2007 version of NFPA 20 for the Darlington ISR. A follow-up Code Refresh review of the 2013 version of NFPA 20 was also prepared in OPG Report NK38-REP-03680-10182 R000, "Code Refresh of NFPA 20, Standard for the Installation of Stationary Pumps for Fire Protection, 2013 Edition" [B.22-23]. Thirteen minor gaps were identified. OPG Report NK38-REP-03680-10104-ADD-002 R000, "Darlington NGS ISR - Final ISR Report Addendum 002" [B.22-24] provided updates to issues, classifications, justifications, and plans for the gaps identified in the above reviews. OPG Report NK38-REP-03680-10201 R001, "ISR Open Issues and Acceptable Deviations - Adequacy Review" [B.22-25] undertook a systematic approach to confirm previously discussed justification for the gaps being Acceptable Deviations and to confirm the adequacy of the safety improvements proposed for open issues. All issues were classified as Acceptable Deviations with a very low safety significance and no follow-up required.

The Darlington ISR review findings are not discussed further due to limited station-specific applicability to the Pickering Unit 1,4 firewater pumps.

B.22.2.2 Application of Post PSR1 Reviews

The baseline for Pickering Units 1,4 NFPA 20 compliance is the 2003 version of the standard. Therefore, the changes to NFPA since 2003 are discussed below.

The following information on recent revisions to the standard is taken from the current 2016 edition of NFPA 20 [B.22-1]:

> *For the 2007 edition, requirements for variable speed drives were refined, requirements for break tanks were added, and component replacement testing tables were included.*
>
> *The 2010 edition included a new chapter on fire pumps for high-rise buildings. Requirements for pumps arranged in series were also added to the general requirements chapter. Chapter 11 of the standard was reorganized.*
>
> *The 2013 edition clarified and added new requirements for water mist positive displacement pumping units. Chapter 5 of the standard was reorganized. Limited service controller requirements were revised, and the component replacement table was removed.*
>
> *The 2016 edition of NFPA 20 provides new requirements for pumps in series relative to protection of control wiring, status signals, and communications. NFPA 20 recognizes the potential use of multistage, multiport pumps in fire suppression systems and provides requirements specific to that application. Break tank criteria have been removed and are now in accordance with NFPA 22, Standard for Water Tanks for Private Fire Protection. A new annex, Annex C, has been added to provide guidance on controller security where a controller is connected to the Internet. New requirements have been added to address use of an automatic fuel maintenance system with a diesel fire pump installation. In addition, protection criteria for both a diesel fire pump room and an electric fire pump room are defined in Chapter 4.*

With respect to the 2007 NFPA 20 additions, variable speed drives are applicable to electric pumps. The firewater pumps for Pickering Units 1,4 are diesel pumps, and therefore, these changes are not applicable. For changes relating to break tanks, the current 2016 edition of NFPA 20 [B.22-1] states "Break tank criteria have been removed and are now in accordance with NFPA 22, "Standard for Water Tanks for Private Fire Protection"." Component replacement testing tables were also removed in subsequent editions of NFPA 20 and are now in accordance with NFPA 25, "Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems". As noted in NFPA 20 2016 [B.22-1], acceptance test criteria for replacement of critical path components of a fire pump installation were already part of NFPA 20 2003.

With respect to the 2010 NFPA 20 additions, fire pumps for high-rise buildings are not applicable to Pickering NGS. As per NA44-DRAW-71410-10005 R000, "Pickering NGS A Screenhouse Diesel Fire Pumps Flow Diagram" [B.22-26], the two sets of fire pumps in the East/West Screenhouse pump pits are arranged in parallel. Therefore, the revised 2010 NFPA general requirements associated with pumps arranged in series are also not applicable to Pickering NGS.

OPG Memorandum N-CORR-00590-0477036 [B.22-27] assessed the changes between the 2013 and 2010 versions of NFPA 20 and identified that all changes were either editorial or were not significant technical changes. Therefore, there are no significant changes that are relevant to the Pickering Units 1,4 firewater pumps.

OPG Report N-REP-00590-00014 R001, "Code-over Code Review Report: Code over Code Review for NFPA 20-2016 Vs. NFPA 20-2013" [B.22-28] assessed the changes between the 2016 and 2013 versions of NFPA 20 and identified ten significant technical changes to be added to OPG List N-LIST-00590-00001 R002, "List of Significant Technical Changes from Code-over-Code Review" [B.22-29]. As noted in N-LIST-00590-00001 R002 [B.22-29]:

> *Changes identified as Significant Technical Changes that do not require immediate compliance or review of OPG existing installations are listed in this document. Projects for modifications to existing installations or new installations shall use the listed Significant Technical Changes, as appropriate.*

Nine of the changes identified in N-REP-00590-00014 R001 [B.22-28] are new requirements for series fire pumps and are not applicable to Pickering Units 1,4 firewater pumps as discussed earlier. The tenth change is a new requirement for circulation relief valve setpoint pressure and is related to NFPA 20 2016 Clause 4.12.1.1 that states: "Where an electric variable speed pressure limiting controller is installed, the automatic circulation relief valve shall be set to a minimum of 5 psi (0.34 bar) below the operation set pressure." This clause is applicable to electric pumps in order to control the speed of the pump. The firewater pumps for Pickering Units 1,4 are diesel pumps, and therefore, this clause does not apply.

Based on the above, there are no significant changes from the 2003 version of NFPA 20 that have an impact on nuclear safety. As a result, Pickering Units 1,4 firewater pumps meet the intent of NFPA 20 (2016) [B.22-1].

B.22.3 Compliance Summary for Pickering PSR2

There are no PSR2 gaps for NFPA 20 (2016) [B.22-1]. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with NFPA 20 (2016).

B.23 NFPA 24 (2016), "Standard for the Installation of Private Fire Service Mains and Their Appurtenances"

B.23.1 Background

The following excerpts paraphrased from NFPA 24 (2016) [B.23-1] provide a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of NFPA 24 is to provide a reasonable degree of protection for life and property from fire through installation requirements for private fire service main systems based on sound engineering principles, test data, and field experience. The standard helps to ensure water supplies are available in a fire emergency. NFPA 24 provides minimum requirements for the installation of private fire service mains and their appurtenances, which includes supplying automatic sprinkler systems, open sprinkler systems, water spray fixed systems, foam systems, private hydrants, monitor nozzles or standpipe systems with reference to water supplies, and hose houses.*
>
> *NFPA 24 defines the requirements that govern water supplies, valves, hydrants, hose houses and equipment, master streams, underground and aboveground piping, and hydraulic calculations.*

NFPA 24 is relevant to Safety Factor 1 (Plant Design).

Compliance with NFPA 24 is not a licence requirement for Pickering NGS (PROL 48.02/2018), although it is referred to in the R04 Pickering Licence Conditions Handbook [B.23-2]. It may be considered an indirect licence requirement as CSA N293-07, "Fire Protection for CANDU Nuclear Power Plants" [B.23-3] is a licence requirement and refers to NFPA 24 as follows:

> *5.1.3 Where specific design or operational requirements are not addressed in this Standard, the NBCC [National Building Code of Canada], or the NFCC [National Fire Code of Canada], good engineering practice shall apply and, where appropriate, recognized Standards (such as those of the National Fire Protection Association [NFPA]) shall be used.*
>
> *7.3.2.3 The fire protection water distribution system shall be provided in accordance with NFPA 24.*

It is noted that OPG has been actively working on risk reduction plans to address higher risk areas, including internal fires at Pickering Units 1,4, with the objective of reducing Pickering Units 1,4 risk for both Severe Core Damage Frequency and Large Release Frequency. These risk reduction plans include further refinements to the fire Probabilistic Safety Assessments (PSAs) ([B.23-4], [B.23-5]) to address potential over-conservatisms in the existing results, as well as potential physical plant and operational changes intended to reduce overall risk. The fire PSA results have highlighted the increased importance of fire to site risk at Pickering NGS, and as a result this NFPA 24 review focuses on identifying any nuclear safety significant findings that may impact fire water supplies. P-LIST-71400-00001 R000, "Application of CSA N293-07 to Structures, Systems and Components for Pickering Nuclear" [B.23-6] was prepared by OPG to identify the Structures, Systems and Components (SSCs) within the protected area that are exempt from the application of N293-07, and the structures outside the protected area that need to align with N293-07. P-LIST-71400-00001 R000 has been utilized in this NFPA 24 review to identify fire water supply credits at Pickering NGS. P-LIST-71400-00001 R000 also identifies the exempted SSCs which have no impact on systems availability to achieve and maintain safe shutdown, as per the Fire Safe Shutdown ([B.23-7], [B.23-8]) and Fire Hazard ([B.23-9], [B.23-10]) Analyses.

NFPA 24 (2016) is the fifteenth edition of this standard, and supersedes the previous edition published in 2013. Other recent editions include changes in 2010 and 2007. The Preface of the current 2016 edition of NFPA 24 [B.23-1] provides information on recent changes which will be discussed in Section B.23.2.2.

The results of PSR1 NFPA 24 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.23.2. As identified in Reference [B.23-11], the Pickering PSR2 review of NFPA 24 (2016) is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- <u>Compliance:</u> Compliance indicates that the change in the safety requirement, per the topical review, is met.
- <u>Gap</u>: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.23.2 Compliance Assessment for Pickering PSR2

B.23.2.1 Application of PSR1 Reviews

The versions of NFPA 24 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

<u>Pickering Units 5-8</u>

No review was performed against NFPA 24 as part of the Pickering B ISR. OPG Report NK30-REP-03680-00001 R000, "Pickering NGS-B Integrated Safety Review - Plant Design Safety Factor" [B.23-12] discusses NFPA 20 in terms of other standards requiring general compliance with NFPA standards (e.g., CSA N293-07 [B.23-3] which states: "…where appropriate, recognized Standards (such as those of the National Fire Protection Association [NFPA]) shall be used").

Although a review against NFPA 24 was not prepared as part of the Pickering B ISR, reviews against NFPA 24 were performed as part of the 2000 and 2010 Pickering B Fire Protection Code Compliance Review (CCR) assessments ([B.23-13], [B.23-14] respectively). Per Section 2.4 of

OPG Report NK30-REP-71400-10001 R001, "Fire Protection Code Compliance Review Pickering Nuclear Generating Station B" [B.23-14], the 1970 version of NFPA 24 was reviewed as part of the Pickering B CCR. NFPA 24 was also reviewed in the context of the CCR review [B.23-14] of the 1969 version of NFPA 11, "Foam Extinguishing Systems" and 1972 version of NFPA 13, "Standard for the Installation of Sprinkler Systems" which also specify requirements for underground mains.

Section 3.7 of NK30-REP-71400-10001 R001 [B.23-14] describes the deviations identified against NFPA 24 as follows (text in italics is taken verbatim):

- NFPA 1970 Section 3601: *Deviation - Yard post indicator valves are not provided with industry-standard signs, which indicate section or portion of underground system controlled as required by code (Deviation # 04801). Technical Resolution - Current fire safety standards require that identification signs be provided to indicate the valve function and what it controls. The existing tags provide identification however the tags are difficult to read in some cases. Also, the tags do not readily indicate what section of the underground system is controlled by the valve. It is common practice in industrial facilities to identify valves by painting their identification number either on the valve post or a sign attached to the bumper post. Of the valves inspected, most were provided with a tag, however a general review of the valve identification should be made. Recommended Action - Valves in the exterior fire main loop should be inspected for proper identification and legibility of information. Action Status - Resolved… No further action required.*

- NFPA 1970 Section 3303: *Deviation - Yard post indicator valves at PNGS B are not installed at the code required 36 inches above finish grade (Deviation #'s 03201 and 09919)). Technical Resolution – The main intent of the requirement is to ensure that the top of the valve is at a reasonable height to permit correct and easy operation of the valve. The height difference will not prevent the operation of the valve. Disposition – Noncompliance - Acceptable. Recommended Action - No action required.*

- NFPA 1970 Section 3601: *Deviation - Yard post indicator valves at PNGS B are not secured in the open position as required by code (Deviation # 13301). Technical Resolution - To ensure that water is available at hydrants, hose stations and foam systems when required by emergency responders, the yard post indicator valves [PIVs] controlling the water supply to hydrants and systems on the site must remain open at all times. Where electronic supervision of control valves is not provided, such valves should be locked in the open position or sealed and inspected on a monthly basis. Recommended Action - Post indicator valves that are not electronically supervised should be locked in the open position or sealed and checked on a monthly basis. Action Status - Outstanding… Yard PIV's serving fire water systems should be either locked in the open position with chains or locks or equipped with supervisory monitoring switches connected to the station fire alarm systems.*

Based on the above, Deviations # 04801, 03201 and 09919 have been resolved. These resolutions are not impacted by Pickering NGS operation past 2020. Outstanding Deviation # 13301, which applies to Pickering Units 1,4 as well as Units 5-8, is currently in progress with locks installed on the majority of the affected valves. As discussed earlier, OPG List P-LIST-

71400-00001 R000 [B.23-6] identifies the SSCs within the protected area that are exempt from the application of N293-07, and the structures outside the protected area that need to follow N293-07. Exempted SSCs "have no impact on systems availability to achieve and maintain safe shutdown as per the fire safe shutdown analysis" [B.23-6]. Based on P-LIST-71400-00001 R000, there are a number of SSCs in the yard which directly support plant operation and which are defined as being "related to nuclear safety". As a result, fire water supply to these SSCs is a credited safety function. Since Deviation # 13301 is not yet complete, this deviation is nuclear safety significant and is identified as **PSR2 NFPA 24 Gap #1**.

Pickering Units 5-8 compliance against the 2016 version of NFPA 24 is addressed under Section B.23.2.2 below.

Pickering Units 1,4

AECL Report 44RS-00531-AB-001 Rev. 01, "Methodology for Review of Pickering A Design Against Current Regulations and Standards" [B.23-15] lists NFPA 24 as a "Code and Standard typically used for CANDU Nuclear Generating Stations". A review against NFPA 24 was not performed as part of Pickering A Return to Service. Reviews were also not performed against NFPA 24 as part of the 2000 or 2011 Pickering A Fire Protection CCR assessments ([B.23-16], [B.23-17] respectively). As a result, there is no "baseline" NFPA 24 compliance assessment available for Pickering Units 1,4. Since compliance has not been formally documented, this is identified as a PSR2 gap (**PSR2 NFPA 24 Gap #2**).

The safety significance of this PSR2 gap is discussed in more detail under Section B.23.2.2 below. In particular, Pickering A Firewater Pipe Replacement Project 13-80069 has replaced various sections of the buried fire protection piping in the north and south yards in the Pickering A un-zoned area. This proactive modification was undertaken to replace the existing grey cast iron piping, which was prone to failure, with PVC piping. As identified in OPG Project Charter NA44-PCH-71450-00001 R000, "Project Charter Buried Fire Pipe Replacement" [B.23-18], the main goals of the project are to eliminate isolation of major fire suppression systems due to buried pipe failures, minimize future failures of the buried grey cast iron pipe, and limit any future failures to lower consequence areas. The new portions of piping will be installed in accordance with NFPA 24. Given that the scope of the project includes the highest risk portions of piping, the consequence of failure of the remaining portions of the piping is considered to be low.

Darlington NGS

OPG Reports NK38-REP-03680-10051 R000, "Review of NFPA-24, Standard for the Installation of Private Service Mains and Their Appurtenances - 2007 Edition for Darlington Integrated Safety Review" [B.23-19] and NK38-REP-03680-10176 R002, "Gap Analysis to NFPA 24 2007 Edition, for DNGS Fire Protection Water Supply and Distribution System for Refurbishment" [B.23-20] identified Darlington NGS gaps against the 2007 version of NFPA 24. OPG Report NK38-REP-03680-10181 R000, "Code Review Refresh of NFPA 24, Standard for the Installation of Private Service Mains and Their Appurtenances, 2013 Edition" [B.23-21] reviewed the changes to NFPA 24 from the 2007 edition to the 2013 edition and identified three additional gaps. OPG Report NK38-REP-03680-10201 R001, "ISR Open Issues and Acceptable Deviations

- Adequacy Review" [B.23-22] later classified all NFPA 24 gaps as Acceptable Deviations with a very low safety significance and no follow-up required.

These gaps are not applicable to Pickering NGS; however, the safety significance of the findings is generally applicable to Pickering NGS, as discussed under Section B.23.2.2 below.

B.23.2.2 Application of Post PSR1 Reviews

For Pickering Units 5-8, the baseline for NFPA 24 compliance is the 1970 version of the standard. The following information on recent revisions to the standard is taken from the Preface of the current 2016 edition of NFPA 24 [B.23-1]:

> *In 1953, on recommendation of the Committee on Standpipes and Outside Protection, the two standards (NFPA 24 and NFPA 25) were completely revised and adopted as NFPA 24. Amendments were made leading to separate editions in 1955, 1959, 1962, 1963, 1965, 1966, 1968, 1969, 1970, 1973, 1977, 1981, 1983, and 1987.*
>
> *The 1992 edition included amendments to further delineate the point at which the water supply stops and the fixed fire protection system begins. Minor changes were made concerning special topics such as thrust restraint and equipment provisions in valve pits.*
>
> *The 1995 edition clarified requirements for aboveground and buried piping. Revisions were made to provide additional information regarding listing requirements, signage, valves, valve supervision, hydrant outlets, system attachments, piping materials, and thrust blocks. User friendliness of the document was also addressed.*
>
> *The 2002 edition represented a complete revision of NFPA 24. Changes included reorganization and editorial modifications to comply with the Manual of Style for NFPA Technical Committee Documents. Additionally, all of the underground piping requirements were relocated into a new Chapter 10.*
>
> *The 2007 edition was revised in five major areas: Chapter 10 was editorially updated and minor technical changes were made. In addition, newly established leakage test criteria, well as updated requirements for thrust blocks and restrained joints were added to Chapter 10. Two annexes were new to this edition: Annex C, Recommended Practice for Fire Flow Testing, and Annex D, Recommended Practice for Marking of Hydrants. These two annexes were developed based on the 2002 edition of NFPA 291.*
>
> *The 2010 edition was revised in three major areas: the provisions for location and identification of fire department connections [FDCs], valves controlling water supply, and protection of service mains entering the building.*
>
> *The 2013 edition of NFPA 24 included clarifications on the requirements for running piping under buildings, including annex figures depicting clearances. The Contractors Material and Test Certificate for Underground Piping (Figure 10.10.1) was modified to include confirmation that the forward flow test of the backflow preventer had been conducted. A provision requiring the automatic drip valve to be located in an accessible location that permits inspections in accordance with NFPA 25 was also added.*

NFPA 24 underwent a structural rewrite for the 2016 edition. The hydrant definitions have been clarified to describe the type of hydrant in question, as opposed to describing when and where they would be used. The valve arrangement requirements have been rewritten for clarity, and annex figures added to provide figures that are consistent with NFPA 13. The title of Chapter 6 has been changed from "Valves" to "Water Supply Connections," to better describe the material covered within the chapter. Revisions to Section 6.1 better call out the permitted exceptions to indicating valves and permit nonlisted tapping sleeve and valve assemblies in connections to municipal water supplies. The center of hose outlet measurements have been updated to include clear minimum and maximum values for the location of the outlet, along with the appropriate measurement for a hose house installation. The steel underground piping references have been removed from the table in Chapter 10 since steel pipe is required to be listed other than in the FDC line. A statement also has been added to allow underground fittings to be used above ground to transition to aboveground piping.

With respect to the significance of recent changes to the 2013 and 2016 editions of NFPA 24, OPG Memorandum N-CORR-00590-0477037, "Code-over-Code Review of NFPA 24, Standard for the Installation of Private Service Mains and Their Appurtenances - 2013 Edition over the 2010 Edition" [B.23-23] identified no significant technical changes and no mitigation requirements. OPG Report N-REP-00590-00015 R001, "Code-over Code Review Report: Code over Code Review for NFPA 24-2016 VS NFPA 24-2013" [B.23-24] concluded:

> *With respect to our review of the changes to the NFPA 24, 2016 Edition, no significant technical changes were identified which would impact the use of NFPA 24 at OPG nuclear generating stations. As such, no mitigation plans are proposed.*

However, N-REP-00590-00015 R001 identified two significant technical changes to be added to N-LIST-00590-00001 R002, "List of Significant Technical Changes from Code-over-Code Reviews" [B.23-25] for use in future modifications or new-build. These new requirements relate to the installation of fire mains under a building, and a new requirement for backfill. As noted in N-LIST-00590-00001 R002 [B.23-25]:

> *Changes identified as Significant Technical Changes that do not require immediate compliance or review of OPG existing installations are listed in this document. Projects for modifications to existing installations or new installations shall use the listed Significant Technical Changes, as appropriate.*

All modifications require review of N-LIST-00590-00001 R002, as identified in N-FORM-10959 R016, "Design Scoping Checklist" [B.23-26], as per N-PROC-MP-0090 R014, "Modification Process" [B.23-27] (N-FORM-10959 R016 Section 2.19 requires that a review of N-LIST-00590-00001 R002 "shall be completed to determine if any code change improvement actions apply to the modification"). Significant technical changes will be applied in accordance with the most recent versions of NFPA 24, as appropriate, for modifications to existing Pickering NGS installations going forward in accordance with OPG governance. Therefore, the Engineering Change Control (ECC) process, together with a yearly examination of any incremental (Code-over-Code) review requirements due to changes to NFPA 24 [B.23-28], ensure that any design changes made to the Pickering NGS firewater system comply with the latest version of NFPA 24 going forward. Furthermore, per the R04 Pickering Licence Conditions Handbook [B.23-2], any changes that have the potential to impact fire protection are assessed for compliance with CSA N293-07 and, if required, an external third party review is performed and the results submitted to the CNSC. Per OPG Report N-REP-09076-10006 R000, "Review of Design Requirements of CSA N293-07" [B.23-29], the process presently implemented by OPG in the ECC process for modifications which have the potential to impact fire safety is: a) all modifications will be screened and those having potential for fire impact will receive a detailed review, b) those modifications screened as having potential to impact fire safety will be submitted to a qualified third party for review, and c) the qualified third party must not be in the same management and financial operation as the design organization.

Nevertheless, for Pickering Units 5-8 the baseline for NFPA 24 compliance is the 1970 version of the standard, and Pickering Units 1,4 have not been previously assessed against NFPA 24. Although recent changes to the 2013 and 2016 versions of NFPA 24 will be addressed in any firewater system design changes going forward, existing (as-built) Pickering Units 1,4 and 5-8 fire service mains compliance has not been formally documented against the most recent versions of NFPA 24. Further, there have been a large number of significant changes since the Pickering Units 5-8 fire service mains were last reviewed against NFPA 24 (in 1970), including (as mentioned above) the 2002 edition which "represented a complete revision of NFPA 24". Since Pickering NGS has not demonstrated compliance with the 2016 version of NFPA 24, this has been identified as a PSR2 gap (**PSR2 NFPA 24 Gap #2**) as discussed earlier.

With respect to the retroactive application of NFPA 24 to Pickering NGS, it is generally not practicable to make design changes to the fire service mains without rebuilding it (or parts of it). Furthermore, if a fundamental change in understanding occurs that could have a negative impact on safety, this is addressed in a timely fashion through Industry Operating Experience (OPEX) and associated design changes as required. For example, OPG Letter NA44-CORR-00531-07592 R000, "Submission of Fire Protection Independent Third Party Code Compliance Review for Pickering A Firewater Pipe Replacement Project 13-80069" [B.23-30] and associated OPG Report NA44-REP-71400-00034 R000, "Pickering A Buried Piping Third Party Review" [B.23-31] document the recent Pickering A Buried Fire Piping Replacement Project that has replaced various sections of the buried fire protection piping in the north and south yards in the Pickering A un-zoned area. This proactive modification was undertaken to replace the existing grey cast iron piping, which was prone to failure, with PVC piping. Section 2.0 of NA44-DCS-71450-00001 R000, "Detailed Commissioning Specification for 13-80069 PA Buried Fire Pipe Replacement" [B.23-32] states:

1. *The new underground piping shall be completely flushed before tie-in to fire protection system piping in accordance with NFPA 24.*

2. *Hydrostatic testing shall be performed in accordance with NFPA 24.*

As discussed earlier, OPG Project Charter NA44-PCH-71450-00001 R000 [B.23-18] states that the main goals of the project are to eliminate isolation of major fire suppression systems due to buried pipe failures, minimize future failures of the buried grey cast iron pipe and limit any future failures to lower consequence areas. Given that the scope of the project includes the highest risk portions of piping, the consequence of failure of the remaining portions of the piping is considered to be low.

Finally, as per NK30-CORR-00531-06032 R000, "Pickering B - Response to CNSC Action Item 20118-2289 - Type II Inspection of Fire Protection Water Supply Systems" [B.23-33], buried fire protection systems are included in the scope of N-PROC-MA-0088 R003, "Buried Piping Program Requirements" [B.23-34]. System piping is required to be tested every 5 years in accordance with NFPA 25, "Standard for the Inspection, Testing and Maintenance of Water-Based Fire Protection Systems". The requirement involves conducting flow tests of system piping to determine the internal condition of the buried piping. Pickering NGS exceeds the minimum testing requirement, and tests fire protection piping annually per Pickering Unit 018 Nuclear Operating Procedure P-OP-71450-0001 R004, "PNGS Semi-Annual Yard Fire Hydrant Inspection/Flow Test and Annual Hydrant Isolating Valve Maintenance" [B.23-35].

B.23.3 Compliance Summary for Pickering PSR2

There are two PSR2 gaps for NFPA 24 (2016) [B.23-1] which relate to Safety Factor 1 (Plant Design):

1. For OPG Report NK30-REP-71400-10001 R001, "Fire Protection Code Compliance Review Pickering Nuclear Generating Station B", there is an outstanding issue (Deviation # 13301) which relates to NFPA 24 1970 Section 3601: "Yard post indicator valves at PNGS B are not secured in the open position as required by code" (and which applies to Pickering Units 1,4 as well as Units 5-8). Work to resolve this deviation is currently in progress with locks installed on the majority of the affected valves. Based on OPG List P-LIST-71400-00001 R000, there are a number of Structures, Systems and Components (SSCs) in the yard which directly support plant operation and which are defined as being "related to nuclear safety". As a result, fire water supply to these SSCs is a credited safety function. Deviation # 13301 is not yet complete. Therefore, this has been identified as a PSR2 gap.

2. For Pickering Units 5-8 the baseline for NFPA 24 compliance is the 1970 version of the standard. Pickering Units 1,4 have not been previously assessed against NFPA 24. Although recent changes to the 2013 and 2016 versions of NFPA 24 will be addressed in any firewater system design changes going forward (as a result of Code-over-Code reviews performed for NFPA 24), compliance has not been formally documented for Pickering Units 1,4 or Units 5-8 against the most recent versions of NFPA 24. Furthermore, there have been a large number of significant changes to NFPA 24 since 1970, including the 2002 edition which "represented a complete revision of NFPA 24". Since Pickering NGS has not demonstrated compliance with the 2016 version of NFPA 24, this has been identified as a PSR2 gap. It is noted that OPG is proactively replacing portions of the firewater piping in accordance with NFPA 24, under the Pickering A Firewater Pipe Replacement Project 13-80069.

B.24 CNSC REGDOC-2.5.2 (2014), "Design of Reactor Facilities: Nuclear Power Plants"

B.24.1 Background

The following paraphrase from the purpose and scope of CNSC REGDOC-2.5.2 (2014) [B.24-1] provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *REGDOC-2.5.2 sets out the requirements of the Canadian Nuclear Safety Commission (CNSC) for the design of new water-cooled nuclear power plants (NPPs, or plants). It establishes a set of comprehensive design requirements and guidance that are risk-informed and align with accepted national and international codes and practices.*
>
> *REGDOC-2.5.2 deals with a wide variety of topics related to the design of new NPPs. To the extent practicable, this document is technology-neutral with respect to water-cooled reactors, and includes requirements and guidance for:*
>
> - *establishing the safety goals and objectives for the design*
> - *utilizing safety principles in the design*
> - *applying safety management principles*
> - *designing structures, systems and components (SSCs)*
> - *interfacing engineering aspects, plant features and facility layout*
> - *integrating safety assessments into the design process*
>
> *To a large degree, REGDOC-2.5.2 represents the CNSC's adoption of the principles set forth in the International Atomic Energy Agency (IAEA) document SSR-2/1, Safety of Nuclear Power Plants: Design, and the adaptation of those principles to align with Canadian practices.*
>
> *It is recognized that specific technologies may use alternative approaches. If a design other than a water-cooled reactor is to be considered for licensing in Canada, the design is subject to the safety objectives, high-level safety concepts and safety management requirements associated with this regulatory document. However, the CNSC's review of such a design will be undertaken on a case-by-case basis.*
>
> *Conventional industrial safety is addressed only from a high-level perspective, with a focus on design requirements that are related to nuclear safety.*

REGDOC-2.5.2 (R2014) is directly relevant to Safety Factors 1 (Plant Design), 5 (Deterministic Safety Analysis), 6 (Probabilistic Safety Assessment) and 7 (Hazard Analysis).

Compliance with REGDOC-2.5.2 is not currently a licence requirement Pickering NGS (in accordance with PROL 48.02/2018) [B.24-2] per the R04 Pickering Licence Conditions Handbook (LCH) [B.24-3].

CNSC REGDOC-2.5.2 is a first edition (version 1) and supersedes RD-337, Design of New Nuclear Power Plants [B.24-4], and consolidates the updated requirements and guidance related to the design of NPPs set out in draft RD-337 version 2, Design of Nuclear Power Plants [B.24-5], and draft GD-337, Guidance for the Design of New Nuclear Power Plants [B.24-6]. The following details on the changes presented by REGDOC-2.5.2 are obtained from the CNSC publication notice [B.24-7]:

> *The amendments to RD-337 included in this REGDOC ensure alignment with current national and international codes and practices, such* [as] *the principles set forth in the IAEA document SSR-2/1, Safety of Nuclear Power Plants: Design, with adoption of these principles to Canadian practices. Key changes adopted from the IAEA document include the added requirement for the design to explicitly consider the construction phase and expansion of the plant's fundamental safety functions to include cooling of all fuel (not just the core).*
>
> *REGDOC-2.5.2 implements recommendations from the CNSC Fukushima Task Force Report* [B.24-8] *including improved requirements for spent fuel storage, new requirements for mobile equipment, and more comprehensive coverage for design extension conditions.*

As identified in Reference [B.24-9], the Pickering PSR2 review of CNSC REGDOC-2.5.2 (2014) is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.
- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.24.2 Compliance Assessment for Pickering PSR2

As noted above, CNSC REGDOC-2.5.2 supersedes RD-337. In general, REGDOC-2.5.2 builds on the previous requirements in RD-337 while also introducing additional guidance for new plants. For the most part, clause numbering in REGDOC-2.5.2 is the same as that in RD-337, with any new requirements being assigned new sub-clause numbers. Both RD-337 and REGDOC-2.5.2 are aligned with the high level requirements in IAEA NS-R-1 and its superseding document, IAEA SSR-2/1 R0. For these reasons, PSR1 reviews for both RD-337 (Darlington) and IAEA NS-R-1 (Pickering B) are largely applicable and relevant to the PSR2 REGDOC-2.5.2 review. However, there are no directly applicable code reviews from Pickering A Return to Service.

The approach to this compliance assessment in Section B.24.2.1 is to review the results from the Pickering B PSR1 clause-by-clause review conducted against IAEA NS-R-1 and assess their impact on Pickering 1,4 and PSR2. The results from the Darlington PSR1 clause-by-clause review conducted against RD-337 are then assessed for potential impact on Pickering 5-8 and Pickering 1,4 for PSR2.

Section B.24.2.2 provides a review of Pickering against REGDOC-2.5.2. Gaps that were identified in the Darlington PSR1 RD-337 review are also identified and applicability to Pickering PSR2 addressed. Although, there are significant programmatic and high level design similarities between the Darlington and Pickering plants, there are enough design differences that Darlington conclusions cannot be readily applied to Pickering. For this reason, Section B.24.2.2 additionally performs a high level review of all the REGDOC-2.5.2 clauses with respect to their impact on Pickering PSR2.

There is significant overlap between requirements in REGDOC-2.5.2 and several other CNSC and CSA standards that are being assessed as part of PSR2. For any REGDOC-2.5.2 gaps against clauses that have the same requirements as those in another code review, the corresponding gap(s) from the other review will be identified rather than initiating a REGDOC-2.5.2 gap. If there are similar clauses, but REGDOC-2.5.2 introduces requirements beyond those in the other code reviews for which there is a Gap, a new REGDOC-2.5.2 gap is identified.

B.24.2.1 Application of PSR1 Reviews

The versions of REGDOC-2.5.2 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

<u>Pickering Units 5-8</u>

REGDOC-2.5.2 did not exist when the Pickering B Integrated Safety Review (ISR) was conducted. Pickering B conducted a compliance review against IAEA NS-R-1 as part of the Plant Design Safety Factor report [B.24-10]. The complete set of NS-R-1 Discrepancies and Acceptable Deviations are documented in the final ISR report [B.24-11] in Appendices C and D respectively. The Discrepancies have been extracted and summarized in the table below.

Pickering B ISR IAEA NS-R-1 Discrepancies

NS-R-1 Clause	Pickering B ISR Gap #	Topic	Comments
2.10 5.31 6.54 6.57 6.59 6.61 6.63	1-428 1-430 1-431 1-432 1-433 1-434 1-435	Severe Accidents	Addressed in Gap 6-393 below

NS-R-1 Clause	Pickering B ISR Gap #	Topic	Comments
6.69 6.42 A-3	1-436 1-458 1-464		
6.37 2.10 5.31 6.42 6.54 6.57 6.59 6.61 6.63 6.69	6-393	Severe Accident (SA) Management – Station specific program for Pickering B is being developed	Addressed in PSR1 Safety Analysis Safety Factor review below and in Section B.24.2.2.
5.12	1-429	Fire-Fighting Systems	Addressed in Gap 1-643 below
	1-643	A design review of CSA N293-07 has not been performed.	PSR2 has conducted a code review against N293-12.
5.14 5.17	1-440 1-440	Probabilistic Safety Assessment (PSA) External Events	Addressed in Gap 6-391 below
5.73	1-468	PSA Approach and Methodology	Addressed in Gap 6-391 below
5.73	6-391	Risk from External Events	Addressed in PSR1 Safety Analysis Safety Factor review below and in Section B.24.2.2.
5.24	1-441	Design Limits related to Defense in Depth	Addressed in PSR2 Safety Factor 1 Report for Plant Design and in Section B.24.2.2.
5.70	1-456 5-388 5-386	Deterministic Safety Analysis Modelling - Legacy Safety Analysis Codes, Analytical Methods	Gap 5-388 and 5-386 are addressed in PSR1 Safety Analysis Safety Factor review below and in Section B.24.2.2.
5.71	1-482	Deterministic Safety Analysis approach	Captured in 5-388 above
6.46	1-483	Containment Strength	Captured in 5-388 and 6-393
6.66	1-484	Containment – control and clean-up of atmosphere	Captured in 5-388 and 6-393
5.24, C.2.0	5-373	Ability to shutdown for Anticipated Operational Occurrences (AOOs)	Addressed in PSR1 Safety Analysis Safety Factor review below and in Section B.24.2.2.

NS-R-1 Clause	Pickering B ISR Gap #	Topic	Comments
5.31	6-394	Level 2 Probabilistic Risk Assessment (PRA)	Addressed in 6-393 above
6.54 6.57 6.59	6-398	Capability of Penetrations for and structures for SAs	Addressed in 6-393 above
6.63	6-400	Containment heat removal following a SA	Addressed in 6-393 above

In addition to these Discrepancies, Appendix D – Acceptable Deviations (ADs) in [B.24-11] of the final ISR report was reviewed. There were twelve Acceptable Deviations identified against IAEA NS-R-1 (Clauses 1.7, 3.8, 5.31, 5.34, 5.35, 5.37, 5.38, 5.41, 6.1, 6.64, 6.67, and 6.9). These ADs and their dispositions have been reviewed for applicability to Pickering Units 1,4. In each case the disposition provided for Pickering Units 5-8 is also applicable to Pickering Units 1,4. Therefore, there are no PSR2 gaps resulting from the Pickering B ISR NS-R-1 ADs.

The results of the NS-R-1 review from reference [B.24-10] relating to the Plant Design Safety Factor review are summarized below:

> *It was determined that most of the clauses of the IAEA Safety Standard NS-R-1 fall under the "Direct Compliance" or "Acceptable Deviation" categories. Nine clauses have been categorized as "Discrepancy" all of which fall under the severe accident analysis subject area. All nine clauses were identified as "Discrepancy" in the "Pickering NGS B - Integrated Safety Review – Safety Analysis Review" (Reference 8). This review did not identify any additional clauses categorized as "Discrepancy".*

As noted in the table above, the Safety Analysis Safety Factor review [B.24-12] highlighted the following gaps (in *italics*), which are discussed further in the pages that follow:

> ***Hydrogen behaviour in containment and mitigation***
>
> *As per Generic Action Item 88G02, there is debate regarding control of long-term hydrogen due to radiolysis and corrosion. Short-term hydrogen control is provided by the PLHIS (Post LOCA [Loss of Coolant Accident] Hydrogen Ignition System). This issue is considered to be an Acceptable Deviation since PLHIS has been environmentally qualified for a mission time of 30 days, and would therefore likely be available for hydrogen mitigation in the short term following a LOCA+LOECI [Loss of Emergency Coolant Injection]. This issue is also identified as a gap against requirements from NS-R-1 (Clause 6.64) and CNSC document R-7 (Clause 3.10.2).*

This gap concerning long-term control of hydrogen has been addressed for Pickering with the installation of Passive Autocatalytic Recombiners (PARs) and completion of the Fukushima Action Items [B.24-13]. Hence, it is not a PSR2 gap.

Qualification of safety analysis codes used in the Safety Report

Many legacy codes have not undergone complete verification and validation and these may need to be used to support safety assessments for life extension. Resolution of this issue may require gap assessments to be done to show that analysis results remain conservative. This issue is also identified as an Acceptable Deviation against requirements from NS-R-1 (Clause 5.70).

This issue is considered to be a gap for PSR2. However, this issue was included within the scope of an issue that was identified as a gap against REGDOC-2.4.1 "Deterministic Safety Analysis" [B.24-14]. Therefore, the above issue related to safety analysis codes is not an incremental PSR2 gap for REGDOC-2.5.2.

Anticipated Operational Occurrences

The concept of anticipated operational occurrences (AOOs) is relatively new in the Canadian licensing context for Safety Analysis… The more formal establishment of AOOs in the licensing framework appears in the draft CNSC Regulatory Document S-310.

This issue is considered to be a gap for PSR2. However, this issue is already included under a Deterministic Safety Analysis REGDOC-2.4.1 [B.24-14] methodology gap and is, therefore, not an incremental PSR2 gap for REGDOC-2.5.2.

Probabilistic Safety Assessment

As a result of the limitations in scope of the existing PRA, deficiencies have been identified relating to development and use of Probabilistic Risk Assessments. In terms of modern codes and standards, OPG does not currently meet the intent of several IAEA requirements or clauses in S-294 (e.g., the PBRA [Pickering B Risk Assessment] currently does not include seismic and tornado events, or fire, as initiating events). However, S-294 allows assessment of events by other methods. OPG has addressed these events via hazard assessments and design (i.e., fire and seismic - refer to Appendix C, Section C.3.0).

It can be concluded that OPG and the Pickering B PRA are reasonably well aligned with the standards and requirements for modern PRAs.

While the Level-1 PBRA analysis is fully acceptable and usable, OPG is currently pursuing improvements to the Level 2 analysis.

This issue was addressed by OPG via the S-294 compliance program. However, a PSR2 Gap has been identified against REGDOC-2.4.2 Probabilistic Safety Analysis [B.24-15]. In addition, there are new requirements in REGDOC-2.5.2 which are discussed and addressed in Section B.24.2.2 below.

Application of Single Failure Criterion

The 'single failure' criteria as defined by the IAEA (NS-R-1 & NS-G-1.2) is different than that established by the CNSC in Regulatory Documents R-7, R-8 and R-9. NS-R-1 states the following:

> *"5.37. Compliance with the criterion shall be considered to have been achieved when each safety group has been shown to perform its safety function when the above analyses are applied, under the following conditions:*
>
> *(1) any potentially harmful consequences of the [Postulated Initiating Event (PIE)] for the safety group are assumed to occur; and*
>
> *(2) the worst permissible configuration of safety systems performing the necessary safety function is assumed, with account taken of maintenance, testing, inspection and repair, and allowable equipment outage times.*

Clearly stated acceptance criteria, objectives and safety goals are demonstrated to be met in the current Safety Report and the PBRA. From a design perspective, the single failure criterion is reflected in the CNSC Requirements for Special Safety Systems (R7, R8 & R9). These requirements do not specify that this criterion be applied at the limit of operation. For Pickering B, the approach has been to respond to address instances of no redundancy in systems important to safety with high priority per the impairments procedures. If the limit of operation is exceeded (an additional failure) and the safety function is not available, then immediate repair or controlled shut down is required.

The application of Single Failure Criterion was identified as a gap (Issue 1-443) in the NS-R-1 reviews and classified as an Acceptable Deviation. The CNSC requested this Acceptable Deviation be reclassified as a Discrepancy in [B.24-11] and OPG provided additional risk based rationale to support maintaining this gap as an Acceptable Deviation:

OPG provides the following additional information to support the categorization of this item as Acceptable Deviation. OPG recently initiated a new project, the Probabilistic Safety Assessment Project, in order to meet the operating license conditions to perform for OPG stations a level 2 Probabilistic Safety Assessment in accordance with the CNSC Standard S-294, Probabilistic Safety Assessment (PSA) for Nuclear Power Plants. The Pickering NGS-B Risk Assessment will be updated. Following the established practice, the methodology and the specific "risk assessment tools" to be used for the assessment will be discussed and agreed upon with the CNSC staff, prior to performing the actual assessment.

The CNSC continued to maintain that this issue was a PSR1 discrepancy. Subsequently, this issue was transferred to the Pickering B Continued Operations Plan [B.24-16], where it was closed on the basis that the Level 1 and Level 2 PSA demonstrated that the existing plant design satisfied all safety requirements. The applicability of the gap resolution and subsequent disposition is considered to be equally applicable to Pickering Units 1,4, where the PSAs have similarly been updated. Hence this issue is not a gap for PSR2.

In summary, there were four general areas where there were PSR1 gaps relating to Pickering B PSR1 IAEA NS-R-1 review. These were:

- Severe Accident Management and Assessment, including hydrogen mitigation and instrumentation for SA management – this gap is now closed.
- Fire-fighting and CSA N293 compliance – this gap is now closed.
- Deterministic Safety Analysis methodology (including treatment of AOOs, Code Qualification, Treatment of Human Initiating Events) - this is a PSR2 Gap and addressed in PSR2 REGDOC-2.4.1 review.
- Probabilistic Safety Assessment (including external events) - this is a PSR2 Gap and addressed in PSR2 REGDOC-2.4.2 review.

In addition, gaps relating to the following two clauses remained open or the CNSC requested re-categorization as discrepancies per [B.24-11], Appendix D:

- Validation of field actions for Design Basis Accidents (DBAs) (Clause 5.30).
  This issue has been addressed with the implementation of CNSC G-323 [B.24-17] at Pickering. Reference [B.24-18] identifies the assessments conducted to validate the credited field actions. Reference [B.24-19] documents the CNSC's acceptance of Pickering's Minimum Shift Complement and closes the related CNSC Action Items.

  OPG has conducted this analysis in accordance with G323 - Ensuring the Presence of Sufficient Qualified Staff at Class I Nuclear Facilities - Minimum Staff Complement and G-278 Verification and Validation. The analysis methodology, analysis and…

- Auxiliary Services (Clause 5.41)
  This issue has been addressed in Appendix D of [B.24-11] and maintained as an AD. In addition, the PSR2 review of CSA N290.0 has a similar clause relating to Special Safety Systems. The assessment for the clause in CSA N290.0 [B.24-20] is applicable to other safety-related systems. Hence, this is not a gap for PSR2.

The above gaps are resolved and do not represent PSR2 gaps.

It is concluded that all Discrepancies identified as part of the IAEA NS-R-1 review for the Pickering B ISR are captured as part of other PSR2 Safety Factor and Code Reviews, or were addressed as part of the ISR and Integrated Implementation Plan development and follow up activities. Due to their programmatic nature, all of the Pickering 5-8 issues and their resolutions identified above are also applicable to Pickering 1,4.

<u>Pickering Units 1,4</u>

REGDOC-2.5.2 did not exist when the Pickering A return to Service ISR was conducted and there were no assessments conducted against its predecessors (CNSC RD-337, S-337) or IAEA basis documents (e.g., NS-R-1).

Darlington NGS

REGDOC-2.5.2 did not exist when the Darlington ISR was conducted. Darlington conducted a review against CNSC RD-337 [B.24-21] in August 2011 and a subsequent review against IAEA NS-R-1 [B.24-22] in September 2011. As part of the code refresh activities, a review against IAEA SSR-2/1 was performed [B.24-23] in February 2014.

As noted in B.24.1, REGDOC-2.5.2 was an update of RD-337 to reflect Operating Experience (OPEX) from the Fukushima event and to align with IAEA SSR-2/1. However, per [B.24-23], the IAEA SSR-2/1 review did not identify any gaps incremental to those identified against IAEA NS-R-1. Hence, a combination of the review results from the RD-337 and IAEA NS-R-1 reviews provides a comprehensive basis for evaluating the relative compliance with REGDOC-2.5.2.

The results of the RD-337 review for Darlington are summarized below:

> *This review finds that the Darlington NGS-A design is compliant with the majority of the requirements of RD-337. Out of a total of 133 clauses of RD-337 which were assessed for compliance, only 37 gaps were found. The numbers of gaps, in brackets, are in the areas of:*
>
> - *Plant Design Provisions (10)*
> - *Severe Accidents / Beyond Design Basis Accidents (8)*
> - *Security (6)*
> - *Deterministic Safety Analysis (5)*
> - *Fire (4)*
> - *Probabilistic Safety Analysis (2)*
> - *Decommissioning (1)*
> - *Periodic Inspection Programs (1)*

The following identifies the issues from the Darlington ISR that required resolution and that were based on gaps resulting from the RD-337 code review [B.24-21] compiled in [B.24-24], and their applicability to Pickering PSR2.

D011 Changes to In-service Examination and Testing Requirements for Concrete Containment Structures

> *Clause 7.15.2 of CNSC RD-337 provides a list of requirements for design to facilitate inspection of civil structures. Gap 01470 states that DNGS is not fully compliant with the requirements of CAN/CSA-N287.7-08 based on the Gaps identified in NK38-REP-03680-10061.*

Although this issue is specific to containment structures, it refers to a related Issue D300 which is applicable to non-containment safety-related structures:

> *The gaps included in this Issue concern the requirements to conduct regular in-service examinations of safety-related structures for evidence of degradation. The structures covered include i) those that support, house or protect nuclear safety systems, ii) components of structures required for the safe operation or reactor shutdown, and iii) facilities for storage of irradiated fuel and other radioactive waste material. The Code review found that DNGS does not have an active program for in-service examination of safety-related structures, other than the periodic inspection programs for the concrete containment structures covered in the CAN/CSA-N287 series, or for the pressure-retaining systems and components covered in CAN/CSA-N285.0.*

Specific to inspection requirements for non-containment safety-related structures, the above gap also identifies issues with these structures. This is addressed in further detail under REGDOC-2.5.2 Clause 7.15.2 in Section B.24.2.2 below.

D013 Long Term Control of Hydrogen in Containment

> *Gap 01480 requires that the design of the nuclear power plant shall provide systems to control the release of fission products, hydrogen, oxygen, and other substances into the reactor containment as necessary, to:*
>
> *1. Reduce the amount of fission products that might be released to the environment during an accident; and,*
>
> *2. Prevent deflagration or explosion that could put the integrity or leak tightness of the containment envelope at risk.*
>
> *Gap 01481 describes the relationship between coatings inside containment and post-accident conditions inside containment (i.e., the production of hydrogen from metal corrosion). The gap states that no evidence exists to confirm that post-accident conditions inside containment were considered when choosing the type and quantity of coating for civil structures and steel lined reactor structures.*

These gaps were identified against Clauses 8.6.8 and 8.6.10 of CNSC RD-337. As noted above in the Pickering ISR review, treatment of Hydrogen does not represent a gap for PSR2. The gap relating to coatings is addressed under Issue D072 below.

D025 Darlington Risk Assessment (DARA) Scope and Completion

> *This ISR Issue consists of a total of ten (10) ISR Gaps from three (3) Code Review Reports.*
>
> - *Seven (7) Gaps are from NK38-REP-03680-10007, "Review of CNSC S-294 (April 2005) Probabilistic Safety Assessment (PSA) For Nuclear Power Plants For Darlington Integrated Safety Review".*

- *One (1) Gap is from NK38-REP-03680-10088 "Review of IAEA GS-R-2 (November 2002) Preparedness and Response for a Nuclear or Radiological Emergency for Darlington Integrated Safety Review".*

- *Two (2) Gaps are from NK38-REP-03680-10109, "Review of CNSC RD-337 (September 2008) Design of New Nuclear Power Plants for Darlington Integrated Safety Review"*

D025 Gaps from NK38-REP-03680-10109, "Review of CNSC RD-337 (September 2008) Design of New Nuclear Power Plants for Darlington Integrated Safety Review" Gap 01461 was declared against Clause 7.6.1 of CNSC RD-337 which requires consideration of Common Cause Failures. The Code Review Report, NK38-REP-03680-10109, found that a formal Common Cause Failures evaluation using probabilistic methods has not been performed.

Gap 01488 was declared against Clause 9.5 of CNSC RD-337 which requires a Probabilistic Safety Assessment in accordance with CNSC S-294. The Code Review Report, NK38-REP-03680-10109, found that a Darlington Risk Assessment fully compliant with CNSC S-294 has not yet been issued.

The gaps identified in this Issue have subsequently been addressed in the DARA update [B.24-25]. Similar to Darlington, the Pickering PSAs have been updated to address the same gaps identified in this issue. Hence, this issue is not a PSR2 gap for Pickering. Note that a separate review of REGDOC-2.4.2 has been performed as part of PSR2.

D027 Severe Accident and Beyond Design Basis Accident (BDBA) Analysis/ SAMG [Severe Accident Management Guidelines]

This ISR issue consists of a total of 17 ISR Gaps from two (2) Code Review Reports.

- *Two (2) gaps are from NK38-REP-03680-10102, "Review of CNSC RD-310 (February 2008) Safety Analysis for Nuclear Power Plants".*

- *Fifteen (15) Gaps are from NK38-REP-03680-10021, "Review of IAEA NS-G-1.2 (January 2002) Safety Assessment and Verification for Nuclear Power Plants For Darlington Integrated Safety Review".*

Although these gaps did not result from the RD-337 code review, the subject of accident analysis in Issue D027 was also identified in Clause 7.3.4 of the RD-337 review [B.24-21], and hence is included here. This issue is addressed in further detail specific to Pickering under the REGDOC-2.5.2 review in Section B.24.2.2 below.

D028 Systematic Analysis of Anticipated Operational Occurrences (AOOs)

Gap 01457 was declared against Clause 7.3.2 of CNSC RD-337 which contains various requirements for Anticipated Operational Occurrences, including: "The design includes provisions such that releases to the public following an Anticipated Operational Occurrence do not exceed the dose acceptance criteria". The Code Review Report, *NK38-REP-03680-10109, found that Anticipated Operational Occurrences have not been analysed.*

REGDOC-2.5.2 has the same requirement in Clause 7.3.2 and this issue is applicable to Pickering, however, it is being addressed under PSR2 REGDOC-2.4.1 (Deterministic Safety Analysis) review.

D030 Identification and Classification of Events per CNSC RD-310

This ISR issue consists of a total of nine (9) ISR Gaps from two (2) Code Review Reports:

- Five (5) ISR Gaps are from NK38-REP-03680-10102, "Review of CNSC RD-310 (February 2008) Safety Analysis for Nuclear Power Plants"
- Four (4) ISR Gaps are from NK38-REP-03680-10109, "Review of CNSC RD-337 (September 2008) Design of New Nuclear Power Plants for Darlington Integrated Safety Review"

Gap 01452 was declared against Clause 4.2.1 of CNSC RD-337 which requires that the committed whole-body dose for average members of the critical groups who are most at risk, at or beyond the site boundary is calculated in the deterministic safety analysis for a period of 30 days after the analyzed event. This dose is less than or equal to the dose acceptance criteria of 0.5 millisievert for any Anticipated Operational Occurrence or 20 millisieverts for any Design Basis Accidents. The Code Review Report, NK38-REP-03680-10109, found that activities designed to achieve compliance with CNSC RD-310 and map CNSC C-006 dose limits to new dose limits are not yet complete.

Gap 01454 was declared against Clause 6.4 of CNSC RD-337 which requires that the design includes provisions for the prevention and mitigation of radiation exposures resulting from Design Basis Accidents and Beyond Design Basis Accidents. The design also ensures that potential radiation doses to the public from Anticipated Operational Occurrences and Design Basis Accidents do not exceed dose acceptance criteria provided in subsection 4.2.1. The calculated overall risk to the public from all plant states meets the safety goals in subsection 4.2.2. The Code Review Report, NK38-REP-03680-10109, found that activities designed to achieve compliance with CNSC RD-310 and map CNSC C-006 dose limits to new dose limits are not yet complete.

Gap 01460 was declared against Clause 7.4.3 of CNSC RD-337 which requires that combinations of randomly occurring individual events that could credibly lead to Anticipated Operational Occurrences, Design Basis Accidents, or Beyond Design Basis Accidents are considered in the design. Such combinations are identified early in the design phase, and are confirmed using a systematic approach. The Code Review Report, NK38-REP-03680-10109, found that for certain low power states, normal operation, and for events from operating experience, the DNGS safety analysis may not comply and referred to Clause 5.2.1 of CNSC RD-310.

Gap 01487 was declared against Clause 9.4 of CNSC RD-337 which describes the purpose of deterministic safety analysis and references CNSC RD-310. The Code

Review Report, NK38REP-03680-10109, found that, based on the existence of Gaps with CNSC RD-310, such as those found to exist in the DNGS Design guides for events to be analysed, acceptance criteria, methods, and assumptions, this clause was also a Gap.

This issue of identification and classification of events from the Darlington ISR is applicable to Pickering NGS however it will be addressed as part of the review PSR2 CNSC REGDOC-2.4.1 (Deterministic Safety Analysis) review.

D040 Human Factors Design

This issue relates to Clauses 7.21 (Gap 1471) and 8.10.1 (Gap 1484) for Human Factors relating to the original Darlington Design. Additionally, this issue addresses gaps identified against IAEA NS-R-1 and SSR-2/1. All issues were closed in the Issue Resolution form [B.24-26]. This issue is addressed in further detail specific to Pickering under Clause 7.21 in Section B.24.2.2 below.

D260 Human Factors - Annunciation Improvements

This issue is documented in [B.24-27] and a summary of the issue is provided in the final ISR report [B.24-24]. The RD-337 clauses relating to this issue are 7.21 and 8.10.1 [B.24-21] and these are the same clauses in REGDOC-2.5.2. The Darlington gaps and issue relating to annunciations were closed based on the assessments in and referred to in [B.24-27]. Because of differences between the Pickering and Darlington annunciation system designs, the annunciation issue is not directly applicable to Pickering. This issue is addressed in further detail specific to Pickering under Clauses 7.21 and 8.10.1 in Section B.24.2.2 below.

D063 Seismic Qualification – General

Gap 01469 was declared against Clause 7.13.1 of CNSC RD-337 which requires that seismic fragility levels should be evaluated for Structures, Systems and Components important to safety, by analysis or, where possible, by testing. The Code Review Report, NK38-REP-03680-10109, found that seismic fragility assessments / Probabilistic Risk Assessment are currently in progress and therefore DNGS is currently not considered to be in compliance with Clause 7.13.1.

The Seismic PSAs have been completed for Pickering. However, as detailed in Section B.24.2.2 for Clause 7.13.1 of REGDOC-2.5.2 below, it has not been confirmed that the required margin between the Design Basis Earthquake (DBE) and Review Level Earthquake (RLE) meets the requirement for a new plant.

D068 Severe Accident and Beyond Design Basis Accident (BDBA) Design/SAMG

Grouped with D143 [B.24-28], Severe Accident and Beyond Design Basis Accident (BDBA) Program/SAMG, the gaps in these issues are as follows:

Gap 01456 was declared against Clause 7.2 of CNSC RD-337 which requires that the design authority establishes the plant design envelope, which comprises the design basis and complementary design features. Complementary design features address the performance of the plant in Beyond Design Basis Accidents, including selected *severe accidents. The Code Review Report, NK38-REP-03680-10109, found that design features to cater to severe accidents were not part of the original design.*

Gap 01458 was declared against Clause 7.3.4 of CNSC RD-337 which contains various specific design requirements for Beyond Design Basis Accidents and Severe Accidents. The Code Review Report, NK38-REP-03680-10109, declared a Gap because a Severe Accident Management Guidelines program has not been fully implemented at DNGS.

Gap 01463 was declared against Clause 7.8 of CNSC RD-337 which requires that equipment credited to operate during Beyond Design Basis Accident and severe accident states is assessed for its capacity to perform its intended function under the expected environmental conditions. A justifiable extrapolation of equipment behaviour may be used to provide assurance of operability, and is typically based on design specifications, environmental qualification testing, or other considerations. The Code Review Report, NK38-REP-0368010109, found that OPG has provisions in place to qualify equipment, however, a Gap was declared because a Severe Accident Management Guidelines program has not been fully implemented at DNGS.

Gap 01464 was declared against Clause 7.9.1 of CNSC RD-337 which requires that the design includes provision of instrumentation to monitor plant variables and systems over the respective ranges for normal operation, Anticipated Operational Occurrences, Design Basis Accidents, and Beyond Design Basis Accidents, in order to ensure that adequate information can be obtained on plant status. The Code Review Report, NK38-REP-03680-10109, found that DNGS complies for Anticipated Operational Occurrences and Design Basis Accidents, however, a Gap was declared because a Severe Accident Management Guidelines program has not been fully implemented at DNGS.

Gap 01465 was declared against Clause 7.9.3 of CNSC RD-337 which requires that instrumentation and recording equipment is such that essential information is available to support plant procedures during and following accidents by facilitating decisions in accident management. The Code Review Report, NK38-REP-03680-10109, found that it is expected that the existing Post Accident Radiation Monitoring instrumentation will provide substantial monitoring capability following any severe accident, thereby enabling suitable emergency response actions to be taken. However, a Gap was declared because a Severe Accident Management Guidelines program has not been fully implemented at DNGS.

Gap 01479 was declared against Clause 8.6.8 of CNSC RD-337 which requires consideration of pressure differentials and control of hydrogen in the design of containment internal structures. The Code Review Report, NK38-REP-03680-10109, found that these issues have been considered to some extent, however, a Gap was declared because a Severe Accident Management Guidelines program has not been fully implemented at DNGS.

Gap 01482 was declared against Clause 8.6.12 of CNSC RD-337 which requires consideration of the ability of the containment system to withstand loads associated with Severe Accidents as part of the design. The Code Review Report, NK38-REP-

03680-10109, found that the current design meets some of these requirements, however, a Gap was declared because a Severe Accident Management Guidelines program has not been fully implemented at DNGS.

As discussed for the Pickering B ISR IAEA NS-R-1 review above, all issues relating to SA and SAMG program have been closed per [B.24-13]. Also, refer to the PSR2 code review for CNSC REGDOC-2.3.2, which concludes that all gaps relating to the above clauses have been addressed.

D070 Consideration of Decommissioning During Design Phase

Clause 5.68 of IAEA NS-R-1, "Safety of Nuclear Power Plants: Design" requires that at the design stage, special consideration shall be given to the incorporation of features that will facilitate decommissioning and dismantling of the plant. Special attention should be paid to the choice of materials to minimize radioactive waste, access capabilities that may be necessary, and radioactive storage facilities. Gap 00781 identified that during original design phase of DNGS, no special consideration was given to decommissioning of the nuclear power plant.

Clause 7.24 of CNSC RD-337, "Design of New Nuclear Power Plants" mirrors the above requirement. It states that the future decommissioning and dismantling activities shall be taken into account, such that:

1. Materials are selected for the construction and fabrication of the plant components and structures with the intent of minimizing quantities of radioactive waste and assisting decontamination.

2. Plant layout is designed to facilitate access for decommissioning or dismantling activities; and 3. Consideration is given to the future potential requirements for storage of radioactive waste generated as a result of new facilities being built, or existing facilities being expanded.

Gap 01476 identified that during the design phase of DNGS no special consideration was given to the ultimate decommissioning and dismantling of the plant.

This issue was closed as an Acceptable Deviation in the final ISR report [B.24-24], and given there is a low safety impact, this is not a PSR2 gap.

D071 Coatings and Coverings

The gaps in this Issue are as follows:

Clause 6.67 in IAEA NS-R-1 requires the coverings and coatings for components and structures within the containment system shall be carefully selected, and their methods of application specified, to ensure fulfillment of their safety functions and to minimize interference with other safety functions in the event of deterioration of coverings and coatings. Gap 00795 identified that the OPG design specification does not meet all of these requirements.

Clause 8.6.11 of CNSC RD-337 requires that the coverings and coatings for components and structures within the containment system shall be carefully selected, and their methods of application specified, to ensure fulfillment of their safety functions and to minimize post-accident interference with other safety functions or accident mitigation systems. In addition, the choice of materials inside containment should take into account the impact of post-accident containment conditions that may affect containment performance and integrity and fission product release.

Gap 01481 states that there is no evidence that documents L-970, "Darlington GS A Sealing and Painting Specifications" and NK38-DM-21200 R001 "Reactor Building Internal Structure" considered the impact of post-accident containment conditions.

This issue has been closed as an Acceptable Deviation in the final ISR report [B.24-24] with the justification provided therein, noting that no further action is required. In addition, this issue was classified as an Acceptable Deviation for the Pickering B ISR, with supporting rationale provided. The rationale provided was equally applicable to Pickering Units 1,4. Hence, this issue does not result in a PSR2 gap for Pickering.

D072 Single Failure Criterion

Gap 01462 was declared against Clause 7.6.2 of CNSC RD-337 which contains various high level requirements for the single failure criterion. The Code Review Report, NK38-REP-03680-10109 [B.24-21], found that there are some instances of single failure vulnerabilities in systems other than the Special Safety Systems which have not been addressed.

This issue was classified as an Acceptable Deviation for the Pickering B IAEA NS-R-1 review as identified above. No incremental issues have been identified for the Darlington code reviews that would invalidate the rational for the Acceptable Deviation classification at Pickering B. The rationale provided for the Acceptable Deviation classification is also applicable to Pickering Units 1,4, hence, this does not represent a PSR2 gap.

D143 Severe Accident and Beyond Design Basis Accident (BDBA) Program/ SAMG

This issue is included with issue D068 above. No PSR2 gap has been identified.

D279 Cabling between Main Control Room and Secondary Control Area

This ISR Issue is made up of 2 ISR Gaps from NK38-REP-03680-10109, "Review of RD-337 Design of New Nuclear Power Plants for Darlington Integrated Safety Review".

Clause 8.10.1 of CNSC RD-337, "Design of New Nuclear Power Plants", requires that cabling for the instrumentation and control equipment in the Main Control Room is arranged such that a fire in the Secondary Control Room cannot disable the equipment in the Main Control Room. Gap # 01484 identifies that there are gaps with the requirements of CAN/CSA-N293-07, "Fire Protection for CANDU Nuclear Power Plants".

Clause 8.10.2 of CNSC RD-337 requires that cabling for the instrumentation and control equipment in the Secondary Control Room is arranged such that a fire in the Main Control Room cannot disable the equipment in the Secondary Control Room.

Gap # 01485 identifies that there are gaps with the requirements of CAN/CSA-N293-07.

Issue D279 [B.24-29] relating to RD-337 Clause 8.10.1 and 8.10.2 was subsequently moved to Issue D430 [B.24-30]. The issue at Darlington was due to a postulated fire event in the Common Secondary Control Area (CSCA) in which it was conservatively assumed that control of Group 2 systems, including Containment was lost. These gaps have subsequently been closed with the CNSC's acceptance of the Darlington Fire Hazard Assessment (FHA) and Fire Safe Shutdown Analysis (FSSA) as noted in [B.24-30].

At Pickering 5-8, the same fire event is not applicable as there is no CSCA and Group 2 systems are not used for process control during normal operation. Pickering 5-8 does have Unit Emergency Control Centers (UECC) in each Unit. In accordance with [B.24-31], Pickering 5-8 is designed such that all outputs from active safety systems to the control room are suitably buffered such that wires can be open or short circuited without disabling protective functions or causing common mode failures. Additionally, per the Pickering 5-8 FHA [B.24-32] and FSSA [B.24-33]), there is no impact on control of Containment (or any other safety systems) that prevents safe shutdown for a fire event in either the Main Control Room (MCR) or UECCs. Pickering 1,4 has remote monitoring and reactor trip capability in the Shutdown System Enhancement (SDSE) Instrument Rooms. These rooms are remote from the MCR and instrumentation and equipment is physically isolated from the MCR.

Therefore, neither of the gaps identified above are applicable to Pickering.

D276 Fire Protection

All gaps relating to fire protection were closed in the RD-337 review, noting that any issue will be addressed in CSA N293 and fire code reviews. The PSR2 CSA N293-12 [B.24-34] review is being addressed separately, and therefore is not repeated here.

<u>Additional RD-337 Gaps</u>

There were four additional gaps relating to CNSC RD-337 compliance that were either closed with a rationale or reclassified as acceptable deviations. These are:

- Clause 8.2.2 Accommodation of Primary Heat Transport (PHT) shrinkage for multi-unit shutdown (D277) [B.24-35]. This is not an issue for Pickering, as there are no credits for non-unit D_2O identified per the Pickering Units 1,4 and Pickering Units 5-8 Heat Transport System (HTS) Operational Safety Requirements (OSRs) [B.24-36] and [B.24-37]. Hence, this is not a PSR2 gap.

- Clause 8.3.3 Turbine Orientation (Issue D278) [B.24-38] was closed for Darlington noting that Turbine Failures were analyzed in the Safety Report and Dose Class limits were met. Turbine Failures at Pickering are addressed in the PSA Hazard Screening addressed in the PSR2 Hazard Analysis Safety Factor report
  The D278 issue resolution is also applicable to Pickering. Hence, this is not a PSR2 gap.

- Clause 8.8 and 8.112 Fire Water / Emergency Heat Removal System (EHRS) Interconnection (Issue D225) [B.24-39]. This is not an issue for Pickering. Pickering Units 5-8 has an Emergency Water Supply (EWS) supply to the HTS. Pickering Units 1,4 has a manual flowpath (33350-V478) that supplies to the HTS from firewater or Emergency Mitigating Equipment (EME) water. The gap was also related to fire coincident with LOCA relying on a common Emergency Service Water System. This is not an issue for Pickering where fire water is supplied by Diesel pumps (Pickering Units 1,4) or High Pressure Service Water (Pickering Units 5-8). Hence, this is not a PSR2 gap.

- Clause 8.11.2 relates to the Off-Gas System not being in-service (Issue D280) [B.24-40]. The D280 issue resolution applies equally to Pickering where the Off-Gas Management System is no longer in use [B.24-41]. Hence, this is not a PSR2 gap.

In summary, the above assessment has reviewed all Darlington PSR1 RD-337 gaps and issues and considered their applicability to Pickering PSR2. Additionally, all gaps and issues resulting from the Darlington PSR1 IAEA NS-R-1 review have been included in and addressed in the RD-337 issue discussions above.

B.24.2.2 Application of Post PSR1 Reviews

Per the preface of REGDOC-2.5.2, this document is primarily designed for new nuclear facilities,

> …*For existing facilities: The requirements contained in this document do not apply unless they have been included, in whole or in part, in the licensing basis.*

Per [B.24-42], OPG and the nuclear industry systematically reviewed the REGDOC-2.5.2 (draft) and provided comments. Many of the comments related to clarity and application. Notwithstanding the above, the approach for this review is to assume all clauses to be applicable to the existing plant and to assess compliance even if the clause may not actually be applicable or practicable for a mature nuclear power plant.

The table below details the additional incremental review of REGDOC-2.5.2 for Pickering. It identifies new additions or significant changes from RD-337 that have been introduced in REGDOC-2.5.2. In addition, clauses that were RD-337 gaps for Darlington and are considered applicable are included with the corresponding REGDOC-2.5.2 clause and the Gap is addressed in the context of Pickering PSR2.

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
1. Purpose	No requirements	n/a
2. Scope	No requirements	n/a
3. Relevant Legislation Clause identifies high level nuclear regulatory framework and establishes the Nuclear Safety and Control Act (NSCA) requirements.	A compliance assessment for Pickering PSR2 has been performed per [B.24-9] and demonstrates that Pickering is compliant.	**Compliant**

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
4. Safety Objectives and Concepts	Heading	n/a
4.1 General Nuclear Safety Objectives High level radiological protection, nuclear safety and environmental objectives.	No explicit requirements	n/a
4.2 Application of Technical Safety Objectives	Heading	n/a
4.2.1 Dose acceptance criteria *The committed whole-body dose for average members of the critical groups who are most at risk, at or beyond the site boundary, shall be calculated in the deterministic safety analysis for a period of 30 days after the analyzed event.* *This dose shall be less than or equal to the dose acceptance criteria of:* *1. 0.5 millisievert (mSv) for any AOO or* *2. 20 mSv for any DBA*	Clause 4.2.1 had a gap and Issue in the DSA review for Darlington RD-337 review [B.24-21]. OPG has a plan for the implementation of REGDOC-2.4.1 Deterministic Safety Analysis for Pickering. REGDOC-2.4.1 has the same requirements for AOO analysis and dose limits and OPG will address these as part of the compliance framework. However, for a new plant, demonstration that the requirements are met is mandatory. Therefore, this is a PSR2 gap relating to new plant requirements.	**PSR2 REGDOC-2.5.2 Gap #1** (Deterministic Safety Analysis) Safety Factor 5 (Deterministic Safety Analysis)
4.2.2 Safety goals … two qualitative safety goals have been established: *Individual members of the public* *Societal risks* *Core damage frequency* *10^{-5} per reactor year.* *Small release frequency* *a release to the environment of more than 10^{15} becquerels of iodine-131 shall be less than 10^{-5} per reactor year. A greater release may require temporary evacuation of the local population.* *Large release frequency* *a release to the environment of more than 10^{14} becquerels of cesium-137 shall be less than 10^{-6} per reactor year. A greater release may require long term relocation of the local population…*	This clause requires that all event frequencies should be summed and core damage frequency be $<10^{-5}$ yrs/yr. This is a limit as opposed to a goal. The OPG governance uses 10^{-4} yrs/yr as the Safety Goal [B.24-43]. Therefore, this is a PSR2 gap relating to new plant requirements.	**PSR2 REGDOC-2.5.2 Gap #2** (Probabilistic Safety Assessment) Safety Factor 6 (Probabilistic Safety Analysis)
4.2.3 Safety Analysis *To demonstrate achievement of the safety objectives, a comprehensive hazard analysis (HA), a deterministic safety analysis (DSA), and a*	These are high level objectives. Reviews of DSA, PSA and HA are being addressed as part of the Safety Factor reviews for PSR2 under	Addressed in other PSR2 Safety Factor and code reviews.

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
probabilistic safety assessment (PSA) are carried out. These analyses identify all sources of exposure, in order to evaluate potential radiation doses to workers at the plant and to the public, and to evaluate potential effects on the environment. The safety analyses examine plant performance for: *1. Normal operation;* *2. Anticipated operational occurrences;* *3. Design basis accidents; and* *4. Beyond design basis accidents (BDBAs), including event sequences that may lead to a severe accident.*	Safety Factors 5, 6 and 7 respectively. A PSR2 review of REGDOC-2.4.1, "Deterministic Safety Analysis" [B.24-14] is being performed. A PSR2 review of REGDOC 2.4.2, "Probabilistic Safety Assessment (PSA) for Nuclear Power Plants" [B.24-15] is being performed. Hence, these objectives are not addressed in this review.	PSR2 REGDOC-2.4.1 Gap PSR2 REGDOC-2.4.2 Gap
4.2.4 Accident Mitigation and Management *The design shall include provisions to limit radiation exposure in normal operation and AOOs to ALARA [As Low As Reasonably Achievable] levels, and to minimize the likelihood of an accident that could lead to the loss of normal control of the source of radiation. However, given that there is a remaining probability that an accident may occur, measures shall be taken to mitigate the radiological consequences of accidents….*	The high level objectives in this clause are explicitly addressed in a separate review of the requirements for accident management. This review has been performed as part of the PSR2 review of REGDOC-2.3.2, "Accident Management" [B.24-44].	**Compliant** Addressed in other PSR2 code reviews.
4.3 Safety concepts *This section details the high level objectives relating to Defence in depth and establishes the five levels of defence in depth and that they shall be independent to the extent practicable. Physical barriers between the layers of defence. Operational limits and conditions, to clearly establish the limits of the different levels and finally they enforce the Interface of safety with security and safeguards.*	Defence in depth is embodied in "Nuclear Management System", N-CHAR-AS-0002, [B.24-45]. Defense in Depth is partially addressed in PSR2 Plant Design Safety Factor 1 Report, under Review Task 4. The 'Procedures' Safety Factor 11 review addresses the operational procedures for the first two levels of Defense in depth. Operational limits and conditions are addressed in the PSR2 Safe Operating Envelope (SOE) review, CSA Standard N290.15-10 (R2015), "Requirements for the Safe Operating Envelope of Nuclear Power Plants" [B.24-46]. Levels 3, 4 and 5 of Defense in depth are addressed in PSR2 code reviews of REGDOC-2.3.2, "Accident Management" [B.24-44] and REGDOC-2.10.1, "Nuclear Emergency	**Compliant** Addressed in other PSR2 Safety Factor and code reviews.

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	Preparedness and Response" [B.24-47]. In addition, an integrated assessment of 'defense-in-depth' will be done as part of the Global Assessment per [B.24-9]. Security and safeguards are not in the PSR2 scope.	
5. Safety Management in Design This section details the role of the Design Authority, design process management, quality assurance and use of Operating Experience and research.	The PSR2 review for Safety Factor 10 Report "Organization, Management System, and Safety Culture", addresses the concepts and requirements in this clause. Additionally, a separate PSR2 review of OPEX has been performed as part of PSR2 Safety Factor 9, "Use of Experience from Other Nuclear Power Plants and Research Findings". OPG Nuclear Program, N-PROG-MP-0007 [B.24-48], "Conduct of Engineering", implements a series of programs, standards, and procedures for performing engineering in a consistent manner across OPG Nuclear. The Design Authority roles and responsibilities reside with the Chief Nuclear Engineer (CNE), who prescribes (1) the overall requirements for the Conduct of Engineering program, (2) the scope, development, and implementation of Engineering programs, and (3) the manner in which design activities are performed. The CNE may delegate, within specified limits and controls, station specific Engineering and Design Authority responsibilities as detailed in, "Engineering and Design Authority" [B.24-49]. In addition, the overall design program is addressed in the review of CSA N286, "Management System Requirements for Nuclear Power Plants", [B.24-50], which has been performed as part of PSR2.	**Compliant** Addressed in other PSR2 Safety Factor and code reviews.

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
6. Safety Requirements	Heading	n/a
6.1 Application of Defence in Depth *The design of an NPP shall incorporate defence in depth. The levels of defence in depth shall be independent to the extent practicable. Defence in depth shall be achieved at the design phase through the application of design provisions specific to the five levels of defence.* This section provides more detail regarding the five layers of defence in depth.	This clause is unchanged from that in RD-337 addressed in the Darlington PSR1 review [B.24-21]. That review is generic to OPG Nuclear and is fully applicable to Pickering. As noted in Clause 4.3 above, Defense in depth is partially addressed in PSR2 Plant Design Safety Factor 1 Report, under Review Task 4. In addition, an integrated assessment of 'Defense-in-depth' will be done as part of the Global Assessment per [B.24-9].	**Compliant**
6.2 Safety Functions *The NPP design shall provide adequate means to:* *1. maintain the plant in a normal operational state* *2. ensure the proper short-term response immediately following a PIE* *3. facilitate the management of the plant in and following DBAs and DECs [Design Extension Conditions].* …	Normal operation of the plant is within the envelope established in the Operating Manuals. This is addressed in the "Procedures" Safety Factor 11, Review Task #6: "Procedures for Normal, Abnormal and Emergency Conditions" review. The Operating Policies and Principles [B.24-51] and [B.24-52], in conjunction with the SOE establish the operating envelope within the Safety Analysis. The Pickering 1,4 [B.24-56] and 5-8 [B.24-57], Safety Reports – Part 3, identify the response of the plant to PIEs. The systems and equipment required to ensure the plant remains within it analyzed envelope are included in the Safety Related System lists [B.24-58]. The importance of the specific systems is addressed in PSR2 Plant Design Safety Factor 1 Report, under Review Task 3, "List of SSCs Important to Safety". The safety functions for dealing with DECs are addressed in the beyond design basis accident management program [B.24-59].	**Compliant**

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	The guidelines for managing mitigating systems and equipment for BDBA events are documented in [B.24-60] and [B.24-61]. Pickering is compliant with this clause.	
3.3 Accident Prevention and Plant Safety Characteristics The design shall apply the principles of defence in depth to minimize sensitivity to PIEs. Following a PIE, the plant is rendered safe by: 1. inherent safety features 2. passive safety features 3. specified procedural actions 4. action of control systems 5. action of safety systems 6. action of complementary design features (CDFs)	This clause is unchanged from that in RD-337 addressed in the Darlington PSR1 review [B.24-21], with the exception of the sixth item relating to CDFs, which is new. The Darlington review is generic and fully applicable to Pickering. The addition relating to the CDFs is addressed in the PSR2 review relating to REGDOC-2.3.2 "Accident Management" [B.24-44]. Pickering is compliant with this clause.	**Compliant**
6.4 Radiation protection and acceptance criteria *The design shall include provisions for the prevention and mitigation of radiation exposures resulting from DBAs and DECs.* *The design shall also ensure that potential radiation doses to the public from AOOs and DBAs do not exceed dose acceptance criteria provided in section 4.2.1. The calculated overall risk to the public shall meet the safety goals in section 4.2.2.*	Clause 6.4 was a gap and Issue for DSA for Darlington RD-337 review [B.24-21]. See 4.2.1 for discussion above. Compliance with AOO dose limits will be addressed through the REGDOC-2.4.1 compliance framework.	**PSR2 REGDOC-2.5.2 Gap #1** (Deterministic Safety Analysis) Safety Factor 5 (Deterministic Safety Analysis)
6.5 Exclusion Zone *The design shall include adequate provision for an appropriate exclusion zone. The appropriateness of the exclusion zone shall be based on several factors, including:* *1. evacuation needs* *2. land usage needs* *3. security requirements* *4. environmental factors*	The exclusion zone and requirements for maintaining it are identified in the LCH, Section 1.4 [B.24-3]. Section 10 of [B.24-3] explicitly addresses Pickering's requirements in the areas of environmental monitoring and controls. This also addresses land use within the exclusion zone. Evacuation requirements are identified in the Consolidated Nuclear Emergency Plan [B.24-62]. Pickering is compliant with this clause.	**Compliant**

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
6.6 Facility layout *The facility layout shall take into account PIEs to enhance protection of SSCs important to safety.* *The design shall take into account the interfaces between the safety, security and safeguards provisions of the NPP and other aspects of the facility layout, such as:* …	This clause details security provision requirements and the interface with safety-related systems and structures. Security and Safeguards are not included in this scope of this review.	n/a
6.6.1 Requirements for multiple units *The design shall take due account of challenges to multiple units at a site. Specifically, the risk associated with common-cause events affecting more than one unit at a time shall be considered.*	This is a new clause that was not previously included in RD-337. The requirements in this clause have been addressed in the REGDOC-2.3.2, "Accident Management" [B.24-44] PSR2 review. Pickering is compliant with this clause.	**Compliant** Addressed in other PSR2 code review.
4. General Design Requirements	Heading	n/a
7.1 Safety classification of structures, systems and components *The design authority shall classify SSCs using a consistent and clearly defined classification method. The SSCs shall then be designed, constructed, and maintained such that their quality and reliability is commensurate with this classification.* *In addition, all SSCs shall be identified as either important or not important to safety. The criterion for determining safety importance is based on:* *1. safety function(s) to be performed* *2. consequence(s) of failure* *3. probability that the SSC will be called upon to perform the safety function* *4. the time following a PIE at which the SSC will be called upon to operate, and the expected duration of that operation.* *SSCs important to safety shall include:* *1. safety systems* *2. complementary design features* *3. safety support systems* *4. other SSCs whose failure may lead to safety concerns (e.g., process and control systems)* *Appropriately designed interfaces shall be provided between SSCs of different classes in order to minimize the risk of having SSCs less important to*	This clause was compliant for the Darlington RD-337 review. Pickering uses the same approach to classification as Darlington and is also compliant. However, the introduction of Design Extension Conditions (DEC) and Complementary Design Features (CDFs) in this clause is a new requirement. The systems and equipment required to ensure the plant remains within its analyzed envelope are included in the Safety Related System lists [B.24-58] and those credited in the Safety Report are addressed in the SOE [B.24-63]. The importance of the specific systems is addressed in PSR2 Plant Design Safety Factor 1 Report, under Review Task 3, "List of SSCs Important to Safety". The safety functions for dealing with DECs are addressed in the beyond design basis accident management program [B.24-59]. The guidelines for managing mitigating systems and equipment for BDBA events are	**Compliant** Addressed in other PSR2 Safety Factor review.

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
safety adversely affecting the function or reliability of SSCs of greater importance….	documented in [B.24-60] and [B.24-61]. Pickering is compliant and has established provisions for DECs and CDFs [B.24-64].	
7.2 Plant design envelope *The design authority shall establish the plant design envelope, which comprises all plant states considered in the design: normal operation, AOOs, DBAs and DECs, as shown in figure 1.*	DECs are a new concept being introduced. However, both BDBA and DECs have been addressed for Pickering as detailed in Clause 7.1 immediately above.	**Compliant**
7.3 Plant states The plant states are grouped into four states: 1) Normal Operation 2) Anticipated Operational Occurances 3) Design Basis Accidents 4) Design Extension Conditions, including Severe Accidents Items 1 and 3 are addressed here , while Items 2 and 4 have incremental new requirements relevant to Pickering that merit further discussion below:	Normal operation of the plant is within the envelope established in the Operating Manuals. This is addressed in the "Procedures" Safety Factor 11, Review Task #6: "Procedures for Normal, Abnormal and Emergency Conditions" review. The Operating Policies and Principles [B.24-51] and [B.24-52], in conjunction with the SOE [B.24-63], establish the operating envelope within the Safety Analysis for Design Basis Accidents. DECs, as a subset of BDBAs, are a new concept being introduced in item 4. This new addition and the remainder of the clause is addressed in Clause 7.3.4 below.	**Compliant**
7.3.2 Anticipated operational occurrences *The design shall include provisions such that releases to the public following an AOO do not exceed the dose acceptance criterion provided in section 4.2.1.* *The design shall also provide that, to the extent practicable, SSCs not involved in the initiation of an AOO shall remain operable following the AOO.* *The response of the plant to a wide range of AOOs shall allow safe operation or shutdown, if necessary, without the need to invoke provisions beyond Level 1 defence in depth or, at most, Level 2.* *…*	This was clause 7.3.2 for the RD-337 review and was a gap for DSA for RD-337 [B.24-21] at Darlington. As identified above (under 4.2.1 above), this is a PSR2 Gap relating to AOOs.	**PSR2 REGDOC-2.5.2 Gap #1** (Deterministic Safety Analysis) Safety Factor 5 (Deterministic Safety Analysis)

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
7.3.4 Design extension conditions *The design authority shall identify the set of design-extension conditions (DECs) based on deterministic and probabilistic methods, operational experience, engineering judgment and the results of research and analysis. These DECs shall be used to further improve the safety of the NPP by enhancing the plant's capabilities to withstand, without significant radiological releases, accidents that are either more severe than DBAs or that involve additional failures…*	DECs is new concept that was not in RD-337. The Fukushima Action Item (FAI) process has addressed this concept per [B.24-13] and [B.24-53], for Pickering. A Standard and Guidelines have been established for BDBA program management [B.24-59] and [B.24-65]. Complementary Design Feature (CDF) design, management and surveillance [B.24-64], [B.24-60], [B.24-61] have been established. Equipment Important to Emergency Response (EITER) is managed through a new managed process [B.24-67]. Pickering is compliant with this requirement.	**Compliant**
7.3.4.1 Severe accidents within design extension conditions *The design shall be balanced such that no particular design feature or event makes a dominant contribution to the frequency of severe accidents, taking uncertainties into account. Early in the design process, the various potential barriers to core or fuel degradation shall be identified, and features that can be incorporated to halt core or fuel degradation at those barriers shall be provided.* *The design shall also identify the equipment to be used in the management of severe accidents including equipment that is available onsite and offsite…* *For DECs with severe core damage, the containment shall maintain its role as a leak-tight barrier for a period that allows sufficient time for the implementation of offsite emergency procedures following the onset of core damage. Containment shall also prevent uncontrolled releases of radioactivity after this period…* *Consideration shall be given to the prevention of recriticality following severe accidents.*	The SAMG program is addressed under the BDBA management standard [B.24-59]. All of the identified issues relating to BDBA mitigation equipment (EME) and procedures have been addressed. The design of the BDBA and SAMG response has addressed these issues. The requirement for containment to maintain a leak tight barrier for a period of time was not an explicit requirement in BDBA/SA mitigation. This represents a PSR2 Gap. A combination of multi-unit safety analysis and implementation of additional mitigating provisions to support containment integrity for RLCs (e.g., enhancements such as Phase 2 EME) are expected to address this gap. However, this is identified as a PSR2 gap specific to Containment leak tightness. Consideration of criticality is addressed in SAMG, specifically relating to any strategies that add	**PSR2 REGDOC-2.5.2 Gap #3** (Containment Leak Tightness for DECs) Safety Factor 1 (Plant Design)

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	D_2O (See SAG2 for constraints) to the reactor. There is no PSR2 gap.	
7.4 Postulated Initiating Events (PIEs) The requirements for systematic identification and classification of PIEs are identified. REGDOC-2.4.1 (DSA) and REGDOC-2.4.2 (PSA) are to be used to identify the PIEs. The events should include: 1) Internal events 2) External events 3) Combination of events Items 2 and 3 have incremental new requirements relevant to Pickering that merit further discussion below:	The internal events are identified in the Pickering Safety Reports [B.24-54] and [B.24-55]. Additionally, identification and quantification of PIEs in the PSAs are performed in accordance with Reference [B.24-69]. The PIEs for Pickering 1,4 are included in Reference [B.24-70], while those for Pickering 5-8 are included in [B.24-71].	**Compliant**
7.4.2 External hazards *All natural and human-induced external hazards that may be linked with significant radiological risk shall be identified. External hazards which the plant is designed to withstand shall be selected, and classified as DBAs or DECs…*	Clause 7.4.2 was a gap and Issue in DSA for RD-337 for Darlington [B.24-21]. However, hazard screening has now been conducted as part of the Pickering PSA program. This is addressed in the PSR2 Hazard Analysis Safety Factor report. The hazard screening and identification for Pickering 1,4 is included in Reference [B.24-72] while that for Pickering 5-8 is in [B.24-73]. Therefore, this is not a PSR2 gap.	**Compliant**
7.4.3 Combination of events *Combinations of randomly occurring individual events that could credibly lead to AOOs, DBAs, or DECs shall be considered in the design. Such combinations shall be identified early in the design phase, and shall be confirmed using a systematic approach.* *Events that may result from other events, such as a flood following an earthquake, shall be considered to be part of the original PIE.*	This was clause 7.4.3 in RD-337 and was a gap for DSA [B.24-21] for Darlington. The review identified that not all initial states or initiating events were considered. The PSAs already consider combinations of events. Similarly, the Hazard Screening assessments have considered combinations. The DSA in the Safety Report assumes random failure of select mitigating functions. Notwithstanding, as noted for the Darlington RD-337 review, there remains a gap relating to identification and treatment of event combinations. This is a PSR2 gap, however, it is already captured within the scope of the REGDOC-2.4.1 review and gap.	Addressed in other PSR2 code review. PSR2 REGDOC-2.4.1 Gap

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
7.5 Design rules and limits *The design authority shall specify the engineering design rules for all SSCs. These rules shall comply with appropriate accepted engineering practices…* *The design of complementary design features should be such that they are effective for fulfilling the actions credited in the safety analysis, with a reasonable degree of confidence. Other SSCs that are credited for DECs should also meet this expectation.*	The design rules are governed by the "Design Management' [B.24-74] and the "Engineering Change Control" (ECC) [B.24-75] programs. These programs ensure designs rules and accepted engineering practices are adhered to. Rules for DECs are new requirements that were not in RD-337. However, they have been established and are addressed fully in ECC and specific governance and guidance [B.24-59] and [B.24-64].	**Compliant**
7.6 Design for Reliability *All SSCs important to safety shall be designed with sufficient quality and reliability to meet the design limits. A reliability analysis shall be performed for each of these SSCs. Where possible, the design shall provide for testing to demonstrate that the reliability requirements will be met during operation. The safety systems and their support systems shall be designed to ensure that the probability of a safety system failure on demand from all causes is lower than 10^{-3}.* …	The failure probability of 10^{-3} in the REGDOC-2.5.2 context applies to on-demand failure of a 'safety system' which is synonymous with a SIS per the REGDOC-2.5.2 definition. The target reliabilities/unavailabilities for the Systems Important to Safety (SIS) are included in Table 2.1-1 of the 2015 Annual Reliability Report [B.24-76]. For the Special Safety Systems, all Pickering 1,4 and Pickering 5-8 systems meet the target, with exception of Pickering 1,4 ECI, which has a target of $2x10^{-3}$ yrs/yr. This is compliant with the RD/RG-98 for an existing plant, however, it is greater than the requirement for a new plant. In addition, the other SIS standby safety support and safety-related support systems generally do not meet the on-demand reliability requirement for a new plant. This is therefore a PSR2 gap.	**PSR2 REGDOC-2.5.2 Gap #4** (On-Demand Reliability of Safety Systems) Safety Factor 1 (Plant Design)
7.6.1 Common-cause failures *The potential for common-cause failures (CCFs) of items important to safety shall be considered in determining where to apply the principles of separation, diversity and independence so as to achieve the necessary reliability. Such failures could simultaneously affect a number of different items important to safety. The event or cause could be a design deficiency, a manufacturing deficiency, an operating or maintenance error, a natural phenomenon, a human-induced event, or an*	Clause 7.6.1 was a gap for RD-337 [B.24-21] in the Darlington review. For Darlington, this issue was addressed under the Darlington A Risk Assessment (DARA) update program. Similarly, for Pickering, the PSA update has included and addressed CCFs. Pickering is compliant with this requirement.	**Compliant**

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
unintended cascading effect from any other operation or failure within the plant.		
7.6.2 Single-failure criterion *All safety groups shall function in the presence of a single failure. The single-failure criterion requires that each safety group can perform all safety functions required for a PIE in the presence of any single component failure, as well as:* *1. all failures caused by that single failure* *2. all identifiable but non-detectable failures, including those in the non-tested components* *3. all failures and spurious system actions that cause (or are caused by) the PIE…*	Clause 7.6.2 was a gap for RD-337 [B.24-21] for Darlington. However, it was classified as an Acceptable Deviation with the rationale provided as detailed in Section B.24.2.1 of this PSR2 assessment, above. This clause was also an IAEA NS-R-1 gap and Acceptable Deviation for Pickering 5-8 in PSR1. The rationale provided for classifying this requirement as an Acceptable Deviation for Pickering 5-8 is also applicable to Pickering 1,4. Pickering is compliant with this requirement.	**Compliant**
7.6.3 Fail-safe Design *The concept of fail-safe design shall be incorporated, as appropriate, into the design of systems and components important to safety.*	This is a general principle and good design practice that has been incorporated into the design of systems and components important to safety as part of design, to the extent practicable. Failure positions and states (e.g., open, close, as-is, de-energized, etc.) of components due to loss of power, control and/or air for SIS are generally documented in the Auxiliary Service Failures (Section 8) of the Operating Manuals, e.g., reference [B.24-77]. Where fail-safe cannot be achieved or unsafe failures occur, annunciations are provided so that the failure can be readily detected and corrected. Pickering is compliant with this requirement.	**Compliant**
7.6.4 Allowance for equipment outages *The design shall include provisions for adequate redundancy, reliability, and effectiveness, to allow for online maintenance and online testing of systems important to safety.*	There is an extensive set of on-line testing and maintenance/surveillance predefines for Safety Systems. These are identified in the SOE Compliance Tables in accordance with [B.24-63] and in the system reliability models as identified in Appendix F of the annual reliability report [B.24-76]. Credited testing is identified in Appendix G of [B.24-76].	**Compliant**

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	This demonstrates that the designs include adequate provisions for surveillance and Pickering is compliant with these requirements.	
7.6.5 Shared Systems This clause establishes the requirements relating to sharing of safety and process functions. There are also two sub-clauses relating to sharing Safety System instrumentation and the sharing of SSCs important to safety between reactors. Sharing of instrumentation is addressed here while sharing between units is addressed below.	There are several cases where sharing safety and process functions (including instrumentation) exists at both Pickering 1,4 and Pickering 5-8 (e.g., Boilers and Steam Reject Valves (SRVs), Moderator, Class III and II power, etc.). In all cases the safety function standards and rules apply and suitable isolation between the process control and safety functions is provided. Pickering is compliant with these requirements.	**Compliant**
7.6.5.2 Sharing of SSCs between reactors *SSCs important to safety shall typically not be shared between two or more reactors. In exceptional cases when SSCs are shared between two or more reactors, such sharing shall exclude safety systems and turbine generator buildings that contain high-pressure steam and feedwater systems, unless this contributes to enhanced safety. If sharing of SSCs between reactors is arranged, then the following requirements shall apply:* *1. safety requirements shall be met for all reactors during operational states, DBAs and DECs* *2. in the event of an accident involving one of the reactors, orderly shutdown, cool down, and removal of residual heat shall be achievable for the other reactor(s)…*	This sub-clause has a new requirement that sharing of safety systems and the turbine generator building not be permitted. ECI and Negative Pressure Containment are shared between units at Pickering. Additionally, the Turbine Buildings are shared between units on each station. If either common ECI or Containment are unavailable, all affected units are considered impaired and must shutdown within specified time limits, hence minimizing the risk of a coincidental DBA. Environmental conditions in the common turbine building have been assessed and credited provisions have been protected to ensure the ability to shutdown/control, cool and monitor remains available on non-accident units. Notwithstanding the above, sharing of safety systems and having a common turbine building for multiple units is a PSR2 gap.	**<u>PSR2 REGDOC-2.5.2 Gap #5</u>** (Sharing of Safety Systems and Turbine Hall) Safety Factor 1 (Plant Design)

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
7.7 Pressure-retaining structures, systems and components *All pressure-retaining SSCs shall be protected against overpressure conditions, and shall be classified, designed, fabricated, erected, inspected, and tested in accordance with established standards. For DECs, relief capacity shall be sufficient to provide reasonable confidence that pressure boundaries credited in severe accident management will not fail….* *Pressure-retaining components whose failure will affect nuclear safety shall be designed to permit inspection of their pressure boundaries throughout the design life…* In addition to the above, the guidance section of the clause provides additional considerations with regards to Leak-before-break system design.	The requirements for pressure retaining components and inspections are addressed in the CSA N285 series of code reviews as part of PSR2, included under the Plant Design Safety Factor 1 review. Inspection requirements and condition monitoring are addressed under Safety Factor 2 (Actual Conditions of SSCs) and Safety Factor 4 (Aging) codes and standards reviews [B.24-68]. Heat Transport System overpressure protection requirements for DECs has been addressed as part of the Fukushima Action Items, FAI 1.1.1 [B.24-53]. Further, boiler relief capacity for DECs is bounded by the relief capacity for DBAs initiating from high power. Pickering is compliant with this requirement.	**Compliant** Addressed in other PSR2 Safety Factor and code reviews.
7.8 Equipment environmental qualification *The design shall include an equipment environmental qualification (EQ) program. Development and implementation of this program shall ensure that the following functions can be carried out:* … *Equipment and instrumentation credited to operate during DECs shall be demonstrated, with reasonable confidence, to be capable of performing their intended safety function(s) under the expected environmental conditions. A justifiable extrapolation of equipment and instrumentation behaviour may be used to provide assurance of operability, and is typically based on design specifications, environmental qualification testing, or other considerations.*	This same issue was addressed in Clause 7.8 for the RD-337 [B.24-21] review for Darlington. A gap was identified relating to the absence of qualification for BDBA conditions. As discussed in Section B.24.2.1 for Darlington, Issues D072 and D143 have been closed for both Darlington and for Pickering as part of the FAI process [B.24-13]. The DBA qualification is addressed in a PSR2 code review for CSA N290.13 [B.24-66] included in [B.24-68]. In this clause, the BDBA term from RD-337 has been replaced by DEC, and AOOs have been added to the qualification requirements. However, all requirements in this clause have been addressed in the other code reviews. The qualification of equipment for DECs is specifically addressed in the PSR2 code review for REGDOC-2.3.2, "Accident Management" [B.24-44]. Pickering is compliant with this requirement.	**Compliant** Addressed in other PSR2 Safety Factor and code reviews.

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
7.9 Instrumentation and control **7.9.1 General** *The design shall include provision of instrumentation to monitor plant variables and systems over the respective ranges for operational states, DBAs and DECs, in order to ensure that adequate information can be obtained on plant status.* **...** *This shall include instrumentation for measuring variables that can affect the fission process, the integrity of the reactor core, the reactor cooling systems, and containment, as well as instrumentation for obtaining any plant information that is necessary for its reliable and safe operation…*	Sections 6 and 7 of Part 2 of the Pickering Safety Reports [B.24-54] and [B.24-55] provide a high level summary of instrumentation and control related to safety systems and process control. Further specific detail can be found in the USI 60000-series of Design Manuals. As part of PSR2 scope, three separate code reviews relating to instrumentation and control have been performed against the following: • CSA N290.1, "Requirements for Shutdown Systems of Nuclear Power Plants" [B.24-78] • CSA N290.4, "Reactor Control Systems of Nuclear Power Plants" [B.24-79] • CSA N290.6, "Requirements for Monitoring and Display of Nuclear Power Plant Safety Functions in the Event of an Accident" [B.24-80] The qualification of instrumentation for DECs is specifically addressed in the PSR2 code review for REGDOC-2.3.2, "Accident Management" [B.24-44]. There are no gaps for any of the above standards relating to instrumentation and control, and there are no PSR2 gaps.	**Compliant** Addressed in other PSR2 Safety Factor and code reviews.
7.9.2 Use of computer-based systems or equipment *Appropriate standards and practices for the development and testing of computer hardware and software shall be established and implemented throughout the lifetime of the system or equipment, and, in particular, throughout the software development cycle.* …	A separate PSR2 code review of CSA N290.14 (2015) [B.24-81], relating to qualification of hardware and software has been performed. The review found that new applications and changes comply with the standard. However, one gap was identified relating to absence of categorization and qualification for some legacy real-time process computing applications. This gap is also applicable to this clause. Hence, there is a Gap for PSR2.	Addressed in other PSR2 code review. PSR2 CSA N290.14-15 Gap

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
7.9.3 Accident monitoring instrumentation *Instrumentation and recording equipment shall be such that essential information is available to support plant procedures during and following DBAs and DECs…*	PSR2 review against CSA N290.6-09 [B.24-80] determined that Pickering is compliant with these requirements including BDBA conditions. Guidance under 7.9.3 identifies that instrumentation shall be available for measuring hydrogen concentration. This requirement is also a requirement for new plants in CSA N290.3-11 [B.24-111], Clauses 9.5.5 and 10.2.3. This issue was identified as being acceptably addressed given the implementation of PARs and improvements made to hydrogen concentration estimation in SAMG. Pickering is compliant for PSR2.	**Compliant**
7.10 Safety support system *The safety support systems shall ensure that the fundamental safety functions are available in operational states, DBAs and DECs. …* *2. support continuity of the fundamental safety functions until long-term (normal or backup) service is re-established:* *a. without the need for operator action to connect temporary onsite services for at least 8 hours.* *b. without the need for offsite services and support for at least 72 hours…* *Pre-installed equipment can be credited for accident mitigation after 30 minutes where only control room actions are needed or after 1 hour if field actions are needed. These actions should be limited to operating valves, starting pumps, etc....*	The 72 hours is consistent with the guidance for PSA and the BDBA requirements per [B.24-60] and [B.24-61]. For the DEC reference cases, where the Deaerator Storage Tank inventory remains available, the 8 hour requirement is satisfied [B.24-65]. Additionally, this clause introduces new requirements for times after which main control room and local field action may be credited of 30 minutes and 1 hour respectively. This is a change from Clause 8.10.4 of RD-337 which had the 15 and 30 minute requirements, hence DNGS was compliant. The Pickering Safety Reports [B.24-56] and [B.24-57] – Part 3 – Section 1 Integrated Summary, assess operator credits after 15 minutes for control room and 30 minutes for field actions. The Safety Analysis assumptions have a different perspective than these design requirements for a new plant. The current design requirements are established to provide ample margin to account for actual plant condition and experience. Whereas the action times in safety analysis generally assume that the relevant parameters, conditions and alarms are at a conservative limit. Additionally, for a mature plant,	**PSR2 REGDOC-2.5.2 Gap #6** (Allowable Times for Crediting On-Site Operator Actions) Safety Factor 1 (Plant Design)

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	there is significant operating experience (including drills and exercises) that provide assurance that the credited times can be achieved. Notwithstanding the above, the issues relating to on-site operator action times are a PSR2 gap.	
7.11 Guaranteed shutdown state (GSS) This clause identifies the high level requirements of a GSS.	GSS requirements for Pickering 1,4 and Pickering 5-8 are documented in the respective Moderator System Operational Safety Requirements [B.24-82] and [B.24-83] which, along with their associated Compliance Tables and implementing documents, satisfy all requirements. Pickering is compliant for PSR2.	**Compliant**
7.12 Fire safety *The design of the NPP, including that of external buildings and SSCs integral to plant operation, shall include provisions for fire safety.*	For Darlington, this clause was a gap for RD-337 [B.24-21]. The Darlington gaps were reviewed in B.24.2.1 above, and no specific gaps were identified as being applicable to Pickering. However, for PSR2, a separate code review is being performed for fire protection, CSA N293-12 [B.24-34]. Additionally, as specified in [B.24-9], code reviews are being performed for the: - Fire protection aspects of the 2010 version of the "National Building Code of Canada" (NBCC), - the 2010 version of "National Fire Code of Canada" (NFCC), - NFPA-20 (2016), "Standard for the Installation of Stationary Pumps for fire Protection" and, - NFPA-24 (2016), "Standard for the Installation of Private Fire Service Mains and their Appurtenances".	Addressed in other PSR2 code reviews. PSR2 CSA N293-12 Gap
7.13 Seismic qualification and design *The seismic qualification of all SSCs shall meet the requirements of Canadian national or equivalent standards...* **7.13.1 Seismic design and classification**	The guidance section of clause 7.13.1 has been added in REGDOC-2.5.2 and provides specific references to best-practices and industry guidance for seismic qualification. Additionally, the	**<u>PSR2 REGDOC-2.5.2 Gap #7</u>** (Seismic Qualification and Design)

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
A beyond-design-basis earthquake (BDBE) shall be identified that meets the requirements for identification of DECs as described in section 7.3.4. SSCs credited to function during and after a BDBE shall be demonstrated to be capable of performing their intended function under the expected conditions. Such demonstration shall provide high confidence of low probability of failure (HCLPF) under BDBE conditions for these SSCs. This demonstration need not be seismic qualification by testing. … *Seismic input motion, derived from the DBE, should be based on seismicity and geologic conditions at the site and expressed in such a manner that it can be applied for the qualification of SSCs. The DBE is defined by multiplying the mean site specific uniform hazard spectrum with a probability of occurrence of 10^{-4}/yr by a design factor, defined in the standard ASCE 43-05, Seismic Design Criteria for Structures, Systems and Components in Nuclear Facilities. The probability of occurrence of the defined DBE is therefore equivalent to the probability of DBAs.* *…..* ***Guidance*** *Any evaluation for BDBE should utilize the methodology in the Electrical Power Research Institute, (EPRI) TR-103959, Methodology for Developing Seismic Fragilities to determine if a HCLPF goal is met.* *…* *Beyond-design-basis margin should be such that seismically induced SSC failure probabilities do not contribute to the total core damage frequency and small and large release frequency to the extent that they do not meet the safety goals. To support meeting the safety goals, the acceptance criterion for BDBE should demonstrate that the plant HCLPF is at least 1.67 times the DBE.*	concept of qualification for DECs has been introduced. Per [B.24-9], the CSA N289 series of standards have been reviewed as part of PRS2 scope and the reviews are documented in [B.24-68]. These reviews did not identify any gaps relating to the requirements in this clause. Pickering 5-8 was originally designed to be seismically qualified as detailed in Section 2.2 of [B.24-55]. Pickering 1,4 was assessed for seismic qualification using Seismic Margin Assessment (SMA) methodology as documented in Part 2, Section 2.3 of [B.24-54] and in [B.24-84]. Subsequently Pickering 5-8 was also assessed using SMA, as part of the seismic PSA [B.24-85]. A seismic PSA has also been performed for Pickering 1,4 [B.24-86]. The SMAs address the DEC seismic event as detailed in [B.24-64]. The clause requires the DBE be defined by multiplying the mean Uniform Hazard Spectrum (UHS) with an occurrence of 10^{-4} occ/yr by a design factor. The SMAs both use a representative event, the Review Level Earthquake (RLE) which has a frequency commensurate with that for the DEC. For both stations, the RLE is defined as the 84th percentile Unified Hazard Response Spectrum (UHRS) with a return period of 10,000 years (i.e., 10^{-4} occ/yr), having a peak ground acceleration of 0.23g. Pickering 1,4 plant-limiting HCLPF is 0.23g as per [B.24-86]. The Pickering 5-8 plant-limiting HCLPF is 0.18g as per [B.24-85]. The DBE is 0.05g for the site [B.24-86]. This demonstrates that there is greater than 1.67 times margin between the RLE and the existing DBE. However, the margin between the new plant 10^{-4} occ/yr DBE and the Beyond	Safety Factor 1 (Plant Design)

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	Design Basis Earthquake referred to has not been confirmed. Hence, this is a PSR2 gap relating to Beyond Design Basis Earthquake qualification requirement margin.	
7.14 In-service testing, maintenance, repair, inspection and monitoring The clause details high level requirements for facilitation of the above to be considered and addressed in the plant design.	This is a new clause that was not in RD-337. Surveillance and repair of SSCs is addressed by the following OPG programs: • N-PROG-MA-0026, "Equipment Reliability" • N-PROG-MA-0017, "Component and Equipment Surveillance" • N-PROG-MA-0025, "Major Components" • N-PROG-MP-0008, "Integrated Aging Management" • N-PROG-MP-0014, "Reactor Safety Program" • N-STD-RA-0033, "Reliability Monitoring And Reporting Of Systems Important To Safety" In addition, the clause refers to the following codes that are included in the scope of the PSR2 code reviews per [B.24-9]: • REGDOC-2.6.3, "Aging Management" • CSA N287.7, "In-service Examination and Testing Requirements for Concrete Containment" • CSA N285.4, "Periodic Inspection of CANDU Nuclear Power Plant Components" • CSA N285.5, "Periodic Inspection of CANDU Nuclear Power Plant Components" • CSA N291, "Requirements for Safety-Related Structures for CANDU Nuclear Power" Therefore, at a high level Pickering has addressed the requirements of	**Compliant** Also addressed in other PSR2 code reviews.

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	this clause with having the capability to perform adequate surveillance and maintenance and is compliant for PSR2.	
7.15 Civil structure This clause is subdivided into three sub-sections: • Structure Design • Surveillance of Structures • Handling of large loads	Heading	n/a
7.15.1 Structural Design *The NPP design shall specify the required performance for the safety functions of the civil structures in operational states, DBAs and DECs.* *Civil structures important to safety shall be designed and located so as to minimize the probabilities and effects of internal hazards such as fire, explosion, smoke, flooding, missile generation, pipe whip, jet impact, or release of fluid due to pipe breaks.* *External hazards such as earthquakes, floods, high winds, tornadoes, tsunamis, and extreme meteorological conditions shall be considered in the design of civil structures.* *….* *The design should identify all DEC loads considered in the structure design and provide the assessment methodology and acceptance criteria.*	Clause 7.15.1 in RD-337 was previously generic to all safety-related structures and did not differentiate between containment and other structures. Pickering structural design has been assessed to meet and facilitate all DBA safety credits. The requirement relating to DECs is a new requirement and is applicable to all structures. Pickering structures were not specifically designed for some external DECs. However, assessments for all hazards have been completed. Internal and external hazard assessments have been done for Pickering as part of screening for the PSA per [B.24-72] and [B.24-73]. The screening assesses the impact of the hazards on structures. Those hazards that cannot be screened out based on low frequency and/or consequences are subjected to further assessment. All internal hazards have been explicitly analyzed or screened out. Only external hazards relating to high wind and seismic were subject of additional assessment in terms of structural capability. The Pickering units' nuclear safety success paths for high wind DECs have been addressed in the PSAs [B.24-87] and [B.24-88]. Although some structural vulnerabilities were identified, there were alternate	**Compliant**

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	success paths available or the overall risk from failures was acceptably low. Assessments for Pickering Units 1,4 and 5-8, have been addressed in the seismic PSAs [B.24-85] and [B.24-86]. These have demonstrated that the credited safety-related structures are sufficiently robust that they will support the required safety functions for DEC seismic events. Based on the above, it is concluded that the Pickering plant structural design is sufficiently robust to provide assurance that the required nuclear safety functions will be available for DEC conditions. Therefore, Pickering is compliant with this clause.	
Containment Structures *The design should specify the safety requirements for the containment building or system, including, for example, its structural strength, leak tightness, and resistance to steady-state and transient loads (such as those arising from pressure, temperature, radiation, and mechanical impact) that could be caused by postulated internal and external hazards…*	Safety requirements for the Pickering 1,4 and 5-8 Containment structures are addressed in the Operational Safety Requirements [B.24-89] and [B.24-90]. The clause also specifies requirements for the CSA N287 series of standards for concrete containment structures: • N287.1, General Requirements • N287.2, Material Requirements for Concrete Containment Structures • N287.3, Design Requirements • N287.4, Construction, Fabrication and Installation Requirements • N287.5, Examination and Testing Requirements • N287.6, Pre-operational Proof and Leakage Rate Testing Requirements The N287 reviews are being addressed in separate code reviews as part of PSR2 as defined in the PSR2 basis document [B.24-9].	Addressed in other code reviews. PSR2 CSA N287 Gap

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
Safety-related structures *The safety-related structures other than the containment should be designed and constructed in accordance with CSA N291, "Requirements for safety-related structures for CANDU nuclear power plants."*	The introduction of CSA N291 [B.24-91] [B.24-89] is a new requirement that was not previously included in RD-337. However, a separate PSR2 review is being performed for this code.	Addressed in other PSR2 code review. PSR2 CSA N291-15 Gap
7.15.2 Surveillance *The design shall enable implementation of periodic inspection programs for structures important to safety in order to verify that the as-constructed structures meet their functional and performance requirements.* *The design shall also facilitate in-service monitoring for degradations that may compromise the intended design function of the structures. In particular, the design shall permit monitoring of foundation settling.* *Pressure and leak testing shall be conducted on applicable structures to demonstrate that the respective design parameters comply with requirements.* *The design shall facilitate routine inspection of sea, lake, and river flood defences and demonstrate fitness for service.*	Clause 7.15.2 was a gap for the Darlington RD-337 [B.24-21] review relating to Periodic Inspection Programs. The periodic inspection requirements for containment are addressed under 7.15.1 above. The surveillance requirements in REGDOC-2.5.2 also apply to safety-related structures. Pickering has established inspection specifications for safety related structures [B.24-92]. Pickering has established a surveillance (Preventative Maintenance ID) for the periodic inspection and is in the process of implementing the Inspection and Test Plan. Any issues identified during the inspection will be addressed via the corrective action program, hence, Pickering is compliant with this requirement for PSR2.	**Compliant**
7.15.3 Lifting and Handling of Large Loads *The lifting and handling of large and heavy loads, particularly those containing radioactive material, shall be considered in the NPP design…* *The drop of large loads lifted and handled in areas where there are systems and components that are important to safety shall be taken into account in the design. The potential load due to the large load drop shall be taken into account in the analysis of DBAs.*	As part of the Hazard Screening reviews for Pickering [B.24-72] and [B.24-73], dropping of heavy loads during craning has been screened out based on low frequency of exposure. For Pickering, craning in the Reactor Building Boiler Rooms is not possible at power and it is a prerequisite that the reactor be shutdown and in a Guaranteed Shutdown State. Specific assessments have been performed for flasking over and around the Reactivity Mechanism Decks at Pickering and the risk of load drops and consequential damage has been evaluated and determined to be acceptable.	**Compliant**

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	In general, hoisting over safety-related equipment/systems (e.g., Class III power, Service Water piping) is evaluated in lift planning and is governed by N-STD-MA-0018 [B.24-93] "Hoisting And Rigging", which identifies the process and management controls for hoisting operations, and the inspection and maintenance of lifting devices and rigging equipment. Pickering is compliant for PSR2.	
7.16 Construction and Commissioning This clause identifies high level requirements relating to ensuring that the new plant design addresses constructability and facilitates design confirmation including functional and performance testing.	Pickering is a mature plant, however, all modifications must adhere to the Engineering Change Control (ECC) process [B.24-75]. The ECC process requires that Constructability, Operability, Maintainability and Safety (COMS) be addressed [B.24-94]. The Modification Process [B.24-95] identifies the method of testing the modification and specifications for the testing are prepared in accordance with [B.24-96]. Pickering is compliant with this requirement.	**Compliant**
7.17 Aging and wear *The design shall take due account of the effects of aging and wear on SSCs. For SSCs important to safety, this shall include: …*	A reference to RD-334 "Aging Management" has been introduced and is a new requirement. However, it has already been superseded by REGDOC-2.6.3. An incremental review of REGDOC-2.6.3 has been performed as part of PSR2 and is documented in [B.24-68]. Two gaps have been identified against Safety Factor 4. This is a PSR2 gap.	Addressed in other PSR2 Safety Factor and code review. PSR2 REGDOC-2.6.3 Gap
7.18 Control of Foreign Material *The design provides for exclusion and removal of all foreign material and corrosion products that may have an impact on safety.*	This clause specifically relates to foreign material resulting from process system operation as opposed to that generated during maintenance activities. Systems (e.g., Heat Transport Pressure and Inventory Control, Moderator, Liquid Zone Control, Fuel Handling) and that are exposed to radiation levels where foreign	**Compliant**

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	material exposure to radiation could result in activation products are designed with concentrators (strainers, filters, ion exchange) to remove foreign material. This is performed for radiological safety and maintainability reasons. Pickering is compliant with this requirement.	
7.19 Transport and packaging of fuel and radioactive waste The clause identifies the high level requirements that handling of new and used fuel must be addressed in the design.	The handling of new and used fuel is addressed at a high level in the Pickering Safety Report Part 2, Section 10 of [B.24-54] and [B.24-55]. Additionally, radioactive waste management is addressed in Section 13 of [B.24-54] and [B.24-55]. Additional details can be found in the applicable system Design Manuals and operating procedures. Pickering is compliant with this requirement.	**Compliant**
7.20 Escape routes and means of communication *The design shall provide a sufficient number of safe escape routes that will be available in operational states, DBAs and DECs, including seismic events. These routes shall be identified with clear and durable signage, emergency lighting, ventilation and other building services essential to their safe use.*	Fire protection, communication and emergency lighting are addressed the Pickering Safety Report Part 2, Section 11.5 of [B.24-54] and [B.24-55]. Additionally, code reviews are being performed for 2010 versions of the "National Building Code of Canada" (NBCC) and "National Fire Code of Canada" (NFCC), as specified in [B.24-9]. These have specific requirements relating to emergency egress. There is also a requirement that egress from containment be available regardless of containment pressure. This is addressed in Containment Airlock designs as detailed in Section 3.2.3 of [B.24-54] for Pickering 1, 4 and Section 3.2.4 of [B.24-55] Pickering 5-8. Pickering has clearly delineated seismic pathways and areas for safe operator access, occupancy and escape from threatened areas as documented in [B.24-97] and [B.24-98]. Pickering is compliant with this requirement.	**Compliant** Also addressed in other PSR2 Safety Factor and code reviews.

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
7.21 Human factors *The design shall include a human factors engineering program plan. Relevant and proven systematic analysis techniques shall be used to address human factors issues within the design process….*	This clause was a gap for RD-337 [B.24-21] for Human Factors and has been addressed in Darlington ISR Issue D260 in Section B.24.2.1 above. This clause has been revised from the previous clause in RD-337 to include significantly more background and guidance. Pickering 5-8 and more so, Pickering 1,4 design predates the formalized standards for application of human factors engineering (HFE) to nuclear power. Rather, the Pickering plant designs were based on the 'best practice' of the day and reflected operating experience from earlier nuclear plants including the Nuclear Power Demonstration plant, Douglas Point, and in the case of Pickering 5-8, Bruce A and Pickering A. Furthermore, OPG (formally Ontario Hydro) had extensive experience with control center and plant design based on experience from both fossil fueled and hydro power plants. Since the original plant designs, significant operating experience has been acquired and improvements incorporated relating to integration of human factors into the existing plant. Such areas include; improved annunciation prioritization, and display systems; nuisance alarm reduction; improved procedures including annunciation response manuals, etc. Training and use of the full scope simulators allows operators to simulate and practice procedures and response to normal evolutions and upset plant response. Procedure validation, pre-job briefings, table tops, field walkthroughs, and procedure adherence, facilitate safe and effective human interface with the plant. As demonstrated in the review of Human Factors as part of the PSR2 code reviews and the Plant Design Safety Factor, Pickering for many	**<u>PSR2 REGDOC-2.5.2 Gap #8</u>** (Human Factors in Design) Safety Factor 1 (Plant Design)

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	years has had a fully compliant human factors program applicable to plant modifications. Although the original plant design predates the more structured application of HFE to the design, many of the important elements of HFE have been retroactively integrated into plant operations. However, the absence of systematic application of HFE principles to the original plant design is a PSR2 REGDOC-2.5.2 Gap #8 (Human Factors in Design).	
7.22 Robustness against malevolent acts	Not in the PSR2 scope.	n/a
7.23 Safeguards	Not in the PSR2 scope.	n/a
7.24 Decommissioning *Future plant decommissioning and dismantling activities shall be taken into account, such that:* *…*	Decommissioning is not within the scope of PSR2.	n/a
8. System-Specific Requirements	Heading	n/a
8.1 Reactor core This clause deals with a broad range of reactor core related issues, including: • Mechanical/structural design • Aging • Reactor physics (e.g., criticality, power density, reactivity, stability) • Core management In addition, there are two subsections: 8.1.1 Fuel design 8.1.2 Control system *Reactor core parameters and their limits shall be specified. The design shall consider all foreseeable reactor core configurations for normal operation.* *The reactor core, including the fuel elements, reactivity control mechanisms, reflectors, fuel channel and structural parts, shall be designed so that the reactor can be shutdown, cooled and held subcritical with an adequate margin in operational states, DBAs and DECs. …*	The high level reactor core design is described in Part 2 of the Safety Report Section 4 of [B.24-54] and [B.24-55]. Structural design codes for the reactor core are addressed in PSR2 under the CSA N285 series of code reviews per [B.24-9]. Aging is addressed in [B.24-68] as part of PSR2. The original reactor core physics design is addressed in [B.24-99] and [B.24-100], for Pickering 1,4 and Pickering 5-8 respectively. Fuel Design Manuals for both Pickering are included under the 37000 USI. The Operational Safety Requirements for Fuel and Reactor Physics [B.24-101] and [B.24-102] address the safety analysis assumptions and credits relating to the core design. Stability and reactivity management were addressed in the PSR2 CSA N290.4 [B.24-79] code review. There was one Gap identified	**Compliant** Also, addressed in other PSR2 Safety Factor and code reviews.

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
The design limits for power densities (and thus for peaking factors) during normal operation should be such that acceptable fuel design limits are not exceeded during AOOs and that other limits are not exceeded during DBAs and DECs…	relating to Reactor Regulating System credits for AOOs. This does not represent a gap against this clause. The DEC requirement relating to sub-criticality is new and did not appear in RD-337. However, maintaining sub-criticality is addressed in BDBA and SAMG, and hence this is not a gap (See clause 7.3 above). Also, the DEC fuel design requirements are new. The reference DEC case for Emergency Mitigating Equipment [B.24-103] credits the boilers as the long term heat sink. This does not result in conditions any more severe than a Seismic Event, which is already addressed in DBA analysis. Sensitivity DEC cases with HTS leakage, or where the HTS void becomes sufficiently large that the boilers cannot be maintained as a heatsink, can result in elevated fuel temperatures until HTS make-up can be established. DEC with moderator as the ultimate Heat Sink can result in a significant fission product release to the HTS and Containment, even though fuel channel integrity and coolable fuel geometry is maintained. Hence, although no explicit design limits for fuel have been established for DECs, there are qualitative objectives for CDFs and BDBA response that address this issue. Therefore, Pickering is compliant with this clause.	
8.1.1 Fuel elements, assemblies and design *Fuel assembly design shall include all components in the assembly, such as the fuel matrix, cladding, spacers, support plates, movable rods inside the assembly etc. The fuel assembly design shall also identify all interfacing systems…*	The design basis relating to fuel design is provided in the clause immediately above. In addition, performance of fuel for DBAs is evaluated extensively in the Safety Report Part 3 – Accident Analysis [B.24-56] and [B.24-57], for	**Compliant** Also, addressed in other PSR2 code reviews.

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	Pickering 1,4 and Pickering 5-8 respectively. As part of PSR2 a review of CNSC REGDOC-2.4.1 [B.24-14] is being performed for Deterministic Safety Analysis. No gaps have been identified relating to fuel design or performance. Pickering is compliant with this clause.	
8.1.2 Control systems *The design shall provide the means for detecting levels and distributions of neutron flux. This shall apply to neutron flux in all regions of the core during normal operation (including after shutdown and during and after refuelling states), and during AOOs.* *The reactor core control system shall detect and intercept deviations from normal operation with the goal of preventing AOOs from escalating to accident conditions.*	The details in this clause are addressed in the PSR2 CSA N290.4 [B.24-79] code review. There was one Gap identified relating to Reactor Regulating System credits for AOOs. This has been identified as a PSR2 gap relating to CSA N290.4.	Addressed in other PSR2 code review PSR2 CSA N290.4-11 Gap
8.2 Reactor coolant system *The design shall provide the reactor coolant system (RCS) and its associated components and auxiliary systems with sufficient margin to ensure that the appropriate design limits of the reactor coolant pressure boundary are not exceeded in operational states or DBAs.* *The design shall ensure that the operation of pressure relief devices will not lead to significant radioactive releases from the plant, even in DBAs. The RCS shall be fitted with isolation devices to limit any loss of radioactive coolant outside containment.* *The material used in the fabrication of the component parts shall be selected so as to minimize corrosion and activation of the material.* *Operating conditions in which components of the pressure boundary could exhibit brittle behaviour shall be avoided.* *The design shall take into account all conditions of the boundary material in normal operation (including maintenance and testing), AOOs, DBAs and DECs, as well as expected end-of-life properties affected by aging mechanisms, the rate of*	The high level description of the Heat Transport System (HTS) design is provide in Part 2 of the Safety Report Sections 4 and 5 [B.24-54], [B.24-55], for Pickering 1,4 and Pickering 5-8 respectively. Additional detail can be found in the HTS Design Manuals under USI 33100. The requirement for aging combined with DEC conditions is a new requirement. No explicit treatment of DECs has been included in HTS aging. Although a gap has been identified against the PSR2 Aging Safety Factor review relating to operation beyond 2020, this does not specifically deal with DEC requirements. Assessments of DECs have not identified any vulnerabilities with respect to safely shutting down the reactor(s). This is because SDS trips are assumed to occur due to loss of AC power (e.g., loss of Class IV/III), and resultant HTS, Feedwater or manual trips. Also, the Shutdown	**Compliant**

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
deterioration, and the initial state of the components.	and Regulating systems are designed to fail safe on loss of control power to logic and reactivity mechanisms (Shutoff Rods, Liquid Injection Shutdown System valves, Control Absorbers and Dump Valves). The DEC assessment objective is to minimize the risk of fission product release and to maintain HTS integrity, by maintaining the containment envelope and establishing a long term heat sink, and, hence is achieved. The reference cases for DECs at Pickering 5-8 have the boilers maintained as the long-term heat sink. The limiting case DEC for HTS integrity is a seismic event rather than high wind (Tornado), flooding or fire. All events are assumed to result in a loss of AC power. Per the Seismic PSA [B.24-85], the HTS has been shown to have large margins for DECs. HTS over pressure protection was addressed as part of the Fukushima FAI-1.1.1 [B.24-53]. If the long term boiler heat sink fails or is unavailable for a DEC, the HTS pressure boundary is assumed to eventually fail due to a loss of inventory. Once HTS failure occurs either a HTS make-up heat sink or moderator heatsink is credited. Hence, maintaining HTS integrity is not a requirement for these conditions. For Pickering 1,4, the Shutdown Cooling System is used as the HTS heat sink for the seismic DECs. The Seismic Margin Assessment (SMA) [B.24-84] has shown that HTS and support systems are suitably qualified for the seismic RLC. Similar to Pickering 5-8, if the SDC or Boiler Heat sink fail, either a HTS or moderator make-up heat sink is credited. Hence, maintaining HTS integrity is not a requirement for these conditions. Given that a DEC assessment should be based on 'best estimate' and	

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	'reasonable confidence', whereas HTS fitness for service and stress limits are based on bounding deterministic assumptions, HTS pressure boundary integrity in order to support a long-term heat sink would not be challenged by aging. Rather, requirements for DBA mitigation are more limiting than those for DECs. Sensitivity cases for DECs are evaluated with consequential HTS leakage. For DECs where the HTS is open prior (e.g., outage) or where a random DEC LOCA occurs, the HTS pressure boundary is already failed, hence, aging is not an issue. Therefore, although Pickering does not have any explicit assessments of DEC conditions with an aged HTS, based on analysis and assessments completed, this is not a safety issue. Therefore, Pickering is compliant with this clause.	
8.2.1 In-Service pressure boundary inspections *The components of the reactor coolant pressure boundary shall be designed, manufactured, and arranged in a manner that permits adequate inspections and tests of the boundary, support structures and components throughout the lifetime of the plant.* *The design shall also facilitate surveillance in order to determine the metallurgical conditions of materials for which metallurgical changes are anticipated.*	Surveillance of the HTS is addressed by the following OPG programs: • N-PROG-MA-0025, "Major Components" • N-PROG-MP-0008, "Integrated Aging Management" In addition, the clause refers to the following codes that are included in the scope of the PSR2 code reviews: • REGDOC-2.6.3, "Aging Management" • CSA N285.4, "Periodic Inspection of CANDU Nuclear Power Plant Components" Pickering is compliant with this clause.	**Compliant**

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
8.2.2 Reactor coolant system inventory *Taking volumetric changes and leakage into account, the design shall provide control of coolant inventory and pressure so as to ensure that specified design limits are not exceeded in operational states. This requirement shall extend to the provision of adequate capacity (flow rate and storage volumes) in the systems performing this function.* *The inventory in the RCS and its associated systems shall be sufficient to support cool down from hot operating conditions to zero-power cold conditions without the need for transfer from any other systems.*	There was a gap for Darlington for this clause 8.2.2 [B.24-21] and Issue D227 [B.24-35], relating to the amount of D_2O inventory in a unit. This is not a PSR2 gap as there is sufficient inventory available in each Pickering unit to accommodate HTS cooldown of all units (see assessment in Section B.24.2.1, above).	**Compliant**
8.2.3 Reactor coolant system cleanup *The design shall provide for adequate monitoring and removal of impurities and radioactive substances from the reactor coolant, including activated corrosion products and fission products leaking from the fuel. The safety limit for activity in the reactor coolant shall be defined.*	The Pickering HTS systems have connected purification circuits as detailed in Part 2 of the Safety Report Section 5 [B.24-54], [B.24-55] for Pickering 1,4 and 5-8 respectively. Limits for radioactive content of the HTS are provided in the HTS Operational Safety Requirements [B.24-36] and [B.24-37]. Therefore, Pickering is compliant with this clause.	**Compliant**
8.2.4 Removal of residual heat from reactor core *The design shall provide a means (i.e., backup) of removing residual heat from the reactor for all conditions of the RCS. The backup shall be independent of the configuration in use.*	Pickering units have several residual heat removal mechanisms as detailed in the Safety Reports–Part 2 [B.24-54], [B.24-55]. These are: • SRVs with Boilers supplied by inventory from normal or auxiliary feed water or Pickering 1,4 EBWS or Pickering 5-8 EWS. • Shutdown Cooling Heat Exchangers supplied by normal or emergency high pressure service water. • Emergency heat removal with High Pressure Emergency Coolant Injection (HPECI) and ECI recovery, with Reactor Building Air Coolers. • Additionally, Pickering 5-8 has emergency heat removal with EWS to the HTS. Pickering 1,4	**Compliant**

REDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	has a Firewater supply to either the HTS or Moderator. Therefore, Pickering is compliant with this clause.	
8.3.1 Steam lines *The steam piping up to and including the turbine generator governor valves and, where applicable, the steam generators shall allow sufficient margin to ensure that the appropriate design limits of the pressure boundary are not exceeded in operational states and DBAs. This provision shall take into account the operation of control and safety systems.* *The main steam isolation valves (MSIVs) shall be installed in each of the steam lines leading to the turbine, and located as close as practicable to the containment structure.*	Pickering satisfies all requirements in this clause except that the units do not have Main Steam Isolation Valves. For both Pickering 1,4 and Pickering 5-8, Safety Analysis for Main Steam Line Breaks has been performed with the assumption that the break is not isolated, Appendix 7 of [B.24-56] and [B.24-57] for Pickering 1,4 and Pickering 5-8 respectively. This analysis assumption maximizes the harsh environment (temperature, pressure and humidity) conditions in the Powerhouse [B.24-104] and [B.24-105]. The environmental qualification and qualified success path is established based on these bounding conditions. The reactor safety consequences have been demonstrated to be acceptable in the absence of break isolation. Therefore, this issue is not considered to be safety significant. Additionally, Pickering has performed Containment analysis with steam line breaks inside containment without credit for isolation and demonstrated acceptable consequences. While MSIVs could also be used to establish a secondary containment if the primary boundary fails (e.g., boiler tube(s), steam line), boiler tube failures can be isolated by existing boiler isolating valves while the closed main steam supply loop remains intact as a boundary for pipe breaks inside containment. Finally, as noted in REGDOC-2.5.2, remote manual action cannot be credited before 30 minutes, therefore manual closure of MSIVs would have minimal benefit in terms of reducing consequences. Automatic closure of MSIVs would need to have sufficient reliability both for closure and avoidance of spurious closure.	**Compliant**

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	Based on the above, the provision of MSIVs is not significantly beneficial from a reactor safety perspective and the absence of MSIVs has acceptable safety consequences. Therefore, Pickering is compliant with this clause.	
8.3.2 Steam and feedwater system piping and vessels *All piping and vessels shall be typically separated from electrical and control systems, to the extent practicable…*	Pickering 5-8 credits the Group 2 systems for Steam and Feedline failures. Pickering 1,4 has hardened and/or protected systems credited for Steam and Feedline failures. Critical control (including personnel) and electrical equipment for the main control rooms has been protected by providing a steam protection barrier between the Reactor Auxiliary Bay and the Turbine Auxiliary Bay. Therefore, Pickering is compliant with this clause.	**Compliant**
8.3.3 Turbine generators *The design shall provide over-speed protection systems for the turbine generators to minimize the probability of turbine disk failure leading to generation of missiles.* *The design shall be such as to minimize the potential for any missiles from a turbine break-up striking the containment, or striking other SSCs important to safety.*	This clause 8.3.3 was a gap for Darlington [B.24-21] (Issue D278) [B.24-38]. This issue was closed because failure resulting in missiles was explicitly analyzed and demonstrated acceptable. This was previously assessed in C-6 R1 reviews for Pickering Units 1,4 and Units 5-8 and is addressed in the PSR2 Hazard Analysis Safety Factor report and the Hazard Analysis screening [B.24-72], [B.24-73] for Pickering 1,4 and Pickering 5-8 respectively. These assessments are consistent with the 'minimize probability' requirement, hence, this is not a PSR2 gap.	**Compliant**
8.4 Means of shutdown *The design shall provide means of reactor shutdown capable of reducing reactor power to a low value, and maintaining that power for the required duration,…* *The design shall include two separate, independent, and diverse means of shutting down the reactor.*	Pickering 5-8 has two fully independent and diverse shutdown systems and is compliant with this requirement. Pickering 1,4 has two means of reactor shut down with independent parameters and logic using SDSA and SDSE. The shutoff rods and	**Compliant** Addressed in other PSR2 code review.

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
At least one means of shutdown shall be independently capable of quickly rendering the nuclear reactor subcritical from normal operation in AOOs and DBAs, by an adequate margin, on the assumption of a single failure. For this means of shutdown, a transient recriticality may be permitted in exceptional circumstances if the specified fuel and component limits are not exceeded.	dump valves are initiated from either of the two logic trains. This configuration was an acceptable deviation for PSR1 and was assessed for PSR2 as part of the CSA 290.1 [B.24-78] standard review. Pickering is compliant with this clause for PSR2.	
8.4 Means of shutdown (Con't) *…* *Means shall be provided to ensure that there is a capability to shut down the reactor in DECs, and to maintain the reactor subcritical even for the most limiting conditions of the reactor core, including severe degradation of the reactor core….*	Light water addition is available for HTS or Moderator addition at both Pickering 1,4 and Pickering 5-8 from installed systems or EME water. This was addressed in SAMG via the SAG-2 guideline, hence, this is not a PSR2 gap.	**Compliant**
8.4.1 Reactor trip parameters *The design authority shall specify derived acceptance criteria for reactor trip parameter effectiveness for all AOOs and DBAs, and shall perform a safety analysis to demonstrate the effectiveness of the means of shutdown.* *For each credited means of shutdown, the design shall specify a direct trip parameter to initiate reactor shutdown for all AOOs and DBAs in time to meet the respective derived acceptance criteria. Where a direct trip parameter does not exist for a given credited means, there shall be two diverse trip parameters specified for that means.* *For all AOOs and DBAs, there shall be at least two diverse trip parameters unless it can be shown that failure to trip will not lead to unacceptable consequences.*	AOO Safety Analysis has not been completed for Pickering and this has been identified as a PSR2 gap. However, the issue of AOO analysis is identified under the Deterministic Safety Analysis Safety Factor review and the code review for CNSC REGDOC-2.4.1. Therefore, this is not repeated as a PSR2 gap against REGDOC-2.5.2.	Addressed in other PSR2 code reviews. PSR2 REGDOC-2.4.1 Gap
8.4.2 Reliability *The design shall permit ongoing demonstration that each means of shutdown is being operated and maintained in a manner that ensures continued adherence to reliability and effectiveness requirements…*	Compliance with this requirement is evidenced by the shutdown system reliability target, actual past unavailability and predicted future unavailability as documented in the Annual Reliability report [B.24-76] relating to shutdown systems. Therefore, Pickering is compliant with this clause.	**Compliant**
8.4.3 Monitoring and operator action *Once automatic shutdown is initiated, it shall be impossible for an operator to prevent its actuation.*	This is the same requirement that is in Clause 4.3.5.4 of CSA N290.1, "Requirements for the Shutdown	**Compliant**

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	Systems" [B.24-78], which was reviewed as part of PSR2 and was compliant. Once a 2 of 3 channel trip seals-in, a trip cannot be reset. The trip seal-in timer is provided to avoid spurious trips, however, its seal-in time is so short (<350 msec) [B.24-106], [B.24-107], that it is essentially impossible for an operator to intervene. Additionally, operator training and expectations dictate that they never interfere with automatic shutdown system action. Pickering is compliant with this clause.	
8.5 Emergency core cooling system (ECCS) *All ECCS components that may contain radioactive material shall be located inside containment or in an extension of containment. ECCS piping in an extension of containment that may contain radioactivity from the reactor core shall be subject to the following requirements:* *1. As a piping extension to containment, it meets the requirements for metal penetrations of containment.* *2. All piping and components of the ECCS recovery flow path piping that are open to the containment atmosphere are designed for a pressure greater than the containment design pressure.* *3. All ECCS recovery flow paths are housed in a confinement structure which prevents leakage of radioactivity to the environment and to adjacent structures.* *4. This housing includes detection capability for leakage of radioactivity, and the capability to either return the radioactivity to the flow path, or to collect the radioactivity and store (or process it) in a system designed for this purpose.* *Intermediate or secondary cooling piping loops shall have leak detection, whether the ECCS recovery system is inside or outside of containment, with the leak detection being such that upon detection of radioactivity from the ECCS recovery flow, the loops can be isolated as per the requirements for containment isolation.*	The ECI systems have been assessed as part of PSR2 in a review of CSA N290.2, "Requirements for Emergency Core Cooling Systems of Nuclear Power Plants" [B.24-110], and a gap was identified relating to recovery strainer instrumentation. All of ECI in Pickering 1,4 is inside containment including the Heat Exchangers (HXs). Because the HXs are common to the Moderator system, leak detection is available. Therefore, Pickering 1,4 is compliant. Pickering 5-8 has the ECI recovery piping, pumps and HXs outside of Containment. Components penetrating and outside containment are all DBE qualified and nuclear Class 2 [B.24-108], in accordance with the Design Guide [B.24-109]. The system has leakage collection, recovery and radiation monitoring in the vicinity. However, there is no direct leak detection for an ECI recovery HX tube leak. This clause is therefore a PSR2 Gap.	**PSR2 REGDOC-2.5.2 Gap #9** (Detection/Isolation of ECI HX Tube Leak) Safety Factor 1 (Plant Design)

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
8.6 Containment There are twelve sub-clauses relating to Containment. These are: 8.6.1 General 8.6.2 Strengthen (sic) of the containment structure 8.6.3 Capability for pressure test 8.6.4 Leakage 8.6.5 Penetrations 8.6.6 Isolations 8.6.7 Airlocks 8.6.8 Internal Structures 8.6.9 Containment Pressure and Energy Management 8.6.10 Control and cleanup of containment atmosphere 8.6.11 Coverings, coatings and materials 8.6.12 Design extension conditions	A review of CSA N290.3, "Requirements for the Containment System" [B.24-111], has been performed as part of PSR2. This review also includes assessing the requirements that were only applicable to a new plant. Only one gap was identified relating to the Energy Management System (EMS) and Phase 2 EME not being fully implemented. The approach to the assessment of the sub-section requirements is to only evaluate incremental requirements that were not assessed in the CSA 290.3 review. These are addressed in the subsections below.	**Compliant**
8.6.1 General *Leakage rate limits* …. **Guidance** *A modern containment should be able to achieve a leakage rate less than 0.5% containment air mass per day at the maximum containment pressure from any DBA. For example, modern designs achieve a maximum leakage rate of 0.1% to 0.5% containment air mass per day at design pressure.*	Pickering demonstrates compliance with the licence and safety leakage limits in the Operating Policies & Principles (OP&Ps) and the Containment Operational Safety Requirements [B.24-89], [B.24-90]. These are 2% Vol/hr for Pickering 5-8 and 2.7% Vol/hr for Pickering 1,4 at design pressure of 41.4 kPa(g). All units use an operational leakage target of <1% Vol/hr. However, Pickering has a Negative Pressure Containment System (NPCS). Following a DBA which requires the NPCS to activate, pressure in the accident Reactor Building is quickly reduced and controlled at a pressure dictated by the Instrumented Pressure Relief Valves (e.g., at a Reactor Building pressure <~4.5 kPa(g)) [B.24-89], [B.24-90]. The guidance provided in this clause is applicable to a new single unit plant with a lined (typically steel lined) containment. Such a unit may be predicted to have significant prolonged high pressure in containment for DBAs. Hence, the leakage rates referred to are not	**Compliant**

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	applicable to a multi-unit design with NPCS. Therefore, this issue is not a PSR2 gap.	
8.6.5 Containment penetrations *The number of penetrations through the containment shall be kept to a minimum.* *All containment penetrations shall be subject to the same design requirements as the containment structure itself, and shall be protected from reaction forces stemming from pipe movement or accidental loads, such as those due to missiles generated by external or internal events, jet impact, and pipe whip.* *All penetrations shall be designed to allow for periodic inspection and testing.* *If resilient seals such as elastomeric seals, electrical cable penetrations, or expansion bellows are used with penetrations, they shall have the capacity for leak testing at the containment design pressure. To demonstrate continued integrity over the lifetime of the plant, this capacity shall support testing that is independent of determining the leak rate of the containment as a whole.*	Darlington was compliant for Clause 8.6.5 of RD-337 [B.24-21]. Darlington was designed and built with testable penetrations but it does not rely on them for in service leak detection. Per the RD-337 Compliance Discussion for Clause 8.6.4 [B.24-21], Darlington relies on the operational leak rate testing to confirm containment is sufficiently leak tight. With very few exceptions, Pickering does not have testable penetrations. Similar to Darlington, Pickering relies on operational leak rate testing and PIP testing to confirm the leak tightness of containment. Operational pressure testing of the containment envelope is conducted via several, sometimes overlapping, tests identified in the Appendices of [B.24-76]. As part of CSA N287.7 compliance, full Reactor Building Pressure tests are required every 6 years and a Negative Pressure Containment pressure test is required every 10 years [B.24-2]. A review of Pickering 5-8 against CSA N285.3-88 is included in Reference [B.24-10]. For CSA N285.3 Clause 7.8.4 relating to penetration testing, Pickering 5-8 was compliant. Given the above, although Pickering does not have individually testable electrical penetrations, this is considered to be acceptable based on the suitable alternate surveillance/testing being performed to assure the safety function is maintained. Therefore, this issue is not a PSR2 gap.	**Compliant**

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
8.6.8 Internal structures of the containment *The design shall provide for ample flow routes between separate compartments inside the containment. The openings between compartments shall be large enough to prevent significant pressure differentials which may cause damage to load-bearing and safety systems during AOOs, DBAs and DECs.* *The design of internal structures shall consider the hydrogen control strategy, and assist in the effectiveness of that strategy.…*	Clause 8.6.8 was a gap for RD-337 for Darlington [B.24-21], relating to treatment of hydrogen. Treatment of hydrogen in containment has been addressed for Pickering per the FAI [B.24-12] closure which included the installation of Passive Autocatalytic Recombiners and improvements to SAMG hydrogen determination. Hydrogen produced for DBA is addressed by hydrogen igniters, PARs and by assessment of standing flame consequences. Relief paths between compartments inside the Pickering Reactor Buildings, the Pressure Relief Duct and Vacuum Building were addressed in the design for DBAs and limit the pressure differentials across credited structures and equipment. The credited relief and pressure equalization features are referenced in the Containment OSRs (References [B.24-89] and [B.24-90]) and in the 21000 USI series of Design Manuals. DECs do not introduce incremental requirements relating to flowpaths and pressure equalization. Limiting static differential pressure due to water level is addressed in BDBA and SAM guidelines. Therefore, this is not a PSR2 gap.	**Compliant**
8.6.9 Containment pressure and energy management *The design shall enable heat removal and pressure reduction in the reactor containment in operational states, DBAs and DECs. Systems designed for this purpose shall be treated as part of the containment system, and are capable of:* *1. minimizing the pressure-assisted release of fission products to the environment* *2. preserving containment integrity* *3. preserving required leak tightness*	The introduction of DEC is a new requirement and the energy management system (EMS) has been addressed in other PSR2 code reviews. There was a gap in the CSA N290.3 "Requirements for the Containment System" [B.24-111] and the REGDOC-2.3.2 "Accident Management" [B.24-44], because Phase 2 EME has not yet been fully implemented to support the EMS. This is a PSR2 gap.	Addressed in other PSR2 code reviews. PSR2 CSA N290.3-11 Gap PSR2 REGDOC-2.3.2 Gap

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
8.6.10 Control and cleanup of the containment atmosphere *The design shall provide systems to control the release of fission products, hydrogen, oxygen, and* *other substances into the reactor containment, as necessary, to:* *1. reduce the amount of fission products that might be released to the environment during an accident* *2. prevent deflagration or detonation that could jeopardize the integrity or leak tightness of the containment …*	Clause 8.6.10 was a gap for RD-337 for Darlington [B.24-21] relating to there not being hydrogen mitigation for DECs. PARs have been installed at Pickering, hence this is not a PSR2 gap.	**Compliant**
8.6.11 Coverings, coatings and materials *The coverings and coatings for components and structures within the containment shall be carefully selected, and their methods of application shall be specified to ensure fulfillment of their safety functions. …*	This issue was assessed for Pickering B ISR and classified as an AD. The conclusions are applicable to Pickering Units 1,4 (See discussion in Section B.24.2.1). This is not a PSR2 gap.	**Compliant**
8.6.12 Design extension conditions *Following onset of core damage, the containment boundary shall be capable of contributing to the reduction of radioactivity releases to allow sufficient time for the implementation of offsite emergency procedures. …* *The ability of the containment system to withstand loads associated with design extension conditions (DECs) shall be demonstrated in design documentation, and shall include the following considerations:* *1. various heat sources, including residual heat, metal-water reactions, combustion of gases, and standing flames* *2. pressure control* *3. control of combustible gases* *4. sources of non-condensable gases* *5. control of radioactive material leakage* *6. effectiveness of isolation devices* *7. functionality and leak tightness of airlocks and containment penetrations* *8. effects of the accident on the integrity and functionality of internal structures* *The design authority shall demonstrate that complementary design features have been incorporated that will:* *1. prevent a containment melt-through or failure due to the thermal impact of the core debris* *2. facilitate cooling of the core debris*	The SAMG related requirements have been closed for Pickering per Section B.24.2.1, above. The requirement that containment should not exceed the design leakage for DECs for a period (at least 24 hours per Guidance) is a new requirement. This imposes a requirement that containment venting should not be required for 24 hours. While this requirement can likely be achieved for DECs, where the Boilers remain an effective heatsink, it is likely unachievable if there is core damage with limited Containment energy management capability as identified in Clause 8.6.9 above. The Level 2 PSA addresses this issue from a risk perspective, however, it may not address the deterministic design requirement. Therefore, this Clause is a PSR2 gap relating to DEC containment leakage limits to support implementation of offsite emergency measures.	**PSR2 REGDOC-2.5.2 Gap #3** (Containment Leak Tightness for DECs) Safety Factor 1 (Plant Design)

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
3. minimize generation of non-condensable gases and radioactive products *4. preclude unfiltered and uncontrolled release from containment* ***Guidance*** *The containment leakage rate in DECs with core damage should not exceed the design leakage rate for a sufficient period to allow for the implementation of offsite emergency measures. This period should be demonstrated, with reasonable confidence, to be at least 24 hours…*		
8.8 Emergency heat removal system *The design shall include an emergency heat removal system (EHRS) which provides for removal of residual heat in order to meet fuel design limits and reactor coolant boundary condition limits…. If the design of the plant is such that the EHRS is required to mitigate the consequences of a DBA, then the EHRS shall be designed as a safety system. There shall be reasonable confidence that the EHRS will function during DECs, if required…*	Clause 8.8 was a gap for RD-337 for Darlington [B.24-21]. The Darlington gap related to a fire coincident with LOCA relying on the common Emergency Service Water System. This gap is not an issue for Pickering where fire water is supplied by diesel pumps (Pickering Units 1,4) [B.24-54] or High Pressure Service Water (Pickering Units 5-8) [B.24-55]. For Pickering 5-8, there is reasonable confidence that Emergency Power Supply (EPS) and EWS will be available as an EHRS for DECs. For Pickering 1,4, the EHRS relies on firewater or EME water supply to maintain fuel cooling for DECs. Therefore, Pickering is compliant with this clause.	**Compliant**
8.9 Electrical power systems *The design shall specify the required functions and performance characteristics of each electrical power system that provides normal, standby, emergency and alternate power supplies to ensure: …* Guidance… *The normal AC electrical power systems should have the capacity and capability to supply all plant electrical loads during operational states, DBAs and DECs.* *Normal AC power supplies should be designed to:* • *prevent deviations from normal operation*	A PSR2 code review has been performed for CSA N290.5 "Requirements for Electrical Power…" [B.24-112]. The only gap identified in the review related to treatment of AOOs, hence, this gap is not repeated in this review. DEC assessments have been performed for some EME power (i.e., EME generator connection and corresponding distribution). Provision has been established using existing distribution systems. The requirement for the 'normal AC electrical power' to have capability	Addressed in another PSR2 code review. PSR2 CSA N290.5-06 Gap

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
• *prevent single failures from impacting more than one redundant division of electrical power supply* *avoid preventable challenges to standby and emergency systems as a result of an electrical system disturbance, transient, or upset condition (e.g., turbine-generator trip)…*	for DBAs and DECs is new and seems to impose qualification for DEC conditions. (Note, the term 'normal' appears to be used to distinguish the existing plant systems from the 'Alternate AC power supply' in clause 8.9.3). The extent of qualification for the 'Normal AC power' is addressed in the clause below.	
8.9.1 Standby and emergency power systems *The standby and emergency power systems shall have sufficient capacity and reliability, for a specified mission time, and in the presence of a single failure to provide the necessary power to:* *1. maintain the plant in a safe shutdown state and ensure nuclear safety in DBAs and DECs* *2. support severe accident management actions* *Dedicated onsite fuel storage facilities shall have a sufficient quantity of fuel to operate standby and emergency power sources while supplying connected loads…*	The clause imposes DEC qualification on EPS (Pickering 5-8) and Class III (Pickering 1,4). Pickering 5-8 EPS and Emergency Power Generators (EPGs) have been assessed to have external DEC capability [B.24-113]. Pickering 1,4 Class III distribution and Standby Generators have been assessed for external DECs for a seismic event [B.24-84] and high wind [B.24-87]. However, vulnerabilities exist for high wind at DECs. Therefore, a probabilistic assessment has been performed to demonstrate acceptable consequences [B.24-87] . This approach acceptably addresses the DEC qualification for Pickering 1,4 power, and hence, this is not a PSR2 gap. Pickering is compliant with this clause.	**Compliant**
8.9.2 DC and uninterruptible power systems *The design of the direct current (DC) power systems and uninterruptible AC power systems (if applicable) shall specify operating mission times when performing the intended safety functions of the connected loads and meet the capacity requirements of section 7.10.…*	This is a new clause. Pickering is compliant and a PSR2 review for CSA N290.5 [B.24-112] has not identified any gaps relating to the Class I and II (AC and DC) power systems. Pickering is compliant with this clause.	**Compliant** Addressed in other PSR2 code review.
8.9.3 Alternate AC power supply *The electrical power system design shall include provisions for mitigating the complete loss of onsite and offsite AC power. This is accomplished by the use of onsite portable, transportable or fixed power sources or offsite portable or transportable power sources, or a combination of these…*	This clause imposes requirements on the 'Alternate' as opposed to 'Normal' power supply. 'Alternate' power is not addressed in CSA N290.5. The purpose of this system is to address "Station Blackout" (SBO). At Pickering, this is a BDBA involving total loss of all AC power. This imposes requirements on stored	**Compliant**

REDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	water systems for heatsinks with make-up from Emergency Mitigating Equipment (EME) water pumps supplying Boilers. The alternate power required for the SBO is for monitoring and limited control. This power is provided by EME power supplies involving portable power supplies and AC power from diesel generators. These power supplies are detailed in EME guidelines and in [B.24-60] and [B.24-61]. Pickering is compliant with this clause.	
8.10 Control facilities **8.10.1 Main control room** *The design shall provide for a main control room (MCR) from which the plant can be safely operated, and from which measures can be taken to maintain the plant in a safe state or to bring it back into such a state after the onset of AOOs, DBAs or DECs…* *The design of the MCR shall take ergonomic factors into account to provide both physical and visual accessibility to controls and displays, without adverse impact on health and comfort. This includes hardwired display panels as well as computerized displays, with the aim of making these displays as user-friendly as possible.*	Clause 8.10.1 had a RD-337 gap for Darlington [B.24-21] relating to Human Factors and cabling between the MCR and Common Secondary Control Area. Pickering 5-8 and 1,4 comply with all requirements in this clause relating to cabling. Pickering 5-8 has Unit Secondary Control Areas that are Group 2, remote and isolated from the MCR. Pickering 1,4 has remote monitoring and reactor trip capability in the SDSE Instrument Rooms. Similar to Pickering 5-8 the instrumentation and equipment in these rooms is remote from and physically isolated from the MCR. As identified for Clause 7.21 above, there is a gap relating to the systematic application of Human Factors Engineering principles into the original Pickering plant design.	**PSR2 REGDOC-2.5.2 Gap #8** (Human Factors in Design) Safety Factor 1 (Plant Design)
8.10.1.1 Safety parameter display system *The MCR shall contain a safety parameter display system (SPDS) that presents sufficient information on safety-critical parameters for the diagnosis and mitigation of DBAs and DECs.* *The SPDS shall have the following capabilities:* *1. display safety-critical parameters within the full range expected in operational states, DBAs and DECs …*	Both Pickering 5-8 and 1,4 have the equivalent to SPDSs. However, a new requirement relating to DECs qualification has been introduced. The safety parameter display systems (SPDSs) or critical safety parameter monitoring (CSPM) display are not qualified for DECs where there is a total loss of AC power. Further, the CSPM displays have not been qualified for events such as seismic and fire.	**PSR2 REGDOC-2.5.2 Gap #10** (Safety Parameter Display System Qualification for DECs) Safety Factor 1 (Plant Design)

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
The SPDS shall be designed and installed such that the same information is made available in a secure manner to the emergency response facility.	As part of the Fukushima follow-up, instrumentation to support critical parameters required to function for DECs has been evaluated for survivability in [B.24-114]. The instrument loops associated with these parameters have been identified for use in CSPM and BDBA accident procedures. The indications from these loops are not in one central location and, in some cases, require field action (e.g., power) to obtain data. Although this does not fully satisfy the requirements to have these parameters available from a SPDS in the MCR and Secondary Control Area (SCA) (clause below), it is considered to be an acceptable alternative. However, this is a PSR2 gap relating to the new plant requirement to have SPDS that is DEC qualified and with parameters available in the in the MCR and SCA. The CSPM displays are available in the emergency Site Management Center. Therefore, this is a PSR2 gap.	
8.10.2 Secondary control room *The design shall provide an SCR that is physically and electrically separate from the MCR, and from which the plant can be placed and kept in a safe shutdown state when the ability to perform essential safety functions from the MCR is lost…* *The SCR shall be equipped with an SPDS similar to that in the MCR. As a minimum, this display system shall provide the information required to facilitate placing and keeping the plant in a safe shutdown state when the MCR is uninhabitable…*	Clause 8.10.2 had a RD-337 gap for Darlington [B.24-21] relating to fire code compliance and cabling issue. This has been assessed for Pickering and is not a PSR2 gap. Pickering 5-8 has Unit Emergency Control Centers (UECCs) for each unit which are credited to address Common Mode and Harsh Environment events. These rooms are part of the Group 2 safety functions. A high level description of the functions of and controls in the UECCs is included in Section 7.5 of [B.24-55]. There are no SPDS displays in the UECCs. Pickering 1,4 MCRs have been hardened to provide protection for Seismic and Harsh Environment events. Therefore, functional credits associated with these events are addressed from the MCR and via	**Compliant**

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	field actions. The Shutdown System Enhancement Instrument Rooms (SDSE IRs) provide diverse and separate shutdown logic and monitoring capability, independent of the MCR. For events where the MCR is uninhabitable, the SDSE IR, in conjunction with remote field actions (e.g., Steam Reject Valve control), provide equivalent capability to that required for a SCA. In addition, there is a SPDS display in the SDSE IR. Therefore, this clause does not represent a PSR2 gap for Pickering 1,4. Pickering Units 5-8 do have SCAs but there is no SPDS system in them. This issue is included in REGDOC-2.5.2 Clause 8.10.1.1 immediately above.	
8.10.3 Emergency support facilities *The design shall provide for onsite emergency support facilities that are separate from the plant control rooms for use by the technical support staff and emergency support staff in the event of an emergency…* *The design shall ensure that the emergency support facilities:* *1. includes provisions to protect occupants over protracted periods from the hazards resulting from DBAs and DECs* *2. is equipped with adequate facilities to allow extended operating periods…*	The Consolidated Nuclear Emergency Plan [B.24-62], establishes and governs the emergency facilities. The EITER program assures that EP provisions are available [B.24-67]. The BDBA standard [B.24-59] provides assurance that procedures and staff are capable of addressing BDBAs. The Emergency Operations Centre (EOC) is in the plant at a location remote from the MCR. There is a Site Management Center (SMC) outside the station boundary in close proximity to the plant. Back-up emergency support facilities are available at Darlington or the CEOF in Whitby. Hence, Pickering is PSR2 compliant.	**Compliant**
8.10.4 Credit for operator action *If operator action is required for actuation of any safety system or safety support system equipment, all of the following requirements shall apply:* *1. there are clear, well-defined, validated, and readily available operating procedures that identify the necessary actions* *2. there is instrumentation in the control rooms to provide clear and unambiguous indication of the necessity for operator action*	Credited operator actions are identified in Section 1 of Part 3 of the Safety Reports [B.24-56], [B.24-57] for Pickering 1,4 and Pickering 5-8 respectively. DBA event based response is per the Abnormal Incidents Manuals (AIM). For less severe events, operators may respond via Annunciation Response Manuals (ARMs) and/or Section 5 of Operating Manuals. All Emergency	**<u>PSR2 REGDOC-2.5.2 Gap #6</u>** (Allowable Times for Crediting On-Site Operator Actions) Safety Factor 1 (Plant Design)

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
3. following indication of the necessity for operator action inside the control rooms, there are at least 30 minutes available before the operator action is required *4. following indication of the necessity for operator action outside the control rooms, there is a minimum of 1 hour available before the operator action is required …* **Guidance** *If operator action is required for actuation of any safety function, other than meeting the requirements of this regulatory document, the analysis should also demonstrate that:* • *there is sufficient time available for the operator to perform the required manual action* *the operator can perform the actions correctly and reliably in the time available*	Operating Procedures in the AIMs are validated. As noted in Clause 7.10 above, the action timing requirements have changed from 15 and 30 min to 30 min and 1 hr. Assessments in the Safety Reports are based on 15 and 30 minutes. Therefore, Pickering is not compliant with this requirement. This gap has previously been identified against Clause 7.10 above. However, it should be noted that the guidance provides the option to perform an analysis to support an earlier credit. Given that the operator actions have all been validated using a combination of simulator exercises, tabletop walkthroughs, drills and testing, the existing operator action time credits are well supported. Therefore, it may be possible to reclassify aspects of this gap as an acceptable deviation.	
8.11 Waste treatment and control *The design shall include provisions to treat liquid and gaseous effluents in a manner that will keep the quantities and concentrations of discharged contaminants within prescribed limits, and that will support application of the ALARA principle.*	A high level description of Pickering waste treatment and control is provided in Section 13 of Part 2 of the Safety Report [B.24-54], [B.24-55] for Pickering 1,4 and Pickering 5-8 respectively. Reference [B.24-115] establishes the program that manages all aspects of radiological impact on the environment. A separate PSR2 Safety Factor review is performed for Radiological Impact on the Environment, Safety Factor 14 per [B.24-9]. Additionally, PSR2 reviews of the following standards relating to radioactive emission control and ALARA have been performed: • CNSC G-129 (2004), "Keeping Radiation Exposures and Doses 'As Low As Reasonably Achievable (ALARA)'" • CSA N288.1-14, "Guidelines for Calculating Derived Release Limits for Radioactive Material Airborne	**Compliant** Addressed in PSR2 Safety Factor and other PSR2 code reviews

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	and Liquid Effluents for Normal Operation of Nuclear Facilities" • CSA N288.4-10, "Environmental Monitoring Program at Class I Nuclear Facilities and Uranium Mines and Mills" • CSA N288.5-11, "Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills" • CSA N288.6-12, "Environment Risk Assessments at Class I Nuclear Facilities and Uranium Mines and Mills" • CSA N288.3.4-13, "Performance Testing of Nuclear Air-Cleaning Systems at Nuclear Facilities" Pickering is compliant with this requirement.	
8.11.1 Control of liquid releases to the environment *The design shall include provisions to treat liquid and gaseous effluents in a manner that will keep the quantities and concentrations of discharged contaminants within prescribed limits, and that will support application of the ALARA principle.*	Addressed in clause immediately above.	**Compliant** Addressed in PSR2 Safety Factor and other PSR2 code reviews
8.11.2 Control of airborne material within the plant The clause details requirements for controlling airborne radioactive contamination within the plant. Additionally it details requirements for establishing radiological zoning.	Clause 8.11.2 had a RD-337 gap for Darlington [B.24-21] relating to an Off-gas management system. However, as addressed in Section B.24.2.1 above, this is not a gap for Pickering. A description of the ventilation and filtration systems is provided in Section 11 of Part 2 of the Safety Report [B.24-54], [B.24-55] for Pickering 1,4 and Pickering 5-8 respectively. The overriding program for control of radiation within the plant is the "Radiation Protection Requirements" [B.24-116]. The control of radioactive contamination in the plant is fully	**Compliant** Addressed in PSR2 Safety Factor and other PSR2 code reviews

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	addressed in PSR2 Safety Factor 15 Radiation Protection [B.24-9].	
8.11.3 Control of gaseous release to the environment The clause details requirements for control of radioactive gas emissions and for removing radioactivity from release paths to atmosphere.	A description of the ventilation and filtration systems is provided in Section 11 of Part 2 of the Safety Report [B.24-54], [B.24-55] for Pickering 1,4 and Pickering 5-8 respectively. All elements of this clause are addressed in the clause 8.11 review above.	**Compliant** Addressed in PSR2 Safety Factor and other PSR2 code reviews
8.12 Fuel handling and storage *There shall be barriers to prevent the insertion of incorrect, defective or damaged fuel into the reactor.* *There shall be provisions to prevent contamination of the fuel and the reactor.* *The design shall meet the requirements found in CNSC RD-327, Nuclear Criticality Safety.*	A high level description of the Pickering fuel handling process and systems is included in Section 10 of Part 2 of the Safety Report [B.24-54], [B.24-55] for Pickering 1,4 and Pickering 5-8 respectively. The introduction of RD-327, "Nuclear Criticality Safety", is a new requirement. However, given that Pickering uses natural uranium fuel, criticality events while handling new and used fuel outside the reactor are not credible. Pickering is compliant with these requirements.	**Compliant**
8.12.1 Handling and storage of non-irradiated fuel	Addressed in Clause 8.12 above.	**Compliant**
8.12.2 Handling and storage of irradiated fuel *The design of the handling and storage systems for irradiated fuel shall:* *1. ensure nuclear criticality safety* *2. permit adequate heat removal in operational states, DBAs and DECs* *3. permit inspection of irradiated fuel…* *The design of irradiated fuel storage pools shall include means for preventing the uncovering of fuel in the pool in operational states, DBAs and DECs.* *The design for a water pool used for fuel storage shall include provisions for DECs by:* *1. ensuring that boiling in the pool does not result in structural damage* *2. providing temporary connections to enable the refill of the pool using temporary supplies*	The handling of used fuel is addressed in Clause 8.12 above. DEC is a new addition. However EME and SAMG response addresses loss of cooling and failures in the irradiated fuel bays per [B.24-12] and [B.24-53]. This addresses all DEC requirements. Failure of fuel in fueling machines or transfer mechanisms for DECs is bounded by DBA analysis already in the Safety Reports, Appendix 1 of [B.24-56] and [B.24-57], for Pickering 1,4 and Pickering 5-8 respectively.	**Compliant**

REGDOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
3. providing temporary connections to heat removal systems for power and cooling water *4. providing hydrogen mitigation in the spent fuel pool area* *5. ensuring that severe accident management actions related to the spent fuel pool can be carried out*	Pickering is compliant with these requirements.	
8.12.3 Detection of failed fuel *The design shall provide a means for allowing reliable detection of fuel defects in the reactor, and the subsequent removal of failed fuel, if action levels are exceeded.*	The presence of failed fuel is usually detected by chemistry sampling. Once elevated Iodine samples are detected, a review of fueling activities and transients is initiated. The "Reactor Physics Fuel Management and Core Surveillance" manual [B.24-117] details the systematic process for locating and removing failed/defective fuel. Pickering is compliant with these requirements.	**Compliant**
8.13 Radiation Protection *The design and layout of the plant shall make suitable provision to minimize exposure and contamination from all sources. This shall include the adequate design of SSCs to:* *1. control access to the plant* *2. minimize exposure during maintenance and inspection* *3. provide shielding from direct and scattered radiation* *4. provide ventilation and filtering to control airborne radioactive materials* *5. limit the activation of corrosion products by proper specification of materials* *6. minimize the spread of active material* *7. monitor radiation levels* *8. provide suitable decontamination facilities…*	A description of the Radiation Protection provisions is provided in Section 12 of Part 2 of the Safety Report [B.24-54], [B.24-55] for Pickering 1,4 and Pickering 5-8 respectively. The overriding program for control of radiation within the plant is the "Radiation Protection Requirements" [B.24-116]. The control of radioactive contamination in the plant is fully addressed in PSR2 Safety Factor 15 Radiation Protection. This addresses the heading and all sub-clauses except for 8.13.3 which is addressed below.	**Compliant** Addressed in PSR2 Safety Factor and other PSR2 code reviews
8.13.3 Radiation monitoring *Equipment shall be provided to ensure that there is adequate radiation monitoring in operational states, DBAs and DECs.* *Stationary alarming dose rate meters shall be provided:* *1. for monitoring the local radiation dose rate at places routinely occupied by operating personnel*	Pickering has alarming radiation monitoring equipment distributed within and outside containment in areas where there is a risk of elevated radiation. The locations of detectors, detection ranges and alarm levels are documented in [B.24-118] and [B.24-119]. The DECs requirement is a new addition that was not previously included in RD-337.	**Compliant**

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
2. where the changes in radiation levels may be such that access may be limited for periods of time *3. to indicate, automatically and in real-time, the general radiation level at appropriate locations in operational states, DBAs and DECs* *4. to give sufficient information in the control room or at the appropriate control location for operational states, DBAs and DECs, to enable plant personnel to initiate corrective actions when necessary.*	Pickering has installed an Automated Source Term Gamma Monitoring System (ASTGMS) for emergency and source term radiation monitoring. Its availability is managed via the EITER program [B.24-67]. ASTGMS is not qualified for all DECs in the event that power is lost. In the absence of ASTGMS availability, the Critical Safety Parameter Monitoring AIM provides a list of alternate indications, including manual radiation measurements. Given that there are alternate provisions available, this issue has low safety significance and is not considered to be a PSR2 gap.	
9. Safety Analysis **9.1 General** *A safety analysis of the plant design shall include hazard analysis, deterministic safety analysis, and probabilistic safety assessment (PSA) techniques. The safety analysis shall demonstrate achievement of all levels of defence in depth, and confirm that the design is capable of meeting the applicable expectations, dose acceptance criteria and safety goals…* *Radioactive sources other than the reactor core, such as the spent fuel pool and fuel handling systems, shall be considered. Impacts for multiple units at a site if applicable, shall be included.* *The first step of the safety analysis shall be to identify PIEs using a systematic methodology, such as failure modes and effects analysis. Both direct and indirect events shall be considered in PIE identification. Requirements and guidance for identification of PIEs is given in section 7.4 of this document.*	This clause identifies the high level requirements for hazard analysis, deterministic safety analysis, and probabilistic safety assessment, with which Pickering is in alignment. The second paragraph is new and introduces irradiated fuel bay (IFB) issues. PIEs have been identified consistent with REGDOCs-2.4.1 and 2.4.2, and identified in both the PSA initiating event tables and in the DSAs for Pickering [B.24-56] and [B.24-57]. IFB failures are addressed in the DSA and in BDBA assessments and response per [B.24-53]. Pickering is compliant with these requirements.	**Compliant**
9.2 Analysis objectives *The final safety analysis shall: …* *2. account for postulated aging effects on SSCs important to safety…* *8. demonstrate that the design incorporates sufficient safety margins*	This clause states high level objectives. Darlington was compliant with these requirements for RD-337 [B.24-21]. Given the generic application of safety analysis methodology for both Darlington and Pickering, the Darlington compliance assessment is applicable to PSR2. Items 2 and 8 are new additions. These are both addressed in the	Addressed in PSR2 Safety Factor and other PSR2 code reviews. PSR2 REGDOC-2.4.1 Gap.

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
	assessment of PSR2 for REGDOC-2.4.1 [B.24-14], and in the PSR2 Safety Factor 5 review for Deterministic Safety Analysis.	
Guidance The *Class I Nuclear Facilities Regulations* requires a preliminary safety analysis report demonstrating the adequacy of the NPP design to be submitted in support of an application for a licence to construct a Class I nuclear facility. A final safety analysis report demonstrating the adequacy of the design is required for an application for a licence to operate a Class I nuclear facility.	This is a new requirement. Final Safety Analysis Reports (FSARs) are not used for existing plants. The applicable constituents of the FSAR are referenced in the Licence [B.24-2] and the LCH [B.24-3], and include the OP&Ps, SOE, DSA, PSA, Radiation Protection, etc. Therefore, Pickering is compliant with the intent of this requirement.	**Compliant**
9.3 Hazard analysis **Guidance** The objective of the hazard analysis is to determine the adequacy of protection of the NPP against internal and external hazards, while taking into account the plant design and site characteristics. To ensure the availability of required safety functions and operator actions, all the SSCs important to safety (including the main control room, secondary control room and emergency support facilities) should be adequately protected against relevant internal and external hazards…	This is a new requirement. Hazard Analysis is addressed in the PSR2 Safety Factor 7 report. This clause required there to be a specific Hazard Analysis report for the plant. The required contents of the report are addressed in various other reports for Pickering such as the Safety Report, Risk Assessments, Fire Safe Shutdown Analysis, Seismic Margin Assessment, etc. It is concluded that Pickering is compliant with the intent of this clause.	Addressed in PSR2 Safety Factor review.
9.4 Deterministic safety analysis The deterministic safety analysis shall be conducted in accordance with the requirements specified in CNSC regulatory document REGDOC-2.4.1, *Deterministic Safety Analysis*.	Reference to REGDOC-2.4.1 [B.24-14] is a new addition. A specific code review is being performed for this standard as part of PSR2.	Addressed in PSR2 code reviews.
9.5 Probabilistic safety assessment The probabilistic safety assessment shall be conducted in accordance with the requirements specified in CNSC REGDOC-2.4.2, *Probabilistic Safety Assessment (PSA) for Nuclear Power Plants*.	Reference to REGDOC-2.4.2 [B.24-15] is a new addition. A specific code review is being performed for this standard as part of PSR2.	Addressed in PSR2 code review.
10.1 Design for environmental protection **Guidance** The design should incorporate the "best available technology and techniques economically achievable" (BATEA) principle for aspects of the design related to environmental protection.	This is a new requirement in REGDOC-2.5.2. However, environmental requirements with no potential radiological implications are not part of PSR2 scope. Per the PSR Basis Document [B.24-9], Safety Factor 14 only deals with radiological impact on the environment.	n/a

REDGOC-2.5.2 Clauses (text in italics is verbatim from the code)	**PSR2 Review**	**Gap or Compliance?**
10.2 Release of nuclear and hazardous substance Pollution prevention principles shall be applied when considering the technological design options for cooling water systems, in order to minimize adverse environmental impact.	See clause immediately above. For radiological impact on the environment refer to PSR2 Safety Factor 14 review and assessment under clause 8.11 above.	See Clause 10.1 above
11. Alternative Approaches The requirements in this regulatory document are intended to be technology neutral for watercooled reactor designs. It is recognized that specific technologies may use alternative approaches…	For information, only.	n/a
Appendix A: Structural Analysis of Containment Structures	New appendix Appendix A was added to outline acceptance criteria when performing structural analysis of containment structures for robustness against malevolent acts. Treatment of malevolent acts is not within the PSR2 review scope.	n/a

B.24.3 Compliance Summary for Pickering PSR2

There are ten PSR2 CNSC REGDOC-2.5.2 (2014) gaps. The gaps and their associated Safety Factor are identified below:

1. Safety Factor 5 (Deterministic Safety Analysis) – Clauses 4.2.1, 6.4 and 7.3 of REGDOC-2.5.2 introduce new requirements and limits for Anticipated Operational Occurrences (AOOs), Design Basis Accidents (DBAs) and Beyond Design Basis Accidents (BDBAs) and include specific dose limits for AOOs and DBAs. Current Pickering Safety Report analyses do not identify and classify events into these categories. Dose limits currently used in Pickering are aligned with the single failure / dual failure limits in accordance with the Pickering Licence Conditions Handbook. This issue has therefore been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation.

2. Safety Factor 6 (Probabilistic Safety Assessment) – Clause 4.2.2 of REGDOC-2.5.2 introduces new requirements and limits for probabilistic analysis risk limits, such as a core damage frequency limit of $<10^{-5}$ yrs/yr. It has not been demonstrated that these requirements can be achieved. Therefore, this has been identified as a PSR2 gap.

3. Safety Factor 1 (Plant Design) – Containment Leak Tightness for Design Extension Conditions (DECs): Clauses 7.3 and 8.6.12 of REGDOC-2.5.2 require containment to provide a leak tight barrier following DECs with severe core damage for a period sufficient to implement off-site emergency measures. REGDOC-2.5.2 guidance suggests this period be at least 24 hours. Such a requirement does not exist in Beyond Design Basis Accident (BDBA)/Severe Accident (SA) mitigation, so this represents a PSR2 gap.

4. Safety Factor 1 (Plant Design) – On-Demand Reliability of Safety Systems: Clause 7.6 of REGDOC-2.5.2 requires all Structures, Systems, and Components (SSCs) important to safety (SIS) to meet an on-demand failure rate of $<10^{-3}$ yrs/yr. This requirement is not met for several systems including Pickering 1,4 Emergency Coolant Injection (ECI) and is therefore identified as a PSR2 gap.

5. Safety Factor 1 (Plant Design) – Sharing of Safety Systems and Turbine Hall: Clause 7.6.5 of REGDOC-2.5.2 has a new requirement that sharing of safety systems and the turbine generator building not be permitted. Pickering Units share Emergency Coolant Injection (ECI) and Negative Pressure Containment (NPC), as well as the turbine hall; therefore, this has been identified as a PSR2 gap.

6. Safety Factor 1 (Plant Design) – Allowable Times for Crediting On-Site Operator Actions: Clauses 7.10 and 8.10.4 of REGDOC-2.5.2 establish new time limits for crediting operator actions, i.e., 30 minutes for Main Control Room (MCR) actions and 1 hour for field actions. Pickering NGS has not demonstrated that deterministic safety analysis consequences are acceptable if MCR and field action are not credited for these times respectively. Therefore, this has been identified as a PSR2 gap.

7. Safety Factor 1 (Plant Design) – Seismic Qualification and Design: Clause 7.13.1 of REGDOC-2.5.2 requires that Beyond Design Basis (BDB) Earthquake seismic margin be a factor of 1.67 beyond that required for the new plant Design Basis Earthquake (DBE). Fragility evaluations were completed for seismic mitigating Structures, Systems and Components (SSCs), however, based on available information it could not be confirmed that the new plant BDB Earthquake margin of 1.67 would be achieved. Therefore, this has been identified as a PSR2 gap.

8. Safety Factor 1 (Plant Design) – Human Factors in Design: Clauses 7.21 and 8.10.1 of REGDOC-2.5.2 introduce new requirements for the systematic application of Human Factors Engineering (HFE) principles to plant design. Many years of safe and reliable operating experience indicate that the design and processes for integration of human interactions with the plant were and remain robust. However, Pickering plant design predates the current requirements for incorporating HFE into the design and the existing plant has not been systematically demonstrated to meet the requirements for a new plant. Therefore, this has been identified as a PSR2 gap.

9. Safety Factor 1 (Plant Design) – Detection/Isolation of Emergency Coolant Injection (ECI) Heat Exchanger Tube Leak: Clause 8.5 of REGDOC-2.5.2 requires ECI recovery heat exchanger tube leak detection capability. Pickering Units 5-8 ECI recovery heat exchangers do not have leak detection capability on the cooling water side. Therefore, this has been identified as a PSR2 gap.

10. Safety Factor 1 (Plant Design) – Safety Parameter Display System Qualification for Design Extension Conditions (DECs): Clause 8.10.1.1 of REGDOC-2.5.2 requires the Main Control Room (MCR) to contain a Safety Parameter Display System (SPDS) that presents sufficient information on safety-critical parameters for the diagnosis and mitigation of Design Basis Accidents (DBAs) and DECs. The SPDSs are to be qualified for DEC and have parameters available in both the MCR and Secondary Control Areas (SCA), per Clause 8.10.2. Pickering SPDSs are not Review Level Condition (RLC) qualified or available in all locations. As part of the Fukushima follow-up, instrumentation to support critical parameters required to function for DECs has been evaluated for survivability. The instrument loops associated with these parameters have been identified for use in Critical Safety Parameter Monitoring (CSPM) and Beyond Design Basis Accident (BDBA) procedures. However, the indications from these loops are not in one central location and, in some cases, require field action (e.g., power) to obtain data. This does not fully satisfy the requirements to have these parameters available from a SPDS in the MCR and SCA. Therefore, this has been identified as a PSR2 gap relating to the new plant requirement to have SPDS that is DEC qualified and with parameters available in the MCR and SCA.

B.25 CNSC G-144 (2006), "Trip Parameter Acceptance Criteria for the Safety Analysis of CANDU Nuclear Power Plants"

B.25.1 Background

The following paraphrased from the purpose and scope of CNSC G-144 (2006) [B.25-1] provides a brief overview of the purpose of this Regulatory Guide and the requirements expressed therein:

> *The purpose of G-144 is to provide guidance to licensees who operate CANDU nuclear power plants regarding reactor trip parameters that will preclude direct or consequential failures of reactor fuel or reactor pressure tubes.*
>
> *G-144 outlines the criteria that the selected reactor trip parameters for the plant are expected to meet, under all postulated design basis accidents other than the following:*
>
> 1. *Large loss of coolant accidents (LLOCA);*
> 2. *Very slow loss of reactivity control (VSLORC) accidents;*
> 3. *Fast loss of reactivity control (FLORC) accidents;*
> 4. *Fuelling machine accidents;*
> 5. *Single channel accidents; and*
> 6. *Accidents in the spent fuel bay.*

G-144 is relevant to Safety Factor 5 (Deterministic Safety Analysis). The latest version is G-144 (2006) [B.25-1]. G-144 is not identified in Appendix C or E of the R04 Licence Conditions Handbook [B.25-2], meaning it is not in Pickering PROL 48.02/2018 or cited by the CNSC as "Guidance and Criteria".

The CNSC recently communicated in Reference [B.25-3] plans to retire the Code on the basis that the acceptance criteria as outlined in G-144 are no longer applicable and have been replaced by a new set of acceptance criteria documented in COG Report COG-13-9035 R00, "Derived Acceptance Criteria For Deterministic Safety Analysis" [B.25-4].

The results of PSR1 G-144 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)) have been assessed for applicability to PSR2 in Section B.25.2. As identified in Reference [B.25-5], the Pickering PSR2 review of CNSC G-144 (2006) is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.

- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.25.2 Compliance Assessment for Pickering PSR2

B.25.2.1 Application of PSR1 Reviews

The versions of G-144 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

The Pickering B ISR was performed using the latest version of the guide, i.e., G-144 (2006) [B.25-1] and was documented in OPG Report NK30-REP-03680-00005 R000 [B.25-6]. Reference [B.25-6] documented a clause-by-clause review of G-144 (2006) for Safety Factor 5. The review identified five cases where compliance was deemed to be an Acceptable Deviation. The Acceptable Deviations were related to dual trip parameter coverage, no dry-out criterion for the first trip, allowable duration of post dry-out operation for the second trip and interpretation of the acceptance criteria relating to acceptable duration of post dry-out operation.

Reference [B.25-6] identified that Pickering B compared favorably against the newest CANDU stations in terms of trip effectiveness. It was noted that the G-144 criteria were surrogates to the real criteria (fuel and channel integrity) and are conservative with respect to the actual safety criteria. Further, it was noted that in many instances of deviations there are either:

- A large number of redundant instruments that, while considered single parameter coverage, have in fact a large amount of redundancy (e.g., the large number of NOP detectors available in each logic channel during a slow Loss of Regulation event); or

- Trips are available, but they come in either slightly after dryout, or slightly beyond the 600°C/60 second criteria specified in G-144.

Based on the above findings, which are not impacted by operation beyond 2020, there are no gaps for PSR2 resulting from the Pickering B ISR reviews of G-144.

Pickering Units 1,4

G-144 had not yet been issued at the time of Pickering A Return to Service and as such a code review was not performed. However, the compliance assessment performed for the Pickering B ISR is not specific to any design differences which exist between Pickering Units 5-8 and Pickering Units 1,4, and as such, the findings are applicable to Pickering Units 1,4.

Darlington NGS

The Darlington ISR was performed using the latest version of the guide, i.e., G-144 (2006) [B.25-1] and was documented in OPG Report NK38-REP-03680-10015 R000 [B.25-7]. Reference [B.25-7] documented a high-level intent review of G-144 (2006) for Safety Factor 5. One gap in compliance was identified with Clause 5.0, which provides the specifics of the trip parameter effectiveness acceptance criteria. This gap was addressed through the industry initiative discussed in Section B.25.2.2.

B.25.2.2 Application of Post-PSR1 Reviews

Subsequent to completion of the Darlington ISR, the Industry, with CNSC input, convened work through COG associated with Safety Report analysis acceptance criteria. As part of that work, an Independent Technical Panel on trip effectiveness acceptance criteria was established to review the experimental database and provide recommendations on fuel and fuel channel integrity acceptance criteria for application to accidents associated with regulatory guide G-144 (2006). COG-10-2010, "ITP Recommendations for the CANDU Trip Effectiveness Acceptance Criteria" [B.25-8] was issued with recommendations for acceptance criteria. COG-13-9035 [B.25-4] documents fuel and fuel channel derived acceptance criteria and technical bases for slow events that are intended to replace the requirements of G-144 (2006). The CNSC staff completed their review of the technical basis for the new set of acceptance criteria documented in COG-13-9035 and concluded that the new criteria were developed in accordance with CNSC Document REGDOC-2.4.1, "Deterministic Safety Analysis" [B.25-9] and on that basis identified that G-144 is no longer applicable and will be retired.

COG-13-9035 [B.25-4] outlines the implementation processes for the new criteria as agreed to by the Industry and the CNSC. The derived acceptance criteria outlined in COG-13-9035 for slow events are less restrictive than those outlined in the current Pickering 1,4 and Pickering 5-8 Safety Reports ([B.25-10], [B.25-11]), providing confidence that the derived acceptance criteria documented in COG-13-9035 will not adversely impact on existing margins as demonstrated in the Safety Reports.

In Reference [B.25-12], OPG communicated to the CNSC that going forward, OPG will no longer provide analysis results for comparison against G-144 screening criteria, and instead will use the derived acceptance criteria outlined in COG-13-9035 [B.25-4]. On the basis of the Industry work undertaken to replace the requirements of G-144 (2006) with the derived acceptance criteria outlined in COG-13-9035, per Reference [B.25-3], the CNSC plans to retire G-144 and will update the Compliance Verification Criteria in the Pickering Licence Conditions Handbook to include COG-13-9035 under Licence Condition 5.1, Safety Analysis.

B.25.3 Compliance Summary for Pickering PSR2

There are no PSR2 gaps for CNSC G-144 (2006) [B.25-1]. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with G-144 (2006).

B.26 CNSC G-149 (2000), "Computer Programs Used In Design and Safety Analyses of Nuclear Power Plants and Research Reactors"

B.26.1 Background

The following paraphrased from the purpose and scope of CNSC G-149 (2000) [B.26-1] provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The purpose of G-149 is to provide guidance to licensees involved in the development, maintenance and use of computer programs used in the design and safety analysis of nuclear power plants and research reactors so that a high degree of confidence may be placed in both the programs and the results of their application.*
>
> *G-149 applies to licensees whose computer programs are used in:*
>
> - *designing or supporting the design of a nuclear power plant or research reactor*
> - *analyzing operational transients, incidents or accidents.*
>
> *G-149 does not apply to operational control systems software. For computer programs developed before the effective date of this regulatory guide, the degree of applicability is specified in section 8 of this guide.*

G-149 is relevant to Safety Factors 1 (Plant Design), 5 (Deterministic Safety Analysis), 6 (Probabilistic Safety Assessment) and 7 (Hazard Analysis). G-149 is not identified in Appendix C or E of the R04 Licence Conditions Handbook [B.26-2], meaning it is not in Pickering PROL 48.02/2018 or cited by the CNSC as "Guidance and Criteria". CNSC G-149 (2000) is the first edition of this Regulatory Guide.

The results of PSR1 G-149 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Review (ISRs)) have been assessed for applicability to PSR2 in Section B.26.2. As identified in Reference [B.26-3], the Pickering PSR2 review of CNSC G-149 (2000) is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- <u>Compliance:</u> Compliance indicates that the change in the safety requirement, per the topical review, is met.
- <u>Gap</u>: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.26.2 Compliance Review History

B.26.2.1 Application of PSR1 Reviews

The versions of G-149 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

<u>Pickering Units 5-8</u>

A clause-by-clause review of CNSC G-149 (2000) was performed at a high level as part of the Pickering B ISR [B.26-4] for the Deterministic, Probabilistic Safety Analysis and Hazard Analysis Safety Factors (Safety Factors 5, 6, and 7). The review of the guide performed as part of the Pickering B ISR was a high level review which confirmed that OPG's governance and processes adequately addressed the intent of the guide.

OPG first implemented its software quality assurance programs for Nuclear Safety Analysis based on the requirements of CSA Standard N286.7-94, well in advance of G-149 being issued in 2000. Reference [B.26-4] identifies that, in general, the content and definitions of G-149 are very similar to CSA N286.7-99, i.e., the version of CSA N286.7 reviewed as part of the Pickering B ISR. As such, demonstrating Direct Compliance with CSA N286.7-99, which was the case, was sufficient to meet the intent of G-149. Reference [B.26-4] identified one notable exception between G-149 and CSA N286.7-99 which related to Clause 8.0 of G-149. Clause 8.0 of G-149 pertains to *Existing Computer Codes*. Reference [B.26-4] identifies that Generic Action Item (GAI) 98G02 *Validation of Computer Programs used in Safety Analysis of Power Reactors* and its closure were considered to have met the intent of Clause 8.0 as it pertains to legacy codes. On that basis, the Pickering B ISR found that OPG software governance was in Indirect Compliance with G-149.

The review performed as part of the Pickering B ISR did not identify any gaps against G-149. There are therefore no PSR2 gaps which result from the Pickering B ISR.

<u>Pickering Units 1,4</u>

CNSC G-149 was not included in the list of codes and standards reviewed as part of Pickering A Return to Service. The subsequent clause-by-clause review of CNSC G-149 against OPG software governance that was performed as part of the Pickering B ISR [B.26-4] identified no gaps. Since the review was performed against relevant OPG governance, the conclusions of Reference [B.26-4] are considered equally applicable to Pickering Units 1,4 and Units 5-8. Further, as discussed below, findings from the Darlington ISR are programmatic and applicable to Pickering NGs.

Darlington NGS

OPG Report NK38-REP-03680-10016 R000 [B.26-5] documents a high level review of OPG software governance that was performed against the requirements of Regulatory Guide G-149 (2000) as part of the Darlington ISR. The review was conducted by comparing the requirements of G-149 against OPG software quality assurance governance. The OPG software governance was found to be largely compliant with G-149 (2000), as discussed below.

Reference [B.26-5] notes that early versions of CSA N286.7 contained a number of clauses that required interpretation or expansion to be implemented for which complete guidance was not provided, and which the CSA N286.0 series allowed for a graded interpretation. Consequently, COG Guideline 153-507230-COG-001 R0, "Guideline for the Application of CSA N286.7" [B.26-6] was created by a collaborative industry effort to provide guidance to assist owner organizations and participants in preparing and implementing software quality assurance processes that comply with CSA N286.7. Reference [B.26-5] notes that the COG guideline forms the main basis for OPG Standard N-STD-MP-0008, "Development, Qualification and Use of Scientific, Engineering and Safety Analysis Software" [B.26-7], and as such, its concepts are reflected throughout the OPG software governance. G-149 predates the COG Guideline (Reference [B.26-6]) and reflects the CNSC interpretation of CSA N286.7 at the time of issuance of G-149.

The Darlington ISR found that the OPG Software Quality Assurance is largely compliant with the Regulatory Guide G-149. However, gaps were found to exist in the level of detail of specification for certain activities:

- The relationships between development phases (input and outputs) are not explicitly specified in the OPG software governance. However, these relationships are logical and intrinsic to the development of computer codes, and are likely understood by code developers and testers.

- The OPG software governance does not contain an explicit requirement to place coding produced during the development phase under configuration management. This is not a significant gap as test output with the exception of that arising from regression analysis is ephemeral. Regression test results are necessarily placed under configuration management as they must be available for comparison with the results obtained with a new code version.

- The OPG software governance does not contain an explicit requirement to perform a design review.

The requirements from G-149 that give rise to these gaps are not reflected in CSA N286.7-99 (i.e., the version of CSA N286.7 reviewed as part of the Darlington ISR). Furthermore, Reference [B.26-5] concluded that the gaps arise from an over-specification of detail for certain processes that have an inherent logic that would necessarily be executed through compliance with the OPG software governance. Since OPG software governance was found to be fully compliant with the version of N286.7 reviewed as part of the Darlington ISR, these gaps were not considered to be significant. As noted in Reference [B.26-8], these gaps were identified as Acceptable Deviations under Issue D146 of the Darlington ISR. CNSC acceptance of these gaps as Acceptable Deviations was documented in Reference [B.26-9]. The results of the Darlington ISR from the perspective of G-149 are considered applicable to Pickering Units 1,4 and 5-8, given that the assessment was performed against OPG governance applicable to all of the OPG Nuclear fleet. Hence, there are no PSR2 gaps which result from the Darlington ISR.

B.26.2.2 Application of Post-PSR1 Reviews

G-149 has not been revised since the PSR1 G-149 reviews (Pickering B and Darlington ISRs) were completed and there have been no additional compliance assessments completed since the PSR1 G-149 reviews outlined in Section B.26.2.1 were undertaken. The results of the PSR1 G-149 reviews identified no gaps as the requirements of G-149 are built into existing OPG software governance. Hence, no PSR2 gaps are identified against G-149.

B.26.3 Compliance Summary for PSR2

There are no PSR2 gaps for CNSC G-149 (2000) [B.26-1]. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with G-149 (2000).

B.27 CNSC R-77 (1987), "Overpressure Protection Requirements for Primary Heat Transport Systems in CANDU Power Reactors Fitted With Two Shutdown Systems"

B.27.1 Background

The following paraphrased from the introduction of CNSC Regulatory Document R-77 (1987) [B.27-1] provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The overpressure protection requirements of Article NB 7000 of Section III of the American Society of Mechanical Engineers Boiler and Pressure Vessel Code (ASME Code) are incorporated in the National Standard of Canada N285.1. These requirements do not refer to a particular nuclear system design. This is recognized in paragraphs NCA-2141 and NB-7I20 of the ASME Code which make reference to the requirements of the appropriate regulatory authority for guidance.*
>
> *For CANDU power reactors fitted with two shutdown systems, some guidance is given in the Atomic Energy Control Board (AECB) Regulatory Document R-10, but this does not address overpressure protection as a specific topic and further clarification is required. This document seeks to provide such clarification.*

CNSC R-77 (1987) [B.27-1] is applicable to Safety Factor 1 (Plant Design).

Compliance with CNSC R-77 is not currently a licence requirement for Pickering NGS (in accordance with PROL 48.02/2018) per the R04 Pickering Licence Conditions Handbook [B.27-2].

This regulatory document is no longer available. The content of R-77 [B.27-1] has been incorporated into Section 7.6 of N285.0-12.

The results of PSR1 CNSC R-77 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.27.2. As identified in Reference [B.27-3], the Pickering PSR2 review of CNSC R-77 (1987) is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.
- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.27.2 Compliance Assessment for Pickering PSR2

B.27.2.1 Application of PSR1 Reviews

The versions of R-77 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

A clause-by-clause review against R-77 was performed and documented in report NK30-REP-03680-00001 R000 [B.27-4] as part of the Pickering B ISR Plant Design Safety Factor. The objective of this review was to complete a clause-by-clause review of relevant sections of CNSC R-77, to assess whether the design requirements in CNSC R-77 are covered by design requirements in CSA Standard N285.0 (the PROL requires compliance with N285.0). This approach was taken since CNSC R-77 contains upper tier design requirements for the design of the Primary Heat Transport and Safety Systems and therefore it is sufficient to demonstrate that the design requirements contained in R-77 are covered by the design requirements in CSA N285.0. Compliance with CSA N285.0 was demonstrated in a separate section of Reference [B.27-4].

The Pickering B ISR assessment concluded that all of the design requirements contained in R-77, except one clause, are covered by the design requirements in CSA N285.0. The one exception on Clause 3.6 states:

> *In a case where only one trip parameter is installed in the second shutdown system, this trip parameter may be credited.*

The report states that although Pickering B is in compliance with this clause, it is recommended that CSA N285.0 be modified to include this clause. This has since been addressed in Clause 7.6.2.3 (c) of N285.0 [B.27-5]. There is no PSR2 gap associated with this issue.

The report also documented one Acceptable Deviation, on Clause 3.1 addressing Allowable Service Conditions. It specifies events to analyze based on their probability of occurrence. The report describes that since R-77 was not in place at the time of the issuance of the first Pickering B Operating Licence, the Safety Report used the Siting Guide rules, which are consistent with the intent of those specified in R-77. This rationale remains valid and is not affected by Pickering operation beyond 2020. The Pickering Units 1,4 and 5-8 Safety Reports [B.27-6], [B.27-7] demonstrate that for Design Basis Accidents resulting in Heat Transport System (HTS) overpressure, e.g. a loss of Class IV power, peak stresses are below those allowed for the assigned ASME service level consistent with R-77. Therefore, there is no PSR2 gap associated with this issue.

Pickering Units 1,4

As part of Pickering Units 1,4 Return to Service (PARTS), code reviews were conducted. The main submission for PARTS [B.27-8] committed to perform a review of R-77 [B.27-1]. This review was completed in AECL Report, "Review of Pickering A Design Against Current Codes and Standards" [B.27-9].

The review demonstrated that Pickering Units 1,4 comply with the requirements of R-77. The report also reviewed Safety Report events resulting in HTS overpressure. It concluded that for each of these events, peak stresses are below those allowed for the ASME service level assigned to the event according to R-77 guidelines. These conclusions remain valid per the Safety Report as described above.

Darlington NGS

The Darlington ISR review of R-77 was documented in OPG Report NK38-REP-03680-10019 R000 [B.27-10]. This clause-by-clause review demonstrated that Darlington NGS was compliant with R-77.

B.27.2.2 Application of Post PSR1 Reviews

CNSC Regulatory Document R-77 has not been revised since the initial version issued in 1987. Therefore the conclusions of the Regulatory Document R-77 reviews described in Section B.27.2.1 for Pickering still apply and do not pose any PSR2 gaps.

In addition, per the CSA Impact Statement for the N285.0-12, General Requirements for Pressure-Retaining Systems and Components in CANDU Nuclear Power Plants [B.27-11], the requirements in R-77 were migrated into N285.0-12 (Clause 7.6.2). There has been no change made to these requirements in the latest version, i.e., N285.0-12 including Updates No. 1 and No. 2, per the associated CSA Impact Statement [B.27-12]. Also, the PSR2 assessment of CSA N285.0-12 did not identify any gaps associated with Clause 7.6.2.

Therefore, there are no PSR2 gaps associated with Regulatory Document R-77.

B.27.3 Compliance Summary for Pickering PSR2

There are no PSR2 gaps for CNSC R-77 (1987) [B.27-1]. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with CNSC R-77 (1987).

B.28 CSA N288.2-14, "Guidelines for Calculating Radiological Consequences to the Public from a Release of Airborne Radioactive Material for Nuclear Reactor Accidents"

B.28.1 Background

The following paraphrased from the introduction of CSA N288.2-14 [B.28-1] provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *CSA N288.2 provides guidelines and a methodology for calculating effective doses and thyroid doses to people (either individually or collectively) in the path of airborne radioactive material released from a nuclear facility following a hypothetical accident.*
>
> *The specific radionuclides considered in CSA N288.2 are those associated with substances having the greatest potential for becoming airborne in reactor accidents [e.g., tritium (HTO), noble gases and their daughters (Kr-Rb, Xe-Cs), and radioiodines (I)]; as well as certain radioactive particulates (e.g., Cs, Ru, Sr, Te) that may become airborne under exceptional circumstances.*
>
> *CSA N288.2 focuses on the calculation of radiation doses for:*
>
> > *(a) External exposures from radioactive material in the cloud;*
> >
> > *(b) Internal exposures from inhalation of radioactive material in the cloud and also skin penetration of tritium; and*
> >
> > *(c) External exposures from radionuclides deposited on the ground, during and after passing of the cloud.*

CSA N288.2 is relevant to Safety Factor 5 (Deterministic Safety Analysis). CSA N288.2 is not discussed in the R04 Pickering Licence Conditions Handbook [B.28-2].

CSA N288.2-14 is the second edition of this standard, and supersedes the previous version published in 1991 under the title *Guidelines for Calculating Radiation Doses to the Public from a Release of Airborne Radioactive Material under Hypothetical Accident Conditions in Nuclear Reactors* [B.28-3]. According to the preface of the 2014 edition, it has been updated to reflect current industry practice and new research and analysis methods. Major changes in the 2014 edition are discussed in Section B.28.2.2 below.

The results of PSR1 CSA N288.2 reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.28.2. As identified in Reference [B.28-4], the Pickering PSR2 review of CSA N288.2-14 is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.
- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.28.2 Compliance Assessment for Pickering PSR2

B.28.2.1 Application of PSR1 Reviews

The versions of N288.2 (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

For the Pickering B ISR, a high level review of CSA N288.2-M91 [B.28-3] was conducted in 2007 and included in Appendix E of the Safety Analysis Safety Factor Review Report [B.28-5]. The review concluded that:

> *The OPG methodology is in compliance with the intent of CSA N288.2 (Indirect Compliance).*

There were no ISR gaps identified and no CNSC comments raised regarding the code compliance assessment against N288.2. However, the same report also noted that there was an open Safety Report Update Issue #115 (defined as the need to update the existing dosimetric information in safety analysis) that would be used to track revision of the OPG methodology for calculating radiological doses from airborne releases. Relevant open Safety Report Analysis Issues were taken into account in the development of the Pickering RD-310 Implementation Plan [B.28-6]. As discussed in the PSR2 review of REGDOC-2.4.1, the prioritization of gaps to be addressed as part of the RD-310 Implementation Plan was based in part on the projected end of commercial operations by 2020. These prioritization criteria were carried forward into the REGDOC-2.4.1 Implementation Plan [B.28-7] which superseded the RD-310 Implementation Plan and reconsideration in the context of extended operations beyond 2020 is already addressed by PSR2 REGDOC-2.4.1 Gap #2.

Pickering Units 1,4

CSA N288.2-M91 was not reviewed as part of Pickering A Return-to-Service ISR because it was concluded that the standard "*Pertains mostly to design support analysis*" [B.28-8]. CSA N288.2 is not mentioned in the R04 Pickering Licence Conditions Handbook [B.28-2] or Pickering PROL Renewal Application [B.28-9]. However, as discussed above, the Pickering B ISR reviewed CSA N288.2-M91 and the conclusions of that work are applicable to Pickering Units 1,4 as the same methodology for dose assessment was applied in both Pickering A and B Safety Reports.

Darlington NGS

Compliance with CSA N288.2-M91 (R2008) [B.28-10] was assessed as part of the Darlington ISR in 2011 [B.28-11]. This was a high-level intent review and Darlington was considered compliant with the exception of a gap relating to Clause 6.2.3. Clause 6.2.3 discusses the assessment of the effect associated with the buildup of radionuclides from decay of parents. The review was unable to find documented evidence that analysis had been carried out to explicitly address buildup of progeny from the point of release under accidental conditions.

This Darlington gap was identified as Gap #400 and was addressed under Issue D026 [B.28-12] and summarized in Reference [B.28-13]. The resolution of the gap resulted in it being reclassified as an Acceptable Deviation and concluded it to have low safety significance with no further action required. Given the similarity of dose calculations between Pickering and Darlington, the same conclusion is applicable to Pickering NGS and there is therefore no PSR2 gap.

B.28.2.2 Application of Post-PSR1 Reviews

As discussed in Section B.28.1, CSA N288.2-14 is the second edition of this standard, and supersedes the previous version published in 1991 under the title *Guidelines for Calculating Radiation Doses to the Public from a Release of Airborne Radioactive Material under Hypothetical Accident Conditions in Nuclear Reactors.* According to the preface of the 2014 edition, major changes include [B.28-1]:

> *a) Updating definitions and terminology in accordance with current usage;*
>
> *b) Incorporation of new guidance from relevant national and international publications that address doses from accidental releases (e.g., new ICRP [International Commission on Radiological Protection] guidance on dose coefficients);*
>
> *c) Broadening the applicability to include assessments that are conducted for licensing, emergency planning, or environmental assessment purposes;*
>
> *d) Provision of guidance on consequence assessments for emergency response during a real event;*
>
> *e) Inclusion of all radionuclides that could be released to the atmosphere in a postulated or real accident;*
>
> *f) Allowance for a stochastic treatment of meteorological data in which doses are calculated for many records in the meteorological archives at a given site;*
>
> *g) Discussion of the uncertainty in the dose estimates;*
>
> *h) Provision of guidance on how to obtain the meteorological information required by the models (e.g., stability class) and performance requirements for data measurement;*
>
> *i) Inclusion of health risks resulting from the predicted doses (including organ doses for deterministic effects);*

j) Consideration of approaches to account for time-dependent releases to the environment;

k) Provision of guidance on the location and age of the representative person for whom doses are calculated;

l) Advanced methods for treating the release of tritium;

m) Provision of guidance on how to determine individual doses from stochastic results consistent with regulatory expectations for conservative analysis; and

n) Provision of guidance on the attributes that atmospheric dispersion computer codes should consider for use in the Canadian regulatory context.

As discussed in the Standard, the guidance in the 2014 edition was updated to reflect current industry practice and new research and analysis methods. Further, the Standard states [B.28-1]:

The new edition does not mandate a single approach or code, or provide detailed equations to construct a code. It describes acceptable methods that can be used to calculate the consequences of a nuclear accident. The new edition also identifies acceptable data sources and acceptable methodologies to account for specific effects, and recommends standardized end points for the calculations.

Darlington and Pickering NGS have not completed compliance reviews against the 2014 version of the standard. However, per the COG Research and Development Annual Reporting [B.28-14], Work Package WP 50109 - *Assessment of Impact of Proposed Revision*, the Industry Standard Toolset code ADDAM (Atmospheric Dispersion and Dose Analysis Method) is being evaluated against the 2014 version of the standard. This assessment will determine the extent of code compliance and recommend required changes to the ADDAM code to comply with the N288.2-14 standard.

Updates to deterministic safety analysis are scoped in accordance with REGDOC-2.4.1 [B.28-15]. No plans to systematically update the existing Pickering safety analysis due to changes in N288.2-14 have been identified in the REGDOC-2.4.1 Implementation Plan [B.28-7]. Currently, the only update identified for Pickering is the development of the Common Mode Events Appendices. According to the Technical Basis Document for these new appendices [B.28-16], the ADDAM code discussed above will be used for the atmospheric dispersion and dose calculations.

As captured in PSR2 REGDOC-2.4.1 Gap #2, the scope of the REGDOC-2.4.1 Implementation Plan will be reconsidered to align with Pickering operation beyond 2020. The REGDOC-2.4.1 Implementation Plan update will consider the incremental implications of Pickering operation beyond 2020, including any considerations of N288.2 revisions. This is identified as a PSR2 gap (**PSR2 CSA N288.2-14 Gap #1**). It is being addressed as part of REGDOC-2.4.1 implementation.

B.28.3 Compliance Summary for Pickering PSR2

There is one PSR2 CSA N288.2-14 gap which relates to Safety Factor 5 (Deterministic Safety Analysis):

1. Safety Report upgrades currently underway for Pickering as part of REGDOC-2.4.1 implementation for the period of 2017-2021 will utilize methods consistent with N288.2-14. The REGDOC-2.4.1 Implementation Plan update will consider the incremental implications of Pickering operation beyond 2020, including any considerations of N288.2 revisions. This issue has therefore been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation.

B.29 CSA N290.7-14, "Cyber-Security for Nuclear Power Plants and Small Reactor Facilities"

B.29.1 Background

The following paraphrased from the preface and scope of CSA N290.7-14 (including Errata, January 2015) [B.29-1] provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *CSA N290.7 pertains to the securing of essential computer systems and components against cyber-attacks resulting in loss of availability, degradation or loss of ability to perform their intended function, compromise of their integrity, and loss of confidentiality of their information. CSA N290.7 does not apply to business systems (e.g., work management), and offline engineering systems (e.g., analytical, scientific, and design computer programs as per CSA N286.7).*
>
> *CSA N290.7 addresses cyber security at nuclear power plants and small reactor facilities for the following computer systems and components:*
>
> *a) Systems important to nuclear safety;*
>
> *b) Nuclear security;*
>
> *c) Emergency preparedness;*
>
> *d) Production reliability;*
>
> *e) Safeguards; and*
>
> *f) Auxiliary assets or systems which, if compromised, exploited, or failed, could adversely impact Item (a), (b), (c), (d) or (e).*

CSA N290.7-14 is applicable to Safety Factor 1 (Plant Design).

Compliance with CSA N290.7 is not currently a licence requirement for Pickering NGS (in accordance with PROL 48.02/2018) per the R04 Pickering Licence Conditions Handbook [B.29-2].

CSA N290.7-14 is the first edition of this standard. The Impact statement for public review [B.29-3] identifies the following significant features of this standard:

1. *This new standard establishes:*
    a. *The requirements for cyber security for nuclear power plants and small reactor facilities.*
    b. *The graded assessment of computer systems to determine the applicability of cyber security controls.*

c. *Cyber security throughout a computer system's lifecycle, from conceptual design through installation, commissioning and decommissioning.*

d. *The need to interface with other organizations.*

2. *This standard identifies the purpose and expected outcomes but does not attempt to describe detailed methodology.*

As identified in Reference [B.29-4], the Pickering PSR2 review of CSA N290.7-14 is a High Level review. For a PSR2 High Level review, the degree of conformance with clauses or groups of clauses in the Law, Regulation, Code or Standard is demonstrated by supporting evidence stating whether the intent of the requirements stipulated in the requirement document is met. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the intent of the safety requirement is met.
- Gap: A Gap indicates that the intent of the safety requirement is not met.

B.29.2 Compliance Assessment for Pickering PSR2

B.29.2.1 Application of PSR1 Reviews

CSA N290.7 was not reviewed as part of PSR1 as the document did not exist at the time that the previous Darlington and Pickering B Integrated Safety Reviews and Pickering A Return to Service assessments were performed.

B.29.2.2 Application of Post PSR1 Reviews

As discussed above, N290.7 was not reviewed as part of PSR1. However, N-REP-69000-10003 R000, "Gap Analysis Between CSA N290.7-14 Cyber Security Requirements for Nuclear Power Plants and Small Reactor Facilities" [B.29-5], has been completed by OPG and satisfies the intent of this PSR2 High Level Review. The gap analysis and implementation plan for N290.7-14 was accepted by the CNSC, and the related Action Item 2015-OPG-7041 was closed [B.29-6]. For reasons of security and confidentiality, the findings of N-REP-69000-10003 R000 will not be discussed in PSR2.

B.29.3 Compliance Summary for Pickering PSR2

As discussed in Section B.29.2.2, for reasons of security and confidentiality, the findings of the gap analysis for N290.7-14 will not be discussed in PSR2.

B.29.4 References

B.30 NBCC (2010), "National Building Code of Canada"

B.30.1 Background

The following, paraphrased from the National Building Code of Canada (NBCC) 2010 [B.30-1] provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The National Building Code of Canada sets out technical provisions for the design and construction of new buildings. It also applies to the alteration, change of use and demolition of existing buildings. The NBCC details the minimum provisions acceptable to maintain the safety of buildings, with specific regard to public health, fire protection, accessibility and structural sufficiency.*

Appendix A of NBCC 2010 [B.30-1] states:

> *Application to Existing Buildings: This Code is most often applied to existing or relocated buildings when an owner wishes to rehabilitate a building, change its use, or build an addition, or when an enforcement authority decrees that a building or class of buildings be altered for reasons of public safety. It is not intended that the NBCC be used to enforce the retrospective application of new requirements to existing buildings or existing portions of relocated buildings, unless specifically required by local regulations or bylaws.*

The NBCC is relevant to Safety Factor 1 (Plant Design).

Compliance with NBCC is not a licence requirement for Pickering NGS (PROL 48.02/2018), although it is referred to in the R04 Pickering Licence Conditions Handbook [B.30-2] under Section 9.1 as a requirement for Structures, Systems and Components (SSCs) in the protected area for which OPG governance has specified that CSA N293-07 [B.30-3] is not applied. Also, it may be considered an indirect licence requirement as N293 is a licence requirement and refers to the NBCC as follows:

> *5.1.3 Where specific design or operational requirements are not addressed in this Standard, the NBCC, or the NFCC [National Fire Code of Canada], good engineering practice shall apply and, where appropriate, recognized Standards (such as those of the National Fire Protection Association [NFPA]) shall be used.*
>
> *5.5.2.2 Except as otherwise indicated in this Standard, plants shall be designed, modified, and constructed in accordance with all applicable requirements of the NBCC.*

The 2010 edition of the NBCC is the thirteenth edition of this standard. It includes revisions and errata released on December 21, 2012 and October 31, 2013. This edition incorporates a number of technical changes from the 2005 edition as outlined in Section B.30.2.2.

The results of PSR1 NBCC reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.30.2. As identified in Reference [B.30-4], the Pickering PSR2 review of the NBCC 2010 is an Incremental Review. PSR2

Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- Compliance: Compliance indicates that the change in the safety requirement, per the topical review, is met.
- Gap: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.30.2 Compliance Assessment for Pickering PSR2

B.30.2.1 Application of PSR1 Reviews

The versions of the NBCC (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

Pickering Units 5-8

OPG Report NK30-REP-03680-00001 R000, "Pickering NGS-B Integrated Safety Review - Plant Design Safety Factor" [B.30-5] performed a clause-by-clause evaluation of Safe Operating Envelope (SOE) systems and Systems Important to Safety (SIS) against Part 4, "Structural Design Requirements" of the 2005 version of the NBCC [B.30-6]. The sections of the NBCC Volume 2 listed below are not applicable to the safety functions of SOE or SIS systems and were therefore not reviewed:

- Part 1, "General";
- Part 2, "Reserved";
- Part 5, "Environmental Separation";
- Part 6, "Heating, Ventilating and Air Conditioning";
- Part 7, "Plumbing Services";
- Part 8, "Safety Measures at Construction and Demolition Sites"; and
- Part 9, "Housing and Small Buildings".

NBCC Part 3, "Fire Protection, Occupant Safety and Accessibility" was reviewed as part of OPG Report NK30-REP-71400-10001 R001, "Fire Protection Code Compliance Review Pickering Nuclear Generating Station B" [B.30-7] and will be discussed separately below.

The buildings within the scope of the review performed in NK30-REP-03680-00001 R000 were the Reactor Auxiliary Building, Turbine Hall, Turbine Auxiliary Bay, Emergency Water System, Emergency Power System Building, Powerhouse, Standby Generator Building and Unit Emergency Control Centres. The assessment did not include the Pickering B Concrete Containment Structures (CCSs) since they were assessed separately in the Pickering B ISR against the CSA N287 Series Standards (i.e., N287.1, N287.2 and N287.3, which exceed the requirements in the NBCC as stated in Section 1.1 of CSA N287.1 [B.30-8]). It is noted that CSA N287.1, N287.2, N287.3 and N287.5 have also been assessed separately as part of Pickering PSR2.

NK30-REP-03680-00001 R000 [B.30-5] found a number of gaps which were all classified as Acceptable Deviations as outlined below (text in italics taken verbatim):

- Sections 4.1.5.15, 4.1.5.16 and 4.1.5.17 - Loads on Guardrails: *The NBC*[18] *1970 specifies a live load of 2.2 kN/m whereas the NBC 2005 has addressed the requirement of 3.0 kN/m on grandstands. However, this does not impact the design of the SOE & SIS systems… The NBC 1970 specifies a concentrated load of 0.56 kN at any point of access ways to equipment platforms whereas the NBC 2005 has addressed the requirement of 1.0 kN on similar locations. However, this does not impact the design of the SOE & SIS systems.*

- Section 4.1.6 - Loads Due to Snow and Rain: *As per the evaluation conducted for NBC 2005 load due to rain or snow and associated rain, the conclusion are as follows: i. Loads due to rain need not be considered associated with snow. ii. The loads due to snow is higher than that of rain, therefore rain will not have major impact on design and is not considered. iii. The maximum permissible loads due to snow on the structures as per NBC 2005 are less than the snow load considered for the design of structures of Pickering B as per their Design Manuals.*

- Section 4.2.3.6 - Protection Against Chemical Attack: *As stated in Reference 9, Part 2, Section 2A2 (Technical Specification for Pickering B concrete) [Specification NK30-LH-20541-01, Part 2], the foundations were designed to meet A23.1-1973. Although the recent version of CSA A23.1 may introduce new requirements, the intent of this issue is considered to be met.*

- 4.3.2.1 Design Basis for Plain & Reinforced Masonry: *CSA S304.1 is the general standard for masonry design and was used in the Pickering B design. Although the recent version of CSA S304.1 may introduce new requirements, the intent of this issue is considered to be met.*

- 4.3.3.1 Design Basis for Plain, Reinforced & Pre-Stressed Concrete: *The requirements of the Article 4.3.3.1 are in compliance with Article 4.5.2.1 of NBC 1970. Although the*

[18] Note that NK30-REP-03680-00001 R000 (as well as other OPG documents cited in this review) use the acronym NBC instead of NBCC for the National Building Code of Canada.

recent version of CSA A23.3 may introduce new requirements, the intent of this issue is considered to be met.

- 4.3.4.1 Design Basis for Structural Steel: *Reference 5 (NBC 1970 Design Supplement), Section 1.3 specifies that structural is to conform to the requirements of S16-1965. Although the recent version of CSA S16 may introduce new requirements, the intent of this issue is considered to be met.*
- 4.3.4.2 Design Basis for Cold-Formed Steel: *The requirements of the Article 4.3.4.2 are in compliance with Article 4.6.2.2 of NBC 1970. Although the recent version of CSA S136 may introduce new requirements, the intent of this issue is considered to be met.*

All Acceptable Deviations (1-051 to 1-061) were documented and dispositioned in OPG Report, NK30-REP-03680-00015 R000, "Pickering NGS-B Integrated Safety Review (ISR) - Final ISR Report" [B.30-9]. The rationale for these findings being classified as Acceptable Deviations is not impacted by Pickering NGS operation past 2020.

NK30-REP-03680-00001 R000 [B.30-5] concluded:

> *The structures of the buildings have consistently met their performance requirements throughout 25 years of station operation and there are ongoing inspection and test programs to assess fitness for service similar to the Periodic Inspection Plan which exists for Vacuum Building, Pressure Relief Duct & Reactor Building for Concrete Components and other in-service inspection and leak testing of structures. These test programs… can be credited with the ability to detect and monitor any safety significant ageing mechanism and to provide assurance of continued fitness for the service of those structures.*

As discussed under the PSR2 reviews of CSA N287.1, N287.3 and N287.5, the CCSs at Pickering B were built and tested to meet 1970 NBCC requirements [B.30-10], supplemented by specific loading requirements and the requirements of Design Manuals (e.g., see [B.30-11], [B.30-12], [B.30-13], [B.30-14]) and Design Guides (e.g., see [B.30-15], [B.30-16], [B.30-17]). The original Pickering concrete specifications (L-715-80 [B.30-18] and NK30-LH-20541-01 [B.30-19]) included requirements for quality control and compliance with CSA A23.1, A23.2 and A23.3 (which address concrete materials, methods of concrete construction and test methods and standard practices for concrete). Ongoing confirmation that the Pickering NGS CCSs remain fit for service is demonstrated via periodic inspections and in-service testing (i.e., CSA N287.7, "In Service Examination and Testing Requirements for Concrete Containment Structures for CANDU Nuclear Power Plants" and N285.5, "Periodic inspection of CANDU Nuclear Power Plant Containment Components"). This testing, together with the aging management program, are credited with the ability to detect and monitor any safety significant degradation mechanisms and thus to provide assurance of continued fitness for service of the Pickering NGS CCSs.

As discussed earlier, Part 3 of the NBCC 2010, "Fire Protection, Occupant Safety and Accessibility" was reviewed as part of OPG Report NK30-REP-71400-10001 R001 [B.30-7]. As part of the Code Compliance Review (CCR), changes between the 1995 and 2005 editions of the NBCC were identified. The CCR concluded that the changes between the current and previous editions of the NBCC and other standards referenced therein have no safety impact on the existing physical features of the station, as they are not intended to be applied retroactively. As such, they would be applicable only to new construction including modifications undertaken at the station subsequent to adoption of the new codes and standards under the site operating license. Section 2.1 of [B.30-7] states:

> *The 1970 edition of the NBCC and the 1963 edition of the NFCC were in effect at the time that PNGS B was issued a construction permit (dated July 19, 1974). Therefore, fire safety requirements were enforced by application of the 1970 NBCC and the 1963 NFCC to PNGS B as the Codes of Record and are documented as such in the station operating license.*
>
> *The 1970 edition of the NBCC and the 1963 NFCC were used for the 2010 CCR as those portions of the 2005 NFCC that relate to the design and installation of structures, systems, and components are not retroactive. This concept was applied to any fixed system or component such as fire barriers, tanks, and piping systems for the transfer of combustible liquids. For these features, the requirements of the 1963 Edition of the NFCC were considered applicable…*
>
> *Systems and/or structures installed or constructed since May 2000 are required to be installed in accordance with the applicable NBCC and NFCC that were in force as referenced in the Power Reactor Operating License (PROL) for PNGS B at the time of design. Those installed or constructed between May 2000 and June 2008 are required to conform to the 1995 edition of the Codes. Those installed subsequent to June 2008 are required to conform to the 2005 edition.*

The updated 2010 CCR identified a number of new Deviations against the 1970 and 1975 editions of the NBCC which were minor in nature, as identified in Appendix C of NK30-REP-71400-10001 R001 [B.30-7]. These Deviations were subsequently addressed, per OPG Letter NA44-CORR-00531-06935 R000, "Pickering NGS 'A' - Request for CNSC Acceptance of the "Fire Safe Shutdown Analysis" (FSSA) and "Fire Hazard Assessment" (FHA) Reports and Status Update on CCR/ITM Deviations" [B.30-20]. The closure criteria for these findings is not impacted by Pickering NGS operation past 2020.

It is noted that CSA N293 addresses specific nuclear fire protection design, operational and performance requirements, and a review against the latest version of N293-12 (including of design-related aspects) is addressed as part of PSR2. In addition, Nuclear Oversight conducts an annual audit to assess Fire Protection provisions in accordance with CSA N293 Appendix E, "Fire Inspections and Audits" to provide assurance that the inspection requirements of the NFCC, including Inspection, Testing, and Maintenance (ITM) activities, are being met pursuant to the Nuclear Power Reactor Operating License [B.30-21].

Based on the above, there are no PSR2 gaps associated with the Pickering B ISR review (or subsequent CCR) which addressed compliance against the 2005 version of the NBCC. Compliance against the 2010 version of the NBCC is addressed under Section B.30.2.2 below.

Pickering Units 1,4

OPG Letter, NA44-CORR-00531-00381 R000, "Pickering A - Updated Basis for Return to Service Document" [B.30-22] included a CCR against the 1995 version of the NBCC, taking into account differences from the 1965 NBCC requirements [B.30-23] to which the CCSs at Pickering A were built and tested to meet. No significant deficiencies were identified. OPG undertook Regulatory Commitments to address the identified deviations prior to the return to service of Units 1 and 4, and these commitments were reflected in Section VI, Page VI-58 of [B.30-22]. The past dispositions of these deviations are not impacted by Pickering NGS operation beyond 2020.

OPG Report NA44-REP-71400-10001 R001, "Pickering Nuclear Generating Stations "A" Fire Protection Code Compliance Review" [B.30-24] provided an update to the original March 2000 CCR [B.30-25]. Changes between the 1995 and 2005 editions of the NBCC were identified. With respect to design-related aspects of the NBCC, the Pickering A CCR made similar arguments as in the Pickering B review with respect to retroactive application, i.e., that it is generally not practicable to make structural changes to existing buildings without rebuilding them. The updated 2010 CCR identified a number of new Deviations against the 1965 and 1970 editions of the NBCC which were minor in nature, per Appendix C of NA44-REP-71400-10001 R001 [B.30-24]. The findings were subsequently addressed to the satisfaction of the CNSC, per OPG Letter NA44-CORR-00531-06837 R000, "Pickering NGS A – CNSC Acceptance of Fire Protection Code Compliance Review and Third Party Review, Fixed Fire Protection Systems Inspection Testing and Maintenance" [B.30-26]. The closure criteria for these findings is not impacted by Pickering NGS operation past 2020.

Based on the above, there are no PSR2 gaps associated with the Pickering A Return to Service review (or the subsequent CCR) which addressed compliance against the 2005 version of the NBCC. As discussed earlier, compliance against the 2010 version of the NBCC is addressed under Section B.30.2.2 below.

Darlington NGS

OPG Report NK38-REP-03680-10048 R001, "Review of National Building Code of Canada (2005), National Building Code of Canada for Darlington Integrated Safety Review" [B.30-27] identified gaps at Darlington NGS related to requirements for the seismic design of buildings, guardrails and firewall design for lateral loads. OPG Report NK38-REP-03680-10104 R000, "Darlington NGS Integrated Safety Review (ISR) - Final ISR Report" [B.30-28] combined the gaps into Issues D077/D078, placed the fire protection related gaps under N293 Issues D044/D222, and classified all as Acceptable Deviations with very low safety significance and no further action required.

OPG Report NK38-REP-03680-10125 R002, "Gap Analysis to National Building Code of Canada 2005, Part 3, for Darlington Integrated Safety Review" [B.30-29] reviewed Part 3, "Fire Protection, Occupant Safety and Accessibility" of the NBCC as it had not been included in the NK38-REP-03680-10048 R001 review. This review found a number of gaps, but concluded:

> *Based on the small number of gaps identified relative to the number of clauses, and the generally minor nature of such gaps, the design and construction of the buildings*

within the scope of this review is deemed to be substantially in accordance with the requirements of the NBCC 2005.

Given the reviews completed for Pickering Units 1,4 and 5-8 against the 2005 version of the NBCC, the above reviews are not assessed further for applicability to PSR2. However, it is noted that OPG Reports NK38-REP-03680-10173 R000, "Code Refresh Review of National Building Code of Canada (2010)" [B.30-30] and NK38-REP-03680-10190 R001, "Code Review Refresh of the National Building Code of Canada: 2010 Edition" [B.30-31] compared the 2010 NBCC to the 2005 NBCC to identify if there were additional gaps beyond those identified in OPG Report NK38-REP-03680-10048 R001 [B.30-27]. NK38-REP-03680-10173 R000 [B.30-30] confirmed that changes in the 2010 NBCC do not affect the existing ISR, and the contents of that review, together with the reviews of NK38-REP-03680-10190 R001 [B.30-31], NK38-REP-03680-10048 R001 [B.30-27] and NK38-REP-03680-10125 R002 [B.30-29], have been utilized in Section B.30.2.2 below to assess Pickering NGS compliance against the 2005 and 2010 versions of the NBCC.

B.30.2.2 Application of Post PSR1 Reviews

Per the National Research Council of Canada, the major changes in the NBCC from 1995 to 2005 are summarized as follows [B.30-32]:

- Changes to Part 5 (Environmental Separation) and Part 6 (Heating, Ventilating and Air Conditioning (HVAC)), including new requirements for controlling air leakage and vapour diffusion, and revised wording to clarify the types of spaces in buildings that do not require mechanical ventilation (such as closets, storage rooms or other such spaces). These changes are not safety significant for PSR2.

- Changes to Part 9 (Housing and Small Buildings) which are not applicable to Pickering NGS.

- Changes to Part 3 (Fire Protection, Occupant Safety and Accessibility):

  - Materials of limited combustibility that pose a low fire risk are now allowed based on specific new test criteria. This is a relaxation of requirements and is therefore not safety significant for PSR2.

  - There has been a change from a prescriptive requirement to a more performance-based requirement to allow for materials other than masonry or concrete for the construction of firewalls requiring a rating of up to two hours (which would allow firewalls to be constructed of gypsum board provided certain conditions are met). This change in prescriptiveness is not safety significant for PSR2.

  - A number of changes have been made regarding mezzanines including: allowing the enclosure of the space below open mezzanines, redefining the point of reference to calculate the area of open mezzanines, imposing an area limit of 10% of the suite in which the mezzanine is located, allowing an enclosed space on open mezzanines, and clarifying the provisions for means of egress from mezzanines. This was assessed to be an Acceptable Deviation for Darlington in NK38-REP-03680-10125 R002 [B.30-29], since the implications of having to upgrade the building to meet the current code requirements (due to the code change in the determination of building height) are substantial and it is cost prohibitive to do so. Furthermore, Article 3.2.2.2 of NBCC 2005, which applies to the Powerhouse, provides for special considerations for structures of unusual proportion, special occupancy hazards and use. These considerations and conclusions also apply to Pickering NGS.

  - Larger non-metallic conduits within a fire compartment (without penetrating a fire separation) are permitted. This is a relaxation of requirements and is therefore not safety significant for PSR2.

- Changes to Part 4 (Structural Design), including:

  - Separation of snow and rain loads from "live load". Darlington was assessed to meet the intent of these changes in NK38-REP-03680-10048 R001 [B.30-27], given the use of conservative load factors and additional load combinations being considered in the design of various plant safety-related structures. These considerations also apply to Pickering NGS.

  - Earthquake data is more often described in the form of spectral acceleration values (related to motion in the ground) and is more geographically specific than the previous zonal values. Dynamic analysis was also established as the default method for analyzing earthquake design. Darlington was assessed to meet the intent of these changes in NK38-REP-03680-10048 R001 [B.30-27], since the seismic design of structures which contain safety-related systems is based primarily on the CSA N289 series of standards and not the NBCC. Since NBCC seismic requirements are only used on parts of the nuclear power plant that do not impact nuclear safety, it follows that changes to the NBCC requirements do not have an impact on nuclear safety. These considerations and conclusions also apply to Pickering NGS. It is noted that the CSA N289 series of standards are assessed separately as part of PSR2.

  - To establish a harmonized approach for calculating the environmental design loads for different categories of buildings, a table of "Importance Categories" (i.e., "low," "normal," "high" and "post-disaster" categories delineating hazard in the event of failure or required functionality in the event of a disaster) was created based on their use and occupancy. Darlington was assessed to meet the intent of these changes in NK38-REP-03680-10048 R001 [B.30-27], since the intent of the clauses was deemed to be unchanged from previous versions of the NBCC. Given that the intent has not changed, this is not safety significant for PSR2.

Per the National Research Council of Canada, the major changes in the NBCC from 2005 to 2010 are summarized as follows [B.30-33]:

- Changes to the organization of the Code (including clarifications). These do not affect the requirements.

- Changes to requirements for housing and small buildings, theatres and arenas/stadia (NBCC Part 9). These are not applicable to Pickering NGS.

- Crane and vehicle loads are more explicitly defined (NBCC Part 4). These changes are not safety significant for PSR2.

- Changes to the requirements for non-structural features such as window openings, stairs, handrails, radon levels and HVAC/ventilation (including particulate, ozone and carbon monoxide levels) (NBCC Parts 5 and 9). These changes are not safety significant for PSR2.

- A new occupancy classification for residential care facilities has been created (Group B3 occupancy) that relaxes requirements for smaller care occupancies having a limited number of occupants (NBCC Part 3, NFCC Part 2). These items are shared with the National Fire Code of Canada, and are not applicable to Pickering NGS.

- Revisions were made to seismic requirements related to site properties, irregularities, steel structures, static and dynamic procedures, and diaphragms. As outlined in [B.30-30], NBCC 2005 has similar requirements and the intent of these revisions has not changed (NBCC Part 4). Therefore, the conclusions of past Pickering NBCC 2005 code reviews remain valid.

- There are new wind load requirements for buildings with very long periods of vibration stating that they must now be designed by experimental methods and not dynamic calculations (NBCC Part 4). As outlined in [B.30-30], NBCC 2005 has similar requirements and the intent of these additions has not changed. Therefore, the conclusions of past Pickering NBCC 2005 code reviews remain valid.

- Seismic effects are now taken into account only for post-disaster buildings (i.e., buildings essential to the continued provision of services in the event of a disaster) (NBCC Part 5). As outlined in [B.30-30], NBCC 2005 has similar requirements and the intent of these additions has not changed. Therefore, the conclusions of past Pickering NBCC 2005 code reviews remain valid.

- To draw a clear line between the roles of the NBCC and the NFCC, building design requirements presently in the NFCC were moved to the NBCC (except for spill control measures). Appropriate cross-referencing between the two codes was added. This does not affect the requirements.

- New construction, sprinkler, emergency power and fire alarm requirements were added that are shared with the NFCC (NBCC Part 3, NFCC Part 2). In addition, Part 3 "Fire Protection, Occupant Safety and Accessibility" was updated to reflect the following changes:

- Additional fire protection requirements were introduced relating to the construction of all buildings in proximity to one another or to the property line;
- New requirements and clarifications were introduced for smoke alarm placement, commissioning of life safety and fire safety systems, and when fire alarm components must be installed;
- Definitions for "fire stops" and "fire blocks" have been added, as were several changes addressing penetrations through fire separations;
- Requirements addressing green pictograms conforming to ISO standards and photoluminescent exit signs were introduced;
- New protection requirements are provided for electrical conductors located in high buildings, fire pumps, refuge areas, and contained use areas; and
- New requirements were introduced for electrical supervision of water supply system valves.

The above changes were addressed in OPG Report NK38-REP-03680-10190 R001 [B.30-31], and gaps were identified that were subsequently grouped into ISR Issues D519 and D524 to D530. These were all later classified as Acceptable Deviations with no safety impact in References [B.30-34] to [B.30-41]. The rationale for these gaps being classified as Acceptable Deviations at Darlington NGS is also generally applicable to Pickering NGS, and include the following arguments:

- Fire Hazard Analysis (FHA) and the Fire Safety Shutdown Analysis (FSSA) demonstrate that the safety objectives of the Station can be met under postulated fire scenarios. An FHA and FSSA have also been completed for Pickering Units 1,4 and Units 5-8.
- In the event of a fire at the Station, personnel, as per training and as instructed via the public address system, are to avoid the incident unit and area as well as to refrain from using the elevators. This also applies to Pickering NGS.
- Access to the Station is limited to trained personnel who are familiar with the hazards and safety features of site buildings. Multiple means of egress are available and existing signage is clearly recognizable and understood by the personnel accessing the Station buildings. This also applies to Pickering NGS.
- Although there is a lack of smoke detection near the entrance to certain areas of the Station, it unlikely that these fires would go undetected and unreported given the plant is served by multiple alternate means of egress. There are also multiple alternate means of egress at Pickering NGS.
- With respect to electrical conductors, there are no high-rise buildings, areas of refuge, or contained use areas located at Darlington NGS. This also applies to Pickering NGS. The Darlington ISR originally identified that there was no evidence that the electrical cables serving Darlington fire pumps are protected in

according with this requirement; however, Pickering NGS does not have electrically driven fire pumps so this finding is not applicable.

- Although the absence of electronic supervision for fire protection water supply valves could result in a valve being closed without sending an alert to central alarm monitoring, water supply valves without electronic supervision are locked in an 'open' position at Darlington which would prevent unintended closure. As per Section 11.3 of Appendix B of [B.30-42] for Pickering Units 1,4 and Section 4.2 of [B.30-43] for Pickering Units 5-8, this is the expectation for Pickering NGS as well. Nevertheless, as discussed under the PSR2 review for NFPA 24, a number of yard post indicator valves at Pickering NGS without electronic supervision do not have locking mechanisms. Resolution of this finding is currently in progress with locks now installed on the majority of the affected valves. This was identified as a PSR2 gap under the NFPA 24 review (PSR2 NFPA 24 Gap #1) and is not duplicated as part of this NBCC review.

Based on the above, there are no Pickering NGS safety significant findings (PSR2 gaps) against the 2005 or 2010 versions of the NBCC. The changes to the 2005 and 2010 versions of the NBCC are largely incremental in nature due to minor improvements in knowledge and the addition of clarifications, and do not impact the overall adequacy of the previous Pickering Units 1,4 and Units 5-8 reviews against the NBCC (which are not impacted by Pickering NGS operation past 2020).

B.30.3 Compliance Summary for Pickering PSR2

There are no PSR2 gaps for NBCC (2010) [B.30-1]. Per the definition of Compliance for an Incremental Review, Pickering has a PSR2 Compliance associated with NBCC (2010).

B.31 NFCC (2010), "National Fire Code of Canada"

B.31.1 Background

The following, paraphrased from the 2010 National Fire Code of Canada (NFCC) [B.31-1], provides a brief overview of the purpose of this standard and the requirements expressed therein:

> *The National Fire Code of Canada purpose is to limit the probability that, as a result of specific circumstances related to the building or facility, a person in or adjacent to the building or facility will be exposed to an unacceptable risk of injury.*

As identified in Appendix A of [B.31-1]:

> *A.2.1.3.1.(.1) The National Building Code of Canada [NBCC] is most often applied to existing buildings when an owner wishes to rehabilitate a building, change its use, or build an addition; or when an enforcement authority decrees that a building, or a class of buildings, be altered for reasons of public safety. It is not intended that either the NBC [National Building Code] or the NFC be used to enforce the retrospective application of new requirements in the NBC to existing buildings…*
>
> *It is usually difficult to change structural features of an existing building when undertaking alterations or additions, but the installation of "active" fire protection systems, such as alarms, sprinklers and standpipes, in existing buildings may be possible. These systems may be considered as contributing to an adequate degree of life safety in cases where the structural features of a building do not conform to the NBC.*
>
> [Clause A.2.1.3.1.(.1)] *is intended to address the installation of fire alarm, sprinkler and standpipe systems in existing buildings presently not so equipped, and in existing buildings that do not provide an acceptable level of safety to meet the current installation standards specified in the NBC. It is not intended that existing fire protection systems that provide an acceptable level of life safety be upgraded with each new edition of the NBC or in conjunction with the inclusion of new requirements not in force at the time that a building was constructed.*

The NFCC is relevant to Safety Factor 1 (Plant Design).

Compliance with the NFCC is not a licence requirement for Pickering NGS (PROL 48.02/2018), although it is referred to in Section 9.1 of the R04 Pickering Licence Conditions Handbook [B.31-2] which states that OPG governance has identified specific Structures, Systems and Components (SSCs) in the protected area for which the requirements of CSA N293 [B.31-3] are not applied, and the requirements of the NFCC apply in those cases. Also, it may be considered an indirect licence requirement as N293 is a licence requirement and refers to the NFCC as follows:

> *5.1.3 Where specific design or operational requirements are not addressed in this Standard, the NBCC, or the NFCC, good engineering practice shall apply and, where*

appropriate, recognized Standards (such as those of the National Fire Protection Association [NFPA]) shall be used.

5.5.2.3 Except as otherwise indicated in this Standard, plants shall comply with all applicable requirements of the NFCC.

The 2010 edition of the NFCC is the ninth edition of this standard, and includes errata released in December 2012 and revision released in November 2013. This edition incorporates a number of technical changes from the 2005 edition as outlined in Section B.31.2.2.

The results of PSR1 NFCC reviews (Pickering A Return to Service assessments, and Pickering B and Darlington Integrated Safety Reviews (ISRs)), as well as reviews performed since PSR1, have been assessed for applicability to PSR2 in Section B.31.2. As identified in Reference [B.31-4], the Pickering PSR2 review of the NFCC (2010) is an Incremental Review. PSR2 Incremental Review includes an assessment of the intent of recent changes to the Law, Regulation, Code or Standard on a topic or subject-matter basis where there is potential to impact nuclear safety. The review identifies Compliances and Gaps, where required, as defined below:

- <u>Compliance:</u> Compliance indicates that the change in the safety requirement, per the topical review, is met.
- <u>Gap</u>: A Gap indicates that the change in the safety requirement, per the topical review, is not met.

B.31.2 Compliance Assessment for Pickering PSR2

B.31.2.1 Application of PSR1 Reviews

The versions of the NFCC (or its predecessors) subject to previous PSR1 reviews conducted for Pickering and Darlington, as well as their applicability to Pickering PSR2, are identified and discussed below.

Pickering NGS

<u>Pickering Units 5-8</u>

OPG Report NK30-REP-03680-00001 R000, "Pickering NGS-B Integrated Safety Review - Plant Design Safety Factor" [B.31-5] performed a clause-by-clause evaluation of Safe Operating Envelope (SOE) systems and Systems Important to Safety (SIS) against the 2005 version of the NFCC. The review found Pickering B to be in compliance, with 2 Acceptable Deviations (1-063/1-079) and 1 Discrepancy (1-469).

With respect to Discrepancy 1-469, NK30-REP-03680-00001 R000 stated:

According to Pickering B Design Manual, EPS [Emergency Power Supply] Generators Fuel Oil System, NK30-54860, Rev. 2, Jun 1982 and the Pickering B Design Manual, Standby Generators Fuel Oil System, NK30-54660, Rev. 2, Jul 1982, the Standby Generator and Emergency Power Generator tanks are allowed to be separated by 1/6 of the sum of the *two tank diameters. This is inconsistent with Section 4.3.2.2 (1) of the National Fire Code (NFC).*[19] *This is a documentation discrepancy only; the actual configurations of the storage tanks meet NFC requirements.*

Action Request # 28134694 (Assignment -06, relating to revision to Fuel Oil System Design Manuals to resolve the documentation discrepancies) was subsequently completed and Discrepancy 1-469 closed, per NK30-PLAN-00531-00001 R005, "Pickering 5-8 Continued Operations Plan" [B.31-6]. This resolution is not impacted by Pickering NGS operation past 2020.

Issue 1-079 was related to Clause 4.5.6.7 of NFCC 2005 regarding piping for flammable or combustible liquids at the entrance to buildings being above grade, and which was later reclassified from an Acceptable Deviation to a Discrepancy in OPG Letter NK30-CORR-00531-04739 R000, "Pickering NGS-B Integrated Safety Review - Discrepancy Resolution" [B.31-7]. OPG Report NK30-REP-03680-00016 R000, "OPG Response to CNSC Comments on Pickering NGS-B Integrated Safety Review - Plant Design, Safety Analysis, Safety Performance, Ageing and Equipment Qualification Safety Factors and Discrepancy Resolutions" [B.31-8] acknowledged CNSC agreement with OPG's disposition for Issue 1-079. In CNSC Letter NK30-CORR-00531-06324 R000 [B.31-9], CNSC staff requested additional information regarding Issue 1-079, and indicated it would be tracked via new Action Item I03-1. NK30-PLAN-00531-00001 R005 [B.31-6] addressed this and stated:

OPG has determined that the Pickering B Standby Generator and EPG [Emergency Power Generator] Fuel Oil storage tank systems comply with the NFCC. A review provided in Enclosure 5 NK30-REP-54600-00053, "Preliminary Tank Assessment Report Review of Pickering B Standby Generator and Emergency Power Generator Fuel Oil System" confirms OPG's interpretation of NFC Part IV Section 4.1.1.1 and subsequent implementation of CSA B139-00 and concludes that the Standby Generator and EPG Fuel Oil storage tank systems as designed meet the requirements of CSA B139-00. Furthermore, no changes to fuel oil piping requirements were identified from a review of CSA B139-00 to CSA B139-04. Hence OPG is in compliance with CSA B139-04 regarding piping at building entrances. Gap 1-079 is closed and this action is complete.

Based on the above, there is no Pickering Units 5-8 gap associated with Issue 1-079 (Action Item I03-1). However, a similar PSR2 gap for Pickering Units 1,4 has been identified in OPG Report P-REP-03680-00024 R000, "Pickering 5-8 Continued Operations Plan Review in Support of PNGS Periodic Safety Review 2" [B.31-10]. ID # 44, IIP Code I03-1, from Section 4.0 of P-REP-03680-00024 R000 states:

An assessment that shows that Standby Generator fuel tanks supporting Units 1,4 comply with NFCC could not be found.

The rationale for classification of Issue 1-063 as an Acceptable Deviation (which was related to NBCC 2005 Clauses 2.1.6.10 and 4.3.7.2 regarding the installation of impermeable dyke liners

---

[19] Note that NK30-REP-03680-00001 R000 (as well as other OPG documents cited in this review) use the acronym NFC instead of NFCC for the National Fire Code of Canada.

for Standby Generator and the Emergency Power Generator tanks) is not impacted by operation past 2020.

OPG Report NK30-REP-03680-00001 R000 [B.31-5] did not assess the Pickering B Fire Protection System as part of the review, as it was not classified as an SOE or SIS system. However, a Code Compliance Review (CCR) was prepared in 2000 in OPG Report, NK30-REP-71400-10001 R000, "Fire Protection Code Compliance Review Pickering Nuclear Generating Station B" [B.31-11] to document compliance of Pickering B with the requirements of the NBCC, NFCC and applicable NFPA standards. Since completion of the original 2000 CCR, a new edition of CSA N293 was added to the Pickering PROL [B.31-2]. The updated standard (N293-07) requires that the original CCR be updated to reflect current station conditions. This was completed in OPG Report NK30-REP-71400-10001 R001, "Fire Protection Code Compliance Review Pickering Nuclear Generating Station B" [B.31-12]. A gap analysis was performed and documented prior to initiating the 2010 CCR update [B.31-13]. As part of the gap analysis, changes between the 1995 and 2007 editions of CSA N293 deemed to impact the CCR were identified as well as those between the 2005 and 1995 editions of the NBCC/NFCC.

Three main evaluations were performed for the 2010 CCR [B.31-12]:

- Update the status of code deviations identified in the original 2000 CCR [B.31-11];
- Evaluate new system/construction; and
- Evaluate buildings not covered by the original CCR (including Filtered Air Discharge (FAD) Tower[20], FAD Building, and Emergency Coolant Injection Shield Tower).

The 2010 CCR NK30-REP-71400-10001 R001 [B.31-12] states:

> *The approach used in the original CCR was to first analyze the structure in relation to the specific design requirements of the NBCC and NFCC. During the initial plant review and evaluation, experienced fire protection personnel identified areas of potential deviation from code criteria. The identification of deviations was based on the following considerations: a) The field inspection teams visually inspected existing fire protection features, including walls and doors used to enclose exit stairs, b) The field inspection teams reviewed existing fire protection feature documentation, inclusive of inspection and testing procedures, for identification of operational deficiencies, and c) Design deficiencies were identified by a review of design documentation, supplemented by walk downs as appropriate. Each deficiency was subjected to an engineering evaluation… The purpose of the engineering evaluation was to identify if the current plant construction and/or administrative control met the safety intent of the code through an alternate means… Where an alternate method of compliance for a potential design deficiency could not be substantiated, recommendations for corrections were provided. The recommendations, which consist of changes to physical plant or administrative*

[20] The FAD Tower houses the FAD system suction line.

controls, appropriately consider compliance to current versions of the code. The 2010 CCR followed the same general analysis approach used in the original CCR.

All past deviations from the 2000 CCR were resolved per Appendix E of NK30-REP-71400-10001 R001 [B.31-12]. The following new deviations against NFCC 2005 were identified in Appendix C of [B.31-12] (text taken verbatim is in italics):

- Clause 6.1.1.2 (Deviations No. 2010-0800 and 2010-0801): *Two fire hose cabinets were identified as being out of service. These fire hose cabinets included: Service Wing Extension, elevation 324 - #71410-FHC44, and RAB, elevation 317 - #71410-FHC83. Maintenance should be performed and the fire hose cabinets placed back in service in order to maintain the intended level of fire and life safety in the station. In addition, two fire hose cabinets were identified as out of service in the Service Wing Extension which include: FHC44, elevation 324 ft, Unit 018, and FHC 37, elevation 274, Unit 018. Signage provided on this FHC identified an out of service date of Feb 17, however, a year was not identified. Fire protection installations shall be maintained in operating condition (2005 NFCC, 6.1.1.2.). The fire hose cabinets should be repaired and placed back in service.*

These Deviations were subsequently addressed, as identified in OPG Letter NA44-CORR-00531-06935 R000, "Pickering NGS 'A' - Request for CNSC Acceptance of the "Fire Safe Shutdown Analysis" (FSSA) and "Fire Hazard Assessment" (FHA) Reports and Status Update on CCR/ITM Deviations" [B.31-14].

NK30-REP-71400-10001 R001 [B.31-12] states:

> *With respect to the NFCC, the gap analysis concluded that that the changes between the current and previous* [1995 and 2005] *edition of Code that impact the CCR are limited to inspection, testing and maintenance requirements for fire protection systems serving the station… The original CCR included a detailed analysis of the inspection, testing and maintenance requirements of fire protection equipment and features. This updated CCR excludes such discussion. The inspection, testing and maintenance requirements are addressed in separate evaluation reports addressing compliance of the fire protection program at the station; specifically the inspection, testing and maintenance of automatic and manual fire protection systems.*

The Inspection, Testing, and Maintenance (ITM) requirements that applied to the fire alarm life safety systems at Pickering B were addressed under OPG Report NK30-REP-71400-00027 R000, "Third Party Review: Fixed Fire Protection Systems Inspection, Testing and Maintenance Report" [B.31-15]. The objective of the Third Party Review was to assess OPG's evaluation of the ITM program as it applies to fixed fire protection systems at Pickering B for compliance with the requirements of applicable codes and standards and other relevant documents referenced therein, which included the 2005 edition of the NFCC. The review of OPG's compliance evaluation resulted in the identification of nine deviations specifically related to NFCC 2005 as discussed below (text taken verbatim is in italics). In each case, the Third Party vendor concurred with OPG's disposition.

- Clause 6.5.1.6 (1) (Deviation No. 64): *Description - A visual inspection of self-contained emergency lighting units must be conducted monthly. OPG Disposition - PMIDs will be created for direct compliance.*

- 6.5.1.7 (Deviation No. 66): *Description - Emergency lights must be inspected annually to ensure that they are functional. OPG Disposition - Emergency lights operating on Class II power do not require annual inspection to confirm functionality. These lights are in continuous operation, demonstrating their functionality. During a power outage Class II power switches to a battery supply, this supply is tested as per E1, E2, E5, and ES. Any light that fails during normal operation is repaired in accordance with N-PROC-MA-0008. Light failures would be detected by personnel conducting normal daily activities, or during shifty operator rounds, P-INS-09100-00004.*

- 6.5.1 (2)(a) (Deviation No. 67): *Description - Self-contained emergency lighting units must be tested monthly for operation upon failure of primary power supply.* (The Vendor reviewed Emergency Response Maintainer Procedure P-ERP-71400-00010, "Monthly Exit Inspections", and agreed this document addresses the issue.)

- 6.5.1.6 (2)(b) (Deviation No. 69): *Description - Test self-contained emergency lighting units to ensure that unit provides emergency lighting for duration equal to the design criterion under simulated power failure conditions. OPG Disposition - OPG will update PMIDs to test the emergency lights for the design period.*

- 6.5.1.6 (3) (Deviation No. 70): *Description - The charging conditions for voltage, current, and the recovery prior of self-contained emergency lighting units must be tested annually. OPG Disposition - PMIDs to be created for direct compliance.*

- 2.7.2.1 (1) (Deviation No. 76): *Description - All doors forming part of a means of egress shall be tested at intervals not greater than one month to ensure that they are operable. OPG Disposition - Meet the intent of this requirement as fire doors are checked monthly, exterior doors are checked by security daily and there are no public corridors where the passage of smoke would be a concern. Also, the buildings are large with high ceilings and staff are advised via PA [Public Address] if an incident occurs. The buildings are not open to the public, and OPG staff are required to initiate repairs to the plant, including doors, as per N-PROC-MA-0008 (work initiation, approval and prioritization).*

- 2.7.2.1 (2) (Deviation No. 77): *Description - The safety features of revolving doors shall be tested at intervals not greater than 12 months. OPG Disposition - Not applicable since PNGS B does not utilize revolving doors.*

- 2.7.2.1 (3) (Deviation No. 78): *Description - Sliding doors that are required to swing on their vertical axis in the direction of egress when pressure is applied shall be tested at intervals not greater than 12 months. OPG Disposition - Not applicable since PNGS B does not utilize sliding doors.*

- 2.7.2.1 (4) (Deviation No. 79): *Description - When doors are equipped with electrometric locks, these locks shall be tested at intervals not greater than 12 months. OPG Disposition - Not applicable since PNGS B does not utilize electromagnetic doors.*

OPG Report NK30-REP-71400-00027 R000 [B.31-15] states that "a satisfactory disposition has been reached to resolve all noted deviations."

Based on the above, there are no PSR2 gaps associated with the Pickering B ISR review (or subsequent CCR) which addressed compliance against the 2005 version of the NFCC. Compliance against the 2010 version of the NFCC is addressed under Section B.31.2.2 below.

Pickering Units 1,4

OPG Letter, NA44-CORR-00531-00381 R000, "Pickering A - Updated Basis for Return to Service Document" [B.31-16] included a CCR against the 1995 version of the NFCC, taking into account differences from the 1963 NFCC requirements [B.31-17] which Pickering A was built and tested to meet. No significant deficiencies were identified. OPG undertook Regulatory Commitments to address the identified deviations prior to the return to service of Units 1 and 4, and these commitments were reflected in Section VI, Page VI-58 of [B.31-16]. The past dispositions are not impacted by Pickering NGS operation past 2020.

As was done for Pickering B, a CCR was prepared in 2000 in OPG Report NA44-REP-71400-10001 R000, "Pickering Nuclear Generating Station "A" Fire Protection Code Compliance Review" [B.31-18] to document compliance of Pickering A with the requirements of the NBCC, NFCC and applicable NFPA standards. The original 2000 CCR was updated in 2010 to reflect current station conditions, as outlined in OPG Report NA44-REP-71400-10001 R001, "Pickering NGS A Fire Protection Code Compliance Review (CCR)" [B.31-19]. A gap analysis was also performed and documented prior to initiating the 2010 CCR update [B.31-20]. As part of the gap analysis, changes between the 2005 and 1995 editions of the NFCC were assessed. The 2010 CCR found nine deviations from the NFCC (including one remaining deviation from the 2000 CCR). All deviations were minor in nature with no impact on safety (e.g., missing labelling, burnt out light bulbs). The findings were addressed to the satisfaction of the CNSC per OPG Letter NA44-CORR-00531-06837 R000 [B.31-21]. The rationale for these findings being classified as non-safety significant is not impacted by Pickering NGS operation past 2020.

In addition to the above work, the ITM requirements that applied to the fire alarm life safety systems at Pickering Units 1,4 were addressed under OPG Report NA44-REP-71400-00022 R000, "Third Party Review: Fixed Fire Protection Systems Inspection, Testing and Maintenance Report" [B.31-22]. The objective of the Third Party Review was to assess OPG's evaluation of the ITM program as it applies to fixed fire protection systems at Pickering A for compliance with the requirements of applicable codes and standards and other relevant documents referenced, which included the 2005 edition of the NFCC. The review of OPG's compliance evaluation resulted in the identification of 10 deviations applicable to the 2005 NFCC. Similar to Pickering B, these deviations were not safety significant and have subsequently been addressed to the satisfaction of the CNSC, as identified in [B.31-14] and [B.31-21].

Based on the above, there are no PSR2 gaps associated with the Pickering A Return to Service review (or subsequent CCRs) which addressed compliance against the 1995 and 2005 versions of the NFCC. As discussed earlier, compliance against the 2010 version of the NFCC is addressed under Section B.31.2.2 below.

Darlington NGS

OPG Reports NK38-REP-03680-10049 R000, "Review of National Fire Code of Canada (2005) for Darlington Integrated Safety Review" [B.31-23] and NK38-REP-03680-10130 R002, "Gap Analysis of the National Fire Code of Canada 2005 Edition for the Darlington Integrated Safety Review" [B.31-24] found gaps against a number of clauses of NFCC 2005, largely because solid supporting evidence of compliance could not be retrieved. NK38-REP-03680-10130 R002 concluded:

> *Based on the small number of gaps identified relative to the number of clauses, and the generally minor nature of many of the gaps, the Station is deemed to be substantially in accordance with the requirements of the NFCC.*

Given the CCR reviews completed for Pickering Units 1,4 and 5-8 against the 2005 version of the NFCC, the above Darlington ISR reviews were not assessed further for applicability to PSR2. However, it is noted that OPG Report NK38-REP-03680-10188 R001, "Code Review Refresh of the National Fire Code of Canada, 2010 Edition" [B.31-25] reviewed the 2005 edition of the NFCC against the 2010 edition. Twelve gaps were identified and all were classified as having low safety significance. The content of NK38-REP-03680-10188 R001 has been utilized in Section B.31.2.2 below to assist in assessing Pickering NGS compliance against the 2010 version of the NFCC.

B.31.2.2 Application of Post PSR1 Reviews

Per the National Research Council of Canada, the major changes in the NFCC from 2005 to 2010 are summarized as follows [B.31-26]:

- Adjacent buildings or facilities must now be protected from fires originating from demolition or construction sites. Requirements for fire safety plans and fire department access to sites were improved. Specific requirements on the commissioning and decommissioning of standpipe systems, as well as restrictions on rooftop bitumen kettle placement, have been added.

  These changes are either not applicable to Pickering NGS, or are addressed via OPG Plan P-PLAN-09100-00001 R003, "Pickering Fire Safety Plan" [B.31-27]. Per [B.31-27]: "The Fire Safety Plan meets the requirements documented in N-PROG-RA-0012, "Fire Protection", in CAN/CSA N293-07, "Fire Protection for CANDU Nuclear Power Plants" (Fire Protection Plan, A6 Operation), and in the National Fire Code of Canada 2010, Section 2.8.2 Fire Safety Plan".

- A new occupancy classification for residential care facilities has been created (Group B3 occupancy) that relaxes requirements for smaller care occupancies having a limited number of occupants. These items are shared with the National Building Code of Canada, and are not applicable to Pickering NGS.

- New construction, sprinkler, emergency power and fire alarm requirements were added. These items are shared with the National Building Code of Canada, and have been addressed separately for PSR2 as part of that review.

- To draw a clear line between the roles of the NBCC and the NFCC, building design requirements presently in the NFCC were moved to the NBCC (except for spill control measures). Appropriate cross-referencing between the two codes was added. This does not affect the requirements.

- Limits to quantities of flammable and combustible liquids stored within buildings have been updated, including addition of new passive and active fire protective measures. Changes dealing with leak detection and monitoring, as well as handling of certain dangerous goods, have been introduced. Existing requirements relating to the detection and monitoring of storage tanks, sumps, and piping systems containing flammable and combustible liquids were also revised and new ones added.

  As outlined in NK38-REP-03680-10188 R001 [B.31-25], gaps identified for the Darlington ISR on these items related to referencing newer standards/guides, specifying different valve/pipe identification requirements, and minor changes to requirements in the 2010 NFCC versus the 2005 version. These items are not safety significant.

Based on the above, there are no Pickering NGS safety significant findings (PSR2 gaps) against the 2010 version of the NFCC. The changes to NFCC 2010 are largely incremental in nature due to minor improvements in knowledge and the addition of clarifications, and do not impact the overall adequacy of the previous Pickering Units 1,4 and Units 5-8 reviews against the 2005 version of the NFCC (which are not impacted by Pickering NGS operation past 2020).

It is noted that if a fundamental change in understanding occurs that could have a negative impact on safety, this is addressed in a timely fashion through Industry Operating Experience (OPEX). CSA N293 addresses specific nuclear fire protection design, operational and performance requirements, and a review against the latest version of N293-12 (including design-related aspects) is addressed as part of PSR2. In addition, Nuclear Oversight conducts an annual audit to assess Fire Protection provisions in accordance with CSA N293 Appendix E, "Fire Inspections and Audits" to provide assurance that the inspection requirements of the NFCC, including ITM activities, are being met pursuant to the Nuclear Power Reactor Operating License [B.31-27].

Further, OPG has a major fire protection program assessing and addressing any fire protection findings at Pickering NGS. A sampling of recent work includes:

- OPG Report NK30-REP-71400-00018 R000, "Fixed Fire Protection Systems Inspection, Testing and Maintenance" [B.31-28].

- OPG Report NA44-REP-71400-00021 R000, "Pickering A Fixed Fire Protection Systems Inspection, Testing, and Maintenance Code Compliance Report" [B.31-29].

- OPG Report, NA44-REP-71400-00027 R000, "Pickering NGS 014 Compliance with CSA N293-07, Fire Protection for CANDU Nuclear Power Plants" [B.31-30].

- OPG Report, NA44-REP-71400-00023 R000, "Fire Safe Shutdown Analysis - Pickering A Nuclear Generating Station" [B.31-31].

- OPG Report, NA44-REP-71400-10003 R001, "Fire Hazard Assessment - Pickering A Nuclear Generating Station" [B.31-32].

- OPG Report, NK30-REP-71400-00033 R000, "Pickering NGS 058 Compliance with CSA N293-07, Fire Protection for CANDU Nuclear Power Plants" [B.31-33].

- OPG Report, NK30-REP-71400-00001 R002, "Fire Safe Shutdown Analysis - Pickering B Nuclear Generating Station" [B.31-34].

- OPG Report, NK30-REP-71400-10002 R002, "Fire Hazard Assessment - Pickering B Nuclear Generating Station" [B.31-35].

- OPG Report, NA44-REP-71400-00034 R000, "Pickering A Buried Piping Third Party Review" [B.31-36].

- OPG Letter, NA44-CORR-00531-07592 R000, "Submission of Fire Protection Independent Third Party Code Compliance Review for Pickering A Firewater Pipe Replacement Project 13-80069" [B.31-37].

- OPG Letter, NK30-CORR-00531-06032 R000, "Pickering B - Response to CNSC Action Item 20118-2289 - Type II Inspection of Fire Protection Water Supply Systems" [B.31-38].

- OPG Letter, NA44-CORR-00531-06269 R000, "Pickering "A" - Installation of Diesel Engine Driven Fire Pumps (MEC 91665)" [B.31-39].

The above demonstrates that Pickering NGS has an extensive fire management program that is continually assessed for compliance against modern standards and any issues are addressed as part of the program.

B.31.3 Compliance Summary for Pickering PSR2

There is one PSR2 gap for NFCC (2010) [B.31-1], related to piping for flammable or combustible liquids at building entrances. The gap is related to Safety Factor 1 (Plant Design). As discussed in Section B.31.2.1, this issue is identified as a PSR2 gap in OPG Report P-REP-03680-00024 R000, "Pickering 5-8 Continued Operations Plan Review in Support of PNGS Periodic Safety Review 2". Therefore, a duplicate gap under NFCC (2010) has not been created.

B.32 CSA N290.8-15, "Technical Specification Requirements for Nuclear Power Plant Components"

B.32.1 Background

The following text from the Preface and Scope of CSA N290.8-15 [B.32-1] provides a brief overview of the purpose of this Standard and the requirements expressed therein:

> *This Standard is intended to ensure that technical specifications used to procure components are concise, consistent, and complete (i.e., identify all of the technical requirements and acceptance criteria). This Standard is not intended to add new requirements, codes, and standards, or interpretations to the component's design basis.*
>
> *This Standard has been written as a general standard for specifying components that will be installed in nuclear power plants. It establishes the requirements for design, procurement, installation, commissioning/testing, operation, maintenance, packaging, shipping that are to appear in the technical specifications for components.*
>
> *This Standard is one of a series of standards on reactor control systems, safety systems, and instrumentation for nuclear power plants.*
>
> *The CSA N-Series of Standards provides an interlinked set of requirements for the management of nuclear facilities and activities. CSA N286 provides overall direction to management to develop and implement sound management practices and controls, while the other CSA nuclear Standards provide technical requirements and guidance that support the management system. This Standard works in harmony with CSA N286 and does not duplicate the generic requirements of CSA N286; however, it may provide more specific direction for those requirements…*
>
> *The Standard:*
>
> a) *provides a consistent approach across the industry to produce specifications for components used in normal operation, anticipated operational occurrences (AOOs), and design basis accidents (DBAs)...*
>
> b) *provides a common set of attributes to be used when specifying component requirements related to plant design requirements;*
>
> c) *utilizes the product specific knowledge of the industry to provide common criteria for specifying technical requirements;*
>
> d) *provides a common set of attributes for use when specifying requirements for analysis, testing, design, manufacturing, and associated documentation to demonstrate components can meet their design requirements; and*
>
> e) *is not intended to require update of existing specifications.*

CSA N290.8-15 [B.32-1] is relevant to Safety Factor 1 (Plant Design).

CSA N290.8-15 is the first edition of this standard [B.32-1]. According to the N290.8-15 CSA Impact Statement and Public Review Notice [B.32-2]:

> *This Standard provides requirements and guidance on the content of technical specifications. The value of this standard is dependent on its implementation by operators…*
>
> *The Standard assumes that organizations preparing technical specifications has and maintains a quality assurance program that complies with the requirements of CSA N286-12.*
>
> *It is not necessary or expected that the requirements of this Standard would be applied retroactively to existing specifications that have been previously used to procure safety related components for use in a nuclear power plant (NPP).*
>
> *The Standard does not apply to the preparation of technical specifications for catalogue items that can be purchased without a detailed technical specification prepared by or on behalf of a NPP. Neither does the Standard apply to the preparation of technical specifications for raw material (plate steel, consumable materials, conduit etc.), services, and civil structures.*
>
> *The Standard does not provide requirements for specifications that are "strictly of a commercial nature" (i.e., Liability, warranty, escalation, insurance, liquidated damages, quantity, cancellation, etc.).*

Compliance with CSA N290.8-15 [B.32-1] is not currently a licence requirement for Pickering NGS (in accordance with PROL 48.02/2018) per the R04 Pickering Licence Conditions Handbook [B.32-3].

As identified in Pickering NGS PSR2 Basis Document [B.32-4], the Pickering PSR2 review of CSA N290.8-15 is a High Level review. For a PSR2 High Level review, the degree of conformance with clauses or groups of clauses in the Law, Regulation, Code or Standard (L/R/C/S) is demonstrated by supporting evidence stating whether the intent of the requirements stipulated in the requirement document is met. The review identifies Compliances and Gaps, where required, as defined below:

- <u>Compliance:</u> Compliance indicates that the intent of the safety requirement is met.
- <u>Gap</u>: A Gap indicates that the intent of the safety requirement is not met.

B.32.2 Compliance Assessment for Pickering PSR2

B.32.2.1 Application of PSR1 Reviews

CSA N290.8 was not reviewed as part of PSR1 as the document did not exist at the time that the previous Darlington and Pickering B Integrated Safety Reviews, and the Pickering A Return to Service assessments, were performed. A high level review of CSA N290.8-15 [B.32-1] is provided in Section B.32.2.2 below.

B.32.2.2 Application of Post PSR1 Reviews

According to the N290.8-15 CSA Impact Statement and Public Review Notice [B.32-2], the following is a "Summary of Significant Features" of N290.8:

- *Feature 1: This new Canadian Standard provides requirements for specifications used to procure components (or assemblies) for use in nuclear safety related applications within a Nuclear Power Plant (NPP).*
- *Feature 2: This Standard provides guidance to promote that technical specifications for components have been vetted with available industry representatives (suppliers) thus ensuring that suppliers are able to supply the component specified.*
- *Feature 3: This Standard promotes a consistent approach for use across the industry.*
- *Feature 4: This Standard identifies critical attributes necessary to promote that components perform their intended function(s) are listed within the technical specification(s) used to procure those components.*
- *Feature 5: This Standard recommends the preparer to exclude references which are not relevant to procurement, to avoid burdening the vendor with unnecessary documentation. This enables the vendors to be more efficient and ultimately avoid unnecessary cost.*
- *Feature 6: The Standard promotes that technical specifications include requirements which define the interface between the component and other components within NPP system.*
- *Feature 7: The Standard promotes that appropriate Codes and Standards are referenced within the technical specification.*
- *Feature 8: The Standard promotes that all appropriate documentation defining the pedigree of the component will be supplied.*
- *Feature 9: Annex A of the Standard provides informative guidance for use in preparing technical specification data sheets. Annex A also provides sample tech spec data sheets for a variety of components.*
- *Feature 10: Annex B of Standard provides informative guidance on the selection and inclusion of graded quality assurance requirements that may be included within the technical specifications as an alternative to the now withdrawn CSA Z299 series.*

A compliance review against CSA N290.8-15 [B.32-1] was not undertaken as part of previous PSR1 reviews and the following High Level assessment has been completed. In the review below, the degree of conformance with clauses or groups of clauses in the L/R/C/S is assessed for Pickering NGS by reference to supporting evidence stating whether the intent of the requirements stipulated in the L/R/C/S is met.

Due to the nature of N290.8-15, it is important to clearly state the intent of this standard within the context of PSR2.

1) CSA N290.8-15 is not intended to be applied retroactively

   The Impact Statement and Public Review Notice for N290.8-15 [B.32-2] includes explicit statements that the standard is not intended to be applied retroactively to previously issued specifications.

   For the purposes of PSR2, demonstrating whether the intent of the standard is met is determined by reviewing existing procedures that would be used to prepare specifications going forward.

2) CSA N290.8-15 is not a source of component-specific technical requirements

   As stated in the Preface section of N290.8-15 [B.32-1], the intent of this standard is to ensure that technical specifications used to procure components are concise, consistent, and complete. Technical requirements for a given component will vary on a case-by-case basis and be specified in accordance with the design basis for the corresponding system (e.g., per the corresponding system Design Manual). N290.8-15 provides direction on the type of requirements that need to be identified in a technical specification, but is not a source of specific technical requirements.

   For the purposes of PSR2, compliance is assessed by determining whether existing procedures governing the preparation of specifications provide direction for staff to include the information specified by N290.8-15.

Governing procedures for the preparation of technical specifications are N-PROC-MP-0059, "Preparation, Review, and Approval of Engineering Specifications" [B.32-5] and N-PROC-MP-0089, "Design Specifications, Design Reports and Overpressure Protection Reports" [B.32-6]. The majority of technical specifications will be prepared in accordance with N-PROC-MP-0059 [B.32-5] as this procedure is written such that it is not discipline-specific (e.g., procedure can be applied to procurement of mechanical, civil, electrical, instrumentation and control components, or software components). Only a small sub-set of mechanical components that perform a pressure boundary function require a technical specification to be prepared in accordance with N-PROC-MP-0089 [B.32-6].

Procedures and templates used to prepare specifications are written at a high level such that they can be readily used for components covering a range of technical disciplines (i.e., N-PROC-MP-0059 [B.32-5]) and/or a range of components within an individual technical discipline (i.e., N-PROC-MP-0059 [B.32-5] and N-PROC-MP-0089 [B.32-6]). Thus, the determination of whether the intent of a particular section of N290.8-15 is satisfied is primarily made by confirming that OPG governing procedures (and associated document templates) prompt the preparer of the specification to include the type of information specified in N290.8-15. Where appropriate, activities performed by Supply Chain and/or Procurement Engineering staff are considered as part of the PSR2 Review.

CSA N290.8-15 Clause	**PSR2 Review**	**Compliant or Gap**
0 Introduction	There are no requirements specified. The introduction describes the purpose of CSA N290.8-15.	N/A
1 Scope	There are no requirements specified. Sets context.	N/A
2 Reference Publications	There are no requirements specified. Describes the publications that CSA N290.8-15 refers to.	N/A
3 Definitions and Abbreviations	There are no requirements specified. Defines various words or phrases, or acronyms, used in CSA N290.8-15.	N/A
4 Preparation of Technical Specifications	There are no requirements specified. Heading only.	Compliant
4.1 Procurement *The technical specification should identify any unique procurement requirements that are not addressed by standard commercial or procurement provisions.*	The procurement of new items is governed by OPG-PROC-0060, "Requisitioning Items and Services" [B.32-7]. This procedure directs Supply Chain and Procurement Engineering to complete the following key activities: 1) Requisitioner identifies a suitable CAT ID in accordance with N-PROC-MM-0008, "Catalogue Information: Create, Maintain, and Replenish" [B.32-8]. 2) As part of setting a CAT ID to "Ready" status, a pre-purchase technical review is performed by Supply Chain staff and where appropriate, Procurement Engineering staff. Reviews by Procurement Engineering staff are performed in accordance with N-PROC-MP-0098, "Procurement Engineering Activities" [B.32-9]. 3) Once a CAT ID has been set to "Ready" and associated Material Request has been approved, OPG-PROC-0060 [B.32-7] directs Supply Chain staff to procure the component in accordance with OPG-PROC-0058, "Procurement Activities" [B.32-10]. The activities described above ensure that standard commercial or procurement provisions are translated into procurement requirements. As part of performing these activities, Supply Chain and Procurement Engineering staff will seek additional information to ensure unique procurement requirements (i.e., component-specific technical requirements) are documented and identified. Depending on the nature of the component that is being procured, these unique requirements are documented in an Engineering Specification in accordance with N-PROC-MP-0059, "Preparation, Review, and Approval of Engineering Specifications" [B.32-5] or a Design Specification in accordance with N-PROC-MP-0089, "Design Specifications,	Compliant

CSA N290.8-15 Clause	PSR2 Review	Compliant or Gap
	Design Reports and Overpressure Protection Reports" [B.32-6].	
4.2 Catalogue Component This covers: • Consideration of whether a technical specification is required if there exists a supplier's catalogue component that meets end-use requirements. • Identification of additional modifications/tests required for a supplier's catalogue components to satisfy end-use requirements.	OPG governance dictates that technical specifications will be prepared even if there exists a supplier's catalogue component that meets end-use requirements. This satisfies the intent of the requirement as the organization is not precluded from using technical specifications in these circumstances. Specifically, components are procured either through a Request for Quotation (RFQ) or a Request for Proposal (RFP) in accordance with OPG-PROC-0058 [B.32-10]. The RFQ/RFP package identifies all requirements needed to procure the component and makes reference to an Engineering Specification or a Design Specification.	Compliant
4.3 References Codes, Standards, and Generic Specifications This covers: • Identification of applicable Codes, Standards, and generic specifications. • Identification of year-date or revision number for Standards referenced in the specification. • Where applicable, identification of acceptable or required deviations from referenced Codes, Standards, or generic specifications.	Requirements related to applicable Codes, Standards, and generic specifications are documented in an Engineering Specification or a Design Specification. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019, "Engineering Specification" [B.32-11]. Section 4.0 of N-TMP-10019 prompts the preparer to identify applicable Codes and Standards for the component [B.32-11]. In addition, Section 1.2 of N-PROC-MP-0059 requires the preparer to determine if there is a generic specification available which is adequate to define the requirements for the component [B.32-5]. Design Specifications are prepared for components performing a pressure boundary function in accordance with N-PROC-MP-0089 [B.32-6] using N-TMP-10190, "Design Specification" [B.32-12] or N-FORM-11612, "Valve Specification Data Sheet – Nuclear Class 1, 2, or 3 Valves" [B.32-13]. Appendix A of N-TMP-10190 requires the preparer to identify applicable Codes and Standards for the component [B.32-12]. Item 3 in N-FORM-11612 prompts the preparer to identify applicable Codes and Standards [B.32-13].	Compliant

CSA N290.8-15 Clause	PSR2 Review	Compliant or Gap
4.4 Component Standardization This covers: • Providing direction to select catalogue components if such components are determined to meet all technical requirements. • Minimization of inventory and maintenance costs by using organization's component standardization practices (e.g., use of previously purchased components that satisfy requirements).	Components are procured in accordance with OPG-PROC-0060 [B.32-7]. Step 1.1.2 of OPG-PROC-0060 [B.32-7] prompts the requisitioner to ensure technical requirements are identified prior to initiating a requisition. Components that are to be procured are assigned CAT IDs in accordance with N-PROC-MM-0008 [B.32-8]. Section 1.1.2 of N-PROC-MM-0008 [B.32-8] requires the requestor to complete a thorough search of the Master Materials Catalog and/or Standard Materials Catalog to determine if the required item already has a CAT ID. Once a CAT ID has been assigned, Appendix A of OPG-PROC-0060 [B.32-7] prompts the requisitioner to order the component through the OPG Web Catalogue, if possible. In addition, procedures governing the preparation of technical specifications direct staff to minimize the use of custom specifications as noted below: • Section 1.1 of N-PROC-MP-0059 [B.32-5] directs staff to maximize the use of generic Engineering Specifications. • Section 1.5 of N-PROC-MP-0089 [B.32-6] prompts the preparer to determine if the required document has previously been prepared.	Compliant
4.5 Supplier Capability *The preparer should consider the capability of the supplier community when preparing a technical specification so that gaps between the capability of available components and the critical characteristics required by the NPP application are addressed.*	Supplier capabilities are taken into consideration during the preparation of Engineering Specifications and Design Specifications. For Engineering Specifications, Section 1.2.3 of N-PROC-MP-0059 directs the preparer to ensure that there is sufficient information provided to enable vendors to design, manufacture, or supply components that meet the specified requirements [B.32-5]. In addition, Section 1.3 of N-PROC-MP-0059 specifies that Engineering Specifications are reviewed by Strategic Sourcing and Supply Planning and Procurement to review the manufacturing processes that have been specified and ensure alignment with good industry and business practices [B.32-5]. Only suitably qualified vendors on OPG's Approved Suppliers List would be asked to supply and/or procure these components [B.32-10]. Design Specifications, in accordance with N-PROC-MP-0089 [B.32-6] for pressure boundary components, must comply with the ASME Boiler and Pressure Vessel Code (BPVC) [B.32-14]. Only vendors on OPG's Approved Suppliers List qualified as being capable of performing pressure boundary work would be asked to supply and/or procure these components [B.32-10].	Compliant

CSA N290.8-15 Clause	PSR2 Review	Compliant or Gap
4.6 Units *The technical specification should maintain a single system of measurement consistent with that used in the applicable NPP and, when multiple units are used, the sequence of units of measure should be consistent.*	Pickering NGS is designed and operated with a standardized set of units of measurement that are reflected in all plant documentation. The development of technical specifications include extracting relevant information from existing plant documentation. Thus, the process of preparing a technical specification is structured such that requirements are identified in accordance with the units of measurement used by the station.	Compliant
4.7 Supplier Submissions *The technical specification shall require that the supplier list all* *a) Assumptions;* *b) Exceptions; and* *c) Identification and description of all digital items.*	The RFQ/RFP process described in OPG-PROC-0058 [B.32-10] prompts the supplier to identify any conditions to their responses or exceptions to requirements specified by OPG. Any conditions or exceptions noted by the supplier are considered in the bid evaluation process. However, OPG-PROC-0058 does not include explicit direction for the supplier to be required to identify/describe the use of all digital items in their equipment. The situation of interest is where a RFP/RFQ is issued for equipment that is not expected to include any digital items, but the supplier's design includes digital items. If the use of digital items is identified in advance of issuing the RFP/RFQ, applicable requirements would be specified in an Engineering Specification (per N-PROC-MP-0059 [B.32-5]) or a Design Specification (per N-PROC-MP-0089 [B.32-6]). However, if the equipment is not expected to contain any digital items, the use of these procedures would not result in a requirement for the supplier to self-identify whether their product contains any digital items. As requirements for supplier self-identification are not in OPG governance, this is identified as **PSR2 CSA N290.8-15 Gap #1**.	Gap
4.8 Design The technical specification shall include all applicable technical requirements and invoke the applicable referenced Codes and Standards.	Component-specific requirements are identified in accordance with the design requirements for the system that the component is to be installed in. Design requirements (e.g., physical limitations, functional requirements, performance requirements, etc.) are documented in an Engineering Specification or a Design Specification. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Sections 4.0 and 5.0 of N-TMP-10019 [B.32-11] prompt the document preparer to include applicable design requirements. Design Specifications are prepared for components that perform a pressure boundary function in accordance with N-PROC-MP-0089 [B.32-6] using N-TMP-10190 [B.32-12] or N-FORM-11612 [B.32-13]. Section 2.1 and Appendix A of N-TMP-10190 [B.32-12] requires the preparer of the document to include applicable design requirements. Similarly, N-FORM-11612 [B.32-13] require the preparer of the document to	Compliant

CSA N290.8-15 Clause	PSR2 Review	Compliant or Gap
	include applicable design requirements. Additional direction is provided in Sections 1.2.5 and 1.2.6 of N-PROC-MP-0089 [B.32-6] for the preparer to ensure that all applicable technical requirements are captured in the Design Specification or Valve Specification Data Sheet.	
4.9 Component Interaction If the component being procured is part of an assembly, the technical specification should identify requirements for the interactions between individual components in the assembly. Where applicable, these requirements include: • Description of interaction between individual components in an assembly. • Identification of interface requirements (physical attributes and functional attributes). • Identification of individual component performance requirements and acceptance criteria.	Component interaction requirements are documented in an Engineering Specification or a Design Specification, depending on the components that are to be procured. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Sections 4.0, 5.0, and 6.0 require the preparer to include requirements related to component interaction within an assembly. Design Specifications are prepared for components performing a pressure boundary function in accordance with N-PROC-MP-0089 [B.32-6] using N-TMP-10190 [B.32-12] or N-FORM-11612 [B.32-13]. Both N-TMP-10190 and N-FORM-11612 require the preparer to list all of the subject components and their associated requirements.	Compliant
4.10 Free Issue Material and Services *The technical specification may provide the supplier with information on the control of free issue material and services that will be made available by the operating organization.*	N-PROC-MP-0059 [B.32-5] and N-PROC-MP-0089 [B.32-6] do not prompt the preparer of a technical specification to include information regarding the control of free issue material and services. The control of free issue material is maintained in accordance with OPG-PROC-0060, "Requisitioning Items and Services" [B.32-7]. Existing OPG processes (i.e., OPG-PROC-0060 [B.32-7]) meet the intent of this requirement as N290.8-15 does not require the technical specification to be the governing document for the control of free issue material and services. The use of OPG-PROC-0060 meets the intent of the requirement for the use of free issue material.	Compliant
4.11 Operating Organization Supplied Design *In instances where portions of the design are to be supplied by the operating organization, the*	The intent of this requirement is to ensure that the division of responsibilities between OPG and its supplier for the completion of design activities is clearly documented. For activities being performed under an Engineering, Procurement, and Construction (EPC) agreement, Section 1.2	Compliant

CSA N290.8-15 Clause	PSR2 Review	Compliant or Gap
technical specification shall identify the portions of the design to be supplied and identify the supplier's responsibilities for integrating, and implementing the portions supplied by the operating organization.	of N-STD-MP-009, "Contractor/Owner Engineering Interface and Oversight" [B.32-15] dictates that the interface requirements between OPG and its supplier must be formally documented. N-COI-00120-00001, "Contractor/Owner Interface Requirements for Nuclear" [B.32-16] is used as a basis for preparing interface requirements which may be a standalone document or incorporated into other documentation such as an Engineering Specification. For activities being performed outside of an EPC agreement, arrangements for design services are made in accordance with OPG-PROC-0060 [B.32-7].	
4.12 QA Requirements *The technical specification shall identify the QA requirements applicable to the component and/or assembly to ensure that it meets all of its requirements.*	QA requirements for a component and/or assembly are documented in an Engineering Specification or a Design Specification. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Section 3.0 of N-TMP-10019 [B.32-11] requires the document preparer to identify applicable QA requirements. Design Specifications are prepared for components performing a pressure boundary function in accordance with N-PROC-MP-0089 [B.32-6] using N-TMP-10190 [B.32-12] or N-FORM-11612 [B.32-13]. Both N-TMP-10190 and N-FORM-11612 are structured to identify QA requirements applicable to the ASME BPVC. Additionally, Sections 1.2.5 and 1.2.6 of N-PROC-MP-0089 require the preparer of the specification to include any additional QA requirements that apply to the subject component [B.32-6]. Once completed, Engineering Specifications and Design Specifications are included in a RFP/RFQ package. Activities related to the RFP/RFQ process are performed in accordance with OPG-PROC-0058 [B.32-10], which provides direction to ensure that applicable QA requirements are identified in the documentation package provided to potential suppliers.	Compliant
4.13 Documentation Requirements The technical specification shall provide a list of all engineering documents required to be provided by the supplier to design, install, operate, commission and maintain the component. Where applicable, the required documentation may include:	Documentation requirements are included in an Engineering Specification or a Design Specification. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Section 10.0 of N-TMP-10019 requires the preparer of the document to identify all of the documents required to be provided by the supplier [B.32-11]. Design Specifications are prepared for components performing a pressure boundary function in accordance with N-PROC-MP-0089 [B.32-6] using N-TMP-10190 [B.32-12] or N-FORM-11612 [B.32-13]. Sections 1.2.5 and 1.2.6 of N-PROC-MP-0089 require the preparer to add sections or appendices to the form/template in order to identify	Compliant

CSA N290.8-15 Clause	PSR2 Review	Compliant or Gap
• Engineering documentation. • Installation manuals. • Commissioning/ operation manuals. • Maintenance manuals. • History files. • Other documentation as required.	documentation requirements specific to the subject component [B.32-6].	
4.14 Reliability and Maintainability Reliability and maintainability requirements shall be identified in a technical specification, including the corresponding operations and maintenance activities that shall be performed following component installation in order to demonstrate compliance with the specified requirements.	Reliability and maintainability requirements are documented in an Engineering Specification or a Design Specification. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Sections 5.0 and 6.0 of N-TMP-10019 [B.32-11] require the preparer of the document to identify applicable reliability and maintainability requirements. Design Specifications are prepared in accordance with N-PROC-MP-0089 [B.32-6] using N-TMP-10190 [B.32-12] or N-FORM-11612 [B.32-13]. Sections 1.2.5 and 1.2.6 of N-PROC-MP-0089 [B.32-6] require the preparer of the document to add sections or appendices to the form/template in order to identify applicable reliability and maintainability requirements.	Compliant
4.15 Testing Required testing activities to support the procurement of a component shall be identified in a technical specification. These requirements may include: • Identification of testing requirements for the component that is being procured. • Identification of applicable type tests and/or production tests.	Testing requirements are documented in an Engineering Specification or a Design Specification. Component-specific testing requirements are identified based on safety credits for the corresponding plant system and the location where the component is to be installed (e.g., if a component is going to be installed in a system important to safety in a location that is subjected to harsh environmental conditions, as determined by the Environmental Qualification Room Conditions Manual, appropriate testing requirements for environmental qualification would be included in the specification). Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Section 6.0 of N-TMP-10019 [B.32-11] requires the preparer of the document to identify applicable testing requirements. Design Specifications are prepared for components performing a pressure boundary function in accordance with N-PROC-MP-0089 [B.32-6] using N-TMP-10190 [B.32-12] or	Compliant

CSA N290.8-15 Clause	PSR2 Review	Compliant or Gap
	N-FORM-11612 [B.32-13]. Both N-TMP-10190 and N-FORM-11612 require the preparer to identify testing requirements in accordance with the applicable sections of the ASME BPVC. Additionally, Sections 1.2.5 and 1.2.6 of N-PROC-MP-0089 [B.32-6] prompt the preparer of the document to add sections or appendices to the form/template in order to identify any additional testing requirements.	
4.16 Marking and Labelling *The technical specification shall identify the marking and labelling requirements consistent with the applicable Codes and Standards for the component being specified.*	Marking and labelling requirements are documented in an Engineering Specification or a Design Specification. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Section 7.0 of N-TMP-10019 [B.32-11] requires the preparer of the document to identify applicable marking/labelling requirements. Design Specifications are prepared for components performing a pressure boundary function in accordance with N-PROC-MP-0089 [B.32-6] using N-TMP-10190 [B.32-12] or N-FORM-11612 [B.32-13]. Both N-TMP-10190 and N-FORM-11612 require the preparer to identify marking/labelling requirements in accordance with the applicable sections of the ASME BPVC. Additionally, Sections 1.2.5 and 1.2.6 of N-PROC-MP-0089 [B.32-6] prompt the preparer of the document to add sections or appendices to the form/template in order to identify any additional marking/labelling requirements.	Compliant
4.17 Cleanliness and Foreign Material Exclusion (FME) Requirements Where applicable, the technical specification shall identify requirements related to cleanliness and foreign material exclusion. These requirements may include : • Listing of FME covers, transportation supports, or other temporary items. • Requirements to control substances in contact with components and to prevent banned substances entering the plant where applicable.	Cleanliness and FME requirements are documented in an Engineering Specification or a Design Specification. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Sections 3.0, 5.0, and 8.0 of N-TMP-10019 [B.32-11] require the preparer of the document to identify requirements related to cleanliness and FME exclusion. Design Specifications are prepared for components performing a pressure boundary function in accordance with N-PROC-MP-0089 [B.32-6] using N-TMP-10190 [B.32-12] or N-FORM-11612 [B.32-13]. Both N-TMP-10190 and N-FORM-11612 require the preparer of the document to identify requirements for cleanliness and FME in accordance with the applicable sections of the ASME BPVC. Additionally, Sections 1.2.5 and 1.2.6 of N-PROC-MP-0089 prompt the preparer of the document to add sections or appendices to the form/template in order to identify any additional cleanliness or FME requirements.	Compliant

CSA N290.8-15 Clause	**PSR2 Review**	**Compliant or Gap**
4.18 Lifting Points *In instances where the operating organization has special lifting constraints or requirements, the technical specification shall identify these requirements.*	Special lifting constraints or requirements are documented in an Engineering Specification or a Design Specification. These are a specific type of design requirement, as the component would need to be designed and fabricated to facilitate any lifting activities required to support installation or maintenance of the component. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Section 5.0 of N-TMP-10019 [B.32-11] requires the preparer of the document to identify applicable design and fabrication requirements. Design Specifications are prepared for components performing a pressure boundary function in accordance with N-PROC-MP-0089 [B.32-6] using N-TMP-10190 [B.32-12] or N-FORM-11612 [B.32-13]. Sections 1.2.5 and 1.2.6 of N-PROC-MP-0089 [B.32-6] require the preparer of the document to add sections or appendices to the form/template in order to identify any special lifting requirements.	Compliant
4.19 Human Factors *The technical specification shall identify any applicable human factors requirements.*	Human factors requirements are a specific type of design requirement that would be documented, if applicable, in an Engineering Specification or a Design Specification. N-PROC-MP-0090, "Modification Process" [B.32-17] provides direction to identify the required design inputs from a human factors perspective. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Sections 4.0 and 5.0 of N-TMP-10019 [B.32-11] require the document preparer to include applicable design requirements. Design Specifications are prepared for components performing a pressure boundary function in accordance with N-PROC-MP-0089 [B.32-6] using N-TMP-10190 [B.32-12] or N-FORM-11612 [B.32-13]. Section 2.1 and Appendix A of N-TMP-10190 [B.32-12] requires the preparer to include applicable design requirements. Similarly, N-FORM-11612 [B.32-13] requires the preparer to include applicable design requirements. Additional direction is provided in Sections 1.2.5 and 1.2.6 of N-PROC-MP-0089 [B.32-6] for the preparer of the document to ensure that all applicable technical requirements are captured in the Design Specification or Valve Specification Data Sheet.	Compliant

CSA N290.8-15 Clause	PSR2 Review	Compliant or Gap
4.20 Fire Protection and Hazards *The technical specification shall identify any applicable fire protection and hazard requirements.*	N-PROC-MP-0090, “Modification Process” [B.32-17] provides direction to identify the required design inputs from a fire protection perspective. When N-PROC-MP-0090 [B.32-17] determines fire protection requirements are applicable for a specific component, appropriate requirements would be documented in an Engineering Specification or a Design Specification. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Sections 4.0 and 5.0 of N-TMP-10019 [B.32-11] require the document preparer to include applicable design requirements, including applicable Laws, Regulations, Codes and Standards (specific section, step, or clause of the document, including the applicable edition of the code). Therefore, design requirements related to fire protection would be specified in accordance with relevant Codes and Standards, such as the National Fire Code of Canada [B.32-18] and CSA N293-07, “Fire Protection for CANDU Nuclear Power Plants” [B.32-19]. Design Specifications are prepared for components performing a pressure boundary function in accordance with N-PROC-MP-0089 [B.32-6] using N-TMP-10190 [B.32-12] or N-FORM-11612 [B.32-13]. Section 2.1 and Appendix A of N-TMP-10190 [B.32-12] requires the preparer to include design requirements based on applicable Laws, Regulations, Codes and Standards. Similarly, N-FORM-11612 [B.32-13] requires the preparer to include design requirements. Additional direction is provided in Sections 1.2.5 and 1.2.6 of N-PROC-MP-0089 [B.32-6] for the preparer of the document to ensure that all applicable technical requirements are captured in the Design Specification or Valve Specification Data Sheet. Therefore, design requirements related to fire protection would be specified in accordance with relevant Codes and Standards, such as the National Fire Code of Canada [B.32-18] and CSA N293-07 [B.32-19].	Compliant
4.21 Operating Conditions The technical specification shall include the most bounding set of operating conditions anticipated during service for the intended application.	The conditions that a component must be designed to operate under are documented in an Engineering Specification or a Design Specification. However, CSA N290.8-15 [B.32-1] is not intended to be used as the basis for identifying the conditions/scenarios a component must be designed to withstand. This would be determined in accordance with the design basis for the system that the component is to be installed in. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Section 5.0 of N-TMP-10019 [B.32-11] requires the document preparer to include the operating conditions that the component must be designed to be capable of withstanding. Design Specifications are prepared for components performing a pressure boundary function in accordance with	Compliant

CSA N290.8-15 Clause	PSR2 Review	Compliant or Gap
	N-PROC-MP-0089 [B.32-6] using N-TMP-10190 [B.32-12] or N-FORM-11612 [B.32-13]. Both N-TMP-10190 and N-FORM-11612 require the preparer of the document to identify the operating conditions that the component must be designed to be capable of withstanding.	
4.22 Component Qualification The technical specification shall identify all requirements needed to provide documented assurance that the component will operate as intended under the conditions dictated by the requirements.	Component qualification requirements, including the completion of required testing/analysis activities and production of corresponding documentation, are documented in an Engineering Specification or a Design Specification. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Sections 4.0, 5.0, 6.0, and 10.0 of N-TMP-10019 [B.32-11] require the preparer of the document to include requirements such that the component can be qualified for its intended use. Design Specifications are prepared for components performing a pressure boundary function in accordance with N-PROC-MP-0089 [B.32-6] using N-TMP-10190 [B.32-12] or N-FORM-11612 [B.32-13]. N-FORM-11612 [B.32-13] and Section 3.0 of N-TMP-10190 [B.32-12] require the preparer to include applicable component qualification requirements. Additionally, Sections 1.2.5 and 1.2.6 of N-PROC-MP-0089 require the preparer to add sections or appendices to the form/template in order to identify documentation requirements specific to the subject component [B.32-6].	Compliant
4.23 Digital Items Requirements related to the use of digital items shall be included in a technical specification. Where applicable, the technical specification shall address the following requirements: • Identification of whether the use of a digital item is acceptable. • If it is acceptable to use a digital item, identification of documentation required to enable qualification to CSA N290.14.	Per Section 3 of CSA N290.8-15 [B.32-1], a digital item encompasses pre-developed software, custom software, software engineering tools and digital hardware. However, CSA N290.8-15 is not intended to be used as a source of requirements for the use of digital items; such requirements would be specified in accordance with the design basis for the system that the component is to be installed in. Where applicable, requirements related to digital items would be documented in an Engineering Specification in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Section 10.0 of N-TMP-10019 requires the preparer of the document to identify all of the documents required to be provided by the supplier [B.32-11]. Additional requirements regarding the use of digital items would be identified using the governance listed below, that provide direction to document applicable requirements in an Engineering Specification: • N-PROC-MP-0049, "Procurement of Software and Products Containing Software" [B.32-20] • N-PROC-MP-0099, "Development of Real-Time Process Computing System" [B.32-21]	Compliant

CSA N290.8-15 Clause	PSR2 Review	Compliant or Gap
	• N-STI-69000-10013, "Computer System Requirements and Design" [B.32-22] • N-INS-69000-10002, "Computer Spare Parts and Other Electronic Components Acquisition by Computers and Control Design Department" [B.32-23]. A separate review has been performed in support of PSR2 to assess compliance with CSA N290.14, "Qualification of Digital Hardware and Software for Use in Instrumentation and Control Applications for Nuclear Power Plants" [B.32-24].	
4.24 Cyber Security *The technical specification shall include the applicable cyber security requirements from CSA N290.7.*	Where applicable, cyber security requirements are identified in accordance with N-PROC-MP-0049 [B.32-20], which directs staff to prepare an Engineering Specification. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Sections 3.0, 4.0, 5.0, 6.0, and 10.0 of N-TMP-10019 [B.32-11] require the preparer of the document to identify applicable design requirements, which includes cyber security requirements. A separate review [B.32-25] of compliance with CSA N290.7 has been performed, which meets the intent of PSR2. Due to security and confidentiality constraints, the findings of this review will not be discussed in PSR2.	Compliant
5 Instrumentation and Control Components This section of CSA N290.8-15 covers the identification of discipline-specific requirements not explicitly stated in Section 4. This includes: • Design requirements. • Functional requirements. • Performance requirements. • Testing requirements.	Per CSA N290.8-15 [B.32-1], Section 5 is intended to be used in conjunction with Section 4 to ensure requirements specific to Instrumentation & Control (I&C) components are identified in technical specifications. CSA N290.8-15 is not intended to be used as a source of technical requirements. Thus, compliance is assessed by determining if applicable OPG procedures and templates direct staff to include the type of information specified in Section 5 of N290.8-15. Specifications for I&C components are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Sections 4.0, 5.0, and 6.0 of N-TMP-10019 [B.32-11] require the preparer of the document to include the type of information specified by N290.8-15.	Compliant
6 Mechanical Components This section of N290.8-15 covers the identification of discipline-specific requirements not	Per CSA N290.8-15 [B.32-1], Section 6 is intended to be used in conjunction with Section 4 to ensure requirements specific to mechanical components are identified in technical specifications.	Compliant

CSA N290.8-15 Clause	PSR2 Review	Compliant or Gap
explicitly stated in Section 4. This includes: • Design requirements. • Functional requirements. • Performance requirements. • Testing requirements. • Component qualification requirements. • Valve requirements. • Pump requirements. • Heat exchanger requirements. • Requirements for Heating, Ventilation and Air Conditioning (HVAC) components. • Requirements for other mechanical components not listed above.	CSA N290.8-15 is not intended to be used as a source of technical requirements. Thus, compliance is assessed by determining if applicable OPG procedures and templates direct staff to include the type of information specified in Section 6 of N290.8-15. Requirements for mechanical components are documented in an Engineering Specification or a Design Specification, as appropriate. Engineering Specifications are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Sections 4.0, 5.0, and 6.0 of N-TMP-10019 [B.32-11] require the preparer of the document to include the type of information specified by N290.8-15. Design Specifications are prepared for components performing a pressure boundary function in accordance with N-PROC-MP-0089 [B.32-6] using N-TMP-10190 [B.32-12] or N-FORM-11612 [B.32-13]. Section 2.1 and Appendix A of N-TMP-10190 [B.32-12] require the preparer of the document to include the type of information specified by N290.8-15 (i.e., identification of applicable requirements per ASME BPVC). Similarly, N-FORM-11612 [B.32-13] requires the preparer to include the type of information specified in N290.8-15. Additional direction is provided in N-PROC-MP-0089 for the preparer of the document to ensure that all applicable technical requirements are captured in the Design Specification or Valve Specification Data Sheet [B.32-13].	
7 Electrical Components This section of N290.8-15 covers discipline-specific requirements not explicitly stated in Section 4. This includes: • Design requirements. • Functional requirements. • Performance requirements. • Testing requirements. • Maintenance requirements.	Per CSA N290.8-15 [B.32-1], Section 7 is intended to be used in conjunction with Section 4 to ensure requirements specific to electrical components are identified in technical specifications. CSA N290.8-15 is not intended to be used as a source of technical requirements. Thus, compliance is assessed by determining if applicable OPG procedures and templates direct staff to include the type of information specified in Section 7 of N290.8-15. Specifications for electrical components are prepared in accordance with N-PROC-MP-0059 [B.32-5] using N-TMP-10019 [B.32-11]. Sections 4.0, 5.0, and 6.0 of N-TMP-10019 [B.32-11] require the preparer of the document to include the type of information specified by N290.8-15.	Compliant

CSA N290.8-15 Clause	PSR2 Review	Compliant or Gap
Annex A (Informative) – Data Sheet Contents	Provides information and does not establish any requirements.	N/A
Annex B (Informative) – National and International Standards Bodies	Provides information and does not establish any requirements.	N/A
Annex C (Informative) – I&C Safety Categories	Provides information and does not establish any requirements.	N/A
Annex D (Informative) – Commercial Guidance	Provides information and does not establish any requirements.	N/A

There are no references to CSA N290.8-15 in OPG governance. Specifically, [B.32-5] does not refer to the standard. However, because the above high level review identified that OPG's governance aligns with all but one of the requirements in the standard, the absence of a reference to the standard does not have any safety significance. Furthermore, CSA N290.8-15 is not currently listed in the Pickering PROL or Licence Conditions Handbook. Therefore, this is not a PSR2 gap.

B.32.3 Compliance Summary for Pickering PSR2

There is one PSR2 CSA N290.8-15 gap which relates to Safety Factor 1 (Plant Design):

1. Clause 4.7 of CSA N290.8-15 mandates that the technical specification requires the supplier to identify and describe all digital items included in their equipment. In the event that the use of digital items is identified by OPG in advance of issuing a Request for Proposal (RFP) or Request for Quotation (RFQ), existing OPG procedures are adequate for ensuring that requirements related to digital items are documented in the technical specification. However, a requirement for a supplier to self-identify whether their product contains any digital items is not reflected in OPG governing documents. This has therefore been identified as a PSR2 gap.

R01	January 12, 2017	S. B. Harvey	Address OPG comments

EXECUTIVE SUMMARY

Ontario Power Generation (OPG) is performing a Periodic Safety Review (PSR) in support of continued operation of Pickering Nuclear Generating Station (NGS) beyond 2020. The PSR (referred to as "PSR2") is a subsequent PSR building on the review basis of earlier OPG Integrated Safety Reviews and other associated assessments.

The Pickering 5-8 Continued Operations Plan (COP) actions with the exception of those related to the Environmental Assessment were reviewed to determine if there were implications for PSR2. PSR2 implications were identified if closed COP actions needed to be re-assessed given the potential to operate Pickering to 2028 rather than 2020, which had been factored into the closure criteria for some COP actions. PSR2 implications were also identified if they were applicable to Pickering Units 1,4. Where there are implications of extended operation, or to Pickering Units 1,4, a PSR2 gap has been identified. These gaps will be considered in the Global Assessment Report.

TABLE OF CONTENTS

Page

1.0 PURPOSE

The Continued Operations Plan (COP) was developed to document the actions that help support continued operation of Pickering 5-8 following a decision not to refurbish the units in 2009. It was developed based on a planned operation to 2020. The COP incorporated actions from the Environmental Assessment (EA) and from the 2009 Integrated Safety Review (ISR) as documented in the Integrated Implementation Plan (IIP) (Reference [1]) and the Global Assessment Report (Reference [2]).

The COP was updated annually from 2010 through to 2015 (References [3] to [8]). A Final Update was provided in December 2015 (Reference [9]).

Per the PSR2 Basis Document [10], the COP actions are being reassessed based on operation to the end of 2028. This approach is consistent with the recommendation from the Canadian Nuclear Safety Commission (CNSC) staff [11].

In Reference [11], the CNSC recommended that OPG utilize the CNSC response to the 2013 version of the COP [12] as the basis for the review, as this version included the most comprehensive COP action listing. The 2013 COP included 95 actions. Seven of the actions were related to the Pickering B Refurbishment EA, and are not within the scope of the Periodic Safety Review 2 (PSR2) (Reference [10]) since they did not originate in the ISR. The remaining 88 actions are addressed in this report.

The purpose of this report is to review the 88 actions from the Pickering 5-8 COP referred to in Reference [12] and as documented in Reference [13] (95 actions minus 7 actions related to the EA) that need to be reassessed for PSR2 based on extended operation to 2028. The 88 COP actions were also reviewed for applicability to Pickering Units 1,4.

2.0 SCOPE

The COP included four sources of actions:

- "E" actions are from the EA (outside the scope of this review);
- "F" actions are from Life Cycle Management Plans or Condition Assessments;
- "G" actions arose from the global assessment; and
- "I" actions originated in the ISR.

This report addresses actions that originated as F, G, and I actions as well as log entries that are related to those actions. The following actions are related to the EA as well as log entries related to the EA and are therefore not included in the scope of PSR2 (Reference [10]):

- E01-01
- E01-01(a)
- E01-02
- E01-2(a)
- E02-01
- E02-01(a)
- E03-01

3.0 METHODOLOGY

In Section 4.0, an assessment is done of each of the 88 Pickering 5-8 COP actions taken directly from Reference [13]. The identification number from the 2015 COP update (Reference [8], [9]) is included. All entries from the 2015 COP update are included in the review. The original wording of the issue is summarized. Impacts of extended operation are identified. Consistent with the PSR2 Basis Document [10], extended operation is assumed to 2028. However, in some cases, systems are needed after shutdown until the units are defueled; where this is the case, the period over which nuclear safety needs to be demonstrated is identified. Implications for Pickering Units 1,4 are also identified.

COP actions that have implications for extended operation or for Pickering Units 1,4 are considered to be PSR2 gaps. The Safety Factors to which these gaps are applicable are identified. Gaps are given a label similar to the labels used in the Safety Factor reports. The labels have the form **Pickering PSR2 Gap COP-x.** These gaps will be assessed in the Global Assessment.

The associated Safety Factors are assigned with numbering consistent with the PSR2 Basis Document [10]:

1. Plant Design
2. Actual Condition of SSCs Important to Safety
3. Equipment Qualification (environmental and seismic)
4. Aging
5. Deterministic Safety Analysis
6. Probabilistic Safety Assessment
7. Hazard Analysis
8. Safety Performance
9. Use of Experience from Other Nuclear Power Plants and Research Findings
10. Organization, Management System and Safety Culture
11. Procedures
12. Human Factors
13. Emergency Planning
14. Radiological Impact on the Environment
15. Radiation Protection.

4.0 ASSESSMENT OF COP ACTIONS FOR APPICABILITY TO PSR2

IIP ID "E" actions are from the Environmental Assessment; "F" actions are from Life Cycle Management Plans (LCMP) or Condition Assessments (CA)[1], "G" actions arose from the Global Assessment, "I" actions originated in the Integrated Safety Review.

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
1	6	E01-01	IIP ID numbers 1-7 from Reference [13] originated as "E" actions from the Environmental Assessment and did not originate from the ISR. These actions are not within the scope of the PSR2 review.				
2		E01-01(a)					
3	7	E01-02					
4		E01-2(a)					
5	8	E02-01					
6		E02-01(a)					
7	1	E03-01					
8	9	F01	Develop a strategy to provide evidence that the Calandria Tube (CT) to Liquid Injection Shutdown System (LISS) nozzle gap will be maintained beyond 247k Equivalent Full Power Hours (EFPH) for all Pickering B units.	Complete	Actions were constrained by the shutdown date of 2020 assumed in the 2011 business plan. The strategy for CT - LISS nozzle gap preservation may apply beyond 2025, but has not been	This gap is addressed in the Safety Factor 4 report (Reference [14]) as **PSR2 Gap SF4-18.** For completeness, the specific wording of this gap is repeated in Section 4.1 of this report.	4

[1] Condition Assessments were referred to as Component Condition Assessments (CCAs) during the ISR.

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
					confirmed. This is therefore identified as a gap for Pickering PSR2. There is no implication for Pickering Units 1,4 since there are no LISS nozzles.		
9	10	F01-1	This is a log entry. OPG was requested to consider the proposed action that follows. Review the prediction model for CT/LISS Nozzle time to contact to identify over-conservatism.	Dispositioned	Entries 9, 10, 11, and 12 are all related to entry 8.	This is a log entry that expands upon F01. Refer to F01.	Not Applicable
10	11	F01-2	This is a log entry. OPG was requested to consider the proposed action that follows: Perform CT-LISS gap measurement for unit 7 during P1471.	Dispositioned	Entries 9, 10, 11, and 12 are all related to entry 8.	This is a log entry that expands upon F01. Refer to F01.	Not Applicable
11	12	F01-3	This is a log entry. OPG was requested to consider the proposed action that follows: Conduct a new assessment to estimate revised CT/LISS time to contact with reduced conservatism for all Pickering B units based on new installation information and latest Pressure Tube (PT) sag data.	Dispositioned	Entries 9, 10, 11, and 12 are all related to entry 8.	This is a log entry that expands upon F01. Refer to F01.	Not Applicable

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
12	13	F01-4	This is a log entry. OPG was asked to consider the proposed action that follows: Confirm whether CT/LISS nozzle contact can be precluded or not for Pickering B units prior to 247k EFPH.	Dispositioned	Entries 9, 10, 11, and 12 are all related to entry 8.	This is a log entry that expands upon F01. Refer to F01.	Not Applicable
13	14	F02	Develop Research and Development (R&D) justification for extending Fuel Channel design life to 247k EFPH and beyond in the areas of hydrogen ingress & fracture toughness, spacer mobility and integrity.	Complete	Actions were constrained by the shutdown date of 2020 assumed in the 2011 business plan. This assessment only addressed to 2025. This is therefore a gap for Pickering PSR2. This issue applies to Pickering Units 1,4 and 5-8. Note that OPG is continuing to provide the CNSC with evidence to support the extended operation of the fuel channels. The work is being conducted in a staged approach. (See, for example, Reference [35].)	This gap is addressed in the Safety Factor 4 report (Reference [14]) as **PSR2 Gap SF4-18.**	4

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
14		F02-1a	Provide written update on: (1) Evaluation of operations procedure changes at Pickering Nuclear Generating Station (PNGS) 5-8 to improve margins on Fracture Protection (FP) and Leak-Before-Break (LBB) assessments and (2) Status of installation of annulus gas system Dew-Point Rate of Rise (DPROR).	Closed to another action or process. (Reference [13])	This action was addressed under the Hold Point that is governed by Licence Condition Handbook (LCH) Section 16.3 (Reference [13]). The action was subsequently closed in Reference [9]. (1) OPG implemented procedure changes to improve margins. (2) The DPROR capability has been installed and commissioned on Pickering NGS Units 5-8. The issue is impacted by extended operation since the probabilistic LBB assessments that have been done must take into consideration the requirements for pressure tube life. This issue is also applicable to Pickering Units 1,4. Note that OPG is continuing to conduct work in this area in a staged	The probabilistic LBB assessments have not yet been fully completed for the entire extended operating period, as work is being performed to demonstrate fitness for service for the pressure tubes in a staged approach. **(<u>Pickering PSR2 Gap COP-1</u>)**	2

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
					approach. (See, for example, References [36] and [37].)		
15		F02-1b	Provide update on: (1) Development of probabilistic LBB and FP methodologies, (2) Schedule for LBB and FP assessments using improved models, methodologies and operating procedures (as applicable) (3) Rolled Joint Deuterium (RJD) ingress model improvements, (4) Rolled Joint (RJ) scrape sampling results.	Closed to another action or process. (Reference [13])	This action was addressed under the Hold Point that is governed by LCH Section 16.3 (Reference [13]). The action was subsequently closed in Reference [9]. Since COP action parts 1, 2, and 3 are complete for Pickering Units 5-8; since the same methodologies are used for Pickering Units 1,4, there is no impact on Pickering Units 1,4. With respect to COP action part 4, this request for specific information for Pickering Units 5-8 was addressed. Going forward, the periodic inspection program requires rolled joint scrapes at defined intervals for Pickering Units 1,4 and 5-8. This action is not impacted by extended operation.	No gap	Not Applicable

Actions F14-4.2, F14-5, and G04-02 from the Pickering Units 5-8 Continued Operations Plan are related to CSA N287.7 and CSA N291, and although complete, have not been updated for implications of the full extended operation for Pickering Units 1,4 and 5-8. This gap is addressed in the Safety Factor 4 report (Reference [14]) as **PSR2 Gap SF4-13.**	4
39	32	F14-5	Submit the Ageing Management Plan for N287.7 Concrete Containment Structures to the CNSC review and provide fitness for service to end of mission time.	Complete	This action was to provide the CNSC with specific information in response to an inquiry. This action is complete. This issue has not been addressed in the context of	This gap is already identified under IIP ID F14-4.2 (ID Number 38) and addressed in the Safety Factor 4 report (Reference [14]) as part of **PSR2 Gap SF4-13.**	4

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
					extended operation. This issue applies to Pickering Units 1,4 and 5-8. This is a gap for Pickering PSR2.		
40	4	G01-04	Demonstrate adequate safety margins to operate Pickering B units from an HTS ageing perspective to Jan 31, 2021.	Complete. In Reference [13], CNSC staff identify that the issue will be monitored up to the new target date of 2028 for end of commercial operations.	As discussed in COP (Reference [9]) Section 2.4: *In 2015, COP improvement action G01-04 was completed with the issuance of the 2015 strategy update to CNSC staff, which provided a progress report on Heat Transport System (HTS) Aging Safety Analysis and related activities, and an updated revision of the HTS Aging Management Strategy (HTS-AMS) for the period 2015-2020. The main focus of the 2015 revision of the HTS-AMS was the progression of the Safety Analyses to demonstrate continued safe operation of Pickering Units 5-8 until currently planned end-of-commercial operation. Updates on several experimental and research & development activities which are in*	This gap is addressed in the Safety Factor 4 report (Reference [14]) as **PSR2 Gap SF4-18.**	4, 5

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
					progress with the intention of demonstrating improved safety margins were also included. This assessment only addressed to 2020. This issue applies to Pickering Units 1,4 and 5-8. This is a gap for Pickering PSR2.		
41		G01-05	Develop an action plan to address the remaining generic deficiencies in the Two Unequal Fluids (TUF) code validation.	Closed to another action or process (Reference [13])	CNSC staff agreed that this action should be tracked within the Pickering regulatory program under Action Item (AI) # 2011 OPG-01, and Regulatory Management (RegM) Action Request (AR) 28137598-03. Therefore, this action is closed in the COP. Based on continued work and communications, the CNSC have subsequently closed Action Item 2011OPG-01 [30]. There is no impact on extended operation or on operation of Pickering Units 1,4.	No gap	Not Applicable

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
					There is no PSR2 gap.		
42		G01-06	Address regulatory concerns raised with the 28-element Boiling Length Average (BLA) Critical Heat Flux (CHF) Correlation analysis plan.	Closed to another action or process (Reference [13])	CNSC staff agreed that this action should be tracked within the Pickering regulatory program under AI 201113-2297 (Reference [13]). The CNSC have closed the associated action item AI 2012-OPG-3464 (N-CORR-00531-06063 [32]) but AI 201113-2297 related to Pickering 28 element fuel remains open (N-CORR-00531-05900 [33]]. The methodology and correlations are applicable to 28-element fuel so Pickering Units 1,4 and 5-8 are addressed. The analysis (Reference [16]) bounds both un-crept and fully crept pressure tubes. Therefore, the methodology and correlations are not affected by extended operation. However, AI 201113-2297 has not been closed by the	There are remaining issues from AI 201113-2297 follow-up related to providing a detailed assessment report of the uncertainty in the implementation and use of BLA CHF correlation for 28 element fuel. **(Pickering PSR2 Gap COP-14)**	5

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
					CNSC for Pickering NGS 28 element fuel. This is a gap for Pickering PSR2.		
43		G02-01	Track to completion Generic Action Item (GAI) 01G01 "Fuel Management and Surveillance Software Upgrade".	Closed to another action or process (Reference [13])	CNSC staff agreed that this action can be tracked within the Sustainable Operations Plan (SOP), under SCA04-08. CNSC provided closure of GAI 01G01, "Fuel Management and Surveillance Software Upgrade" and opened AI 2012-OPG-3465 to track associated actions. Per N-CORR-00531-07323 (Reference [17]), OPG addressed CNSC staff requests for both Pickering Units 1,4 and 5-8 and requested closure of AI 2012-OPG-3465. The issue has been closed (Reference [18]), however follow-up action has been identified per AI 2016-OPG-8250. OPG has provided a response to this Action Item (N-CORR-00531-18204 [31])	There are remaining issues from Generic Action Item (GAI) 01G01 "Fuel Management and Surveillance Software Upgrade" (AI 2016-OPG-8250). **(Pickering PSR2 Gap COP-15)**	5

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
					indicating additional information is planned by May 2017. This issue applies to Pickering Units 1,4 and Units 5-8. There is a gap for Pickering PSR2.		
44		G02-02	Track to completion GAI 95G04 "Positive Void Reactivity Uncertainty - Treatment in Large Loss of Coolant Accident (LOCA) Analysis".	Closed to another action or process (Reference [13])	CNSC staff agreed that this action be tracked within the SOP, under SCA04-09. CNSC staff subsequently closed SCA04-09 indicating the issue was dealt with appropriately under SOP SCA04-07 [13]. SOP SCA-04-07 derives from COP item I09 (ID number 68) which is also considered in this reassessment. There is no impact on extended operation or on operation of Pickering Units 1,4. There is no PSR2 gap.	No gap	Not Applicable
45		G02-03	Track to completion GAI 99G02 "Replacement of Reactor Physics Computer Codes used in Safety	Closed to another action or process	CNSC staff agreed that this action be tracked within	No gap	Not Applicable

ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
			Analysis of CANDU Reactors".	(Reference [13])	the SOP, under SCA04-10. CNSC staff subsequently closed SCA04-10 indicating the issue was dealt with appropriately under SOP SCA04-07 [13]. SOP SCA-04-07 derives from COP item I09 (ID number 68) which is also considered in this reassessment. There is no impact on extended operation or on operation of Pickering Units 1,4. There is no PSR2 gap.		
46		G02-04	Track to completion GAI 00G01 "Channel Voiding during a LOCA".	Closed to another action or process (Reference [13])	CNSC staff agreed that this action be tracked within the SOP, under SCA04-11. This issue was tracked as Action Item 2012OPG-3317. CNSC have closed this action (N-CORR-00531-06689 [34]). There is no impact on extended operation or on operation of Pickering Units 1,4.	No gap	Not Applicable

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
					There is no PSR2 gap.		
47		G04-01	Develop and issue a high-level generic leakage rate test requirements document to address the clauses of CSA N287.7-08 relevant to leakage rate testing for the Pickering B Reactor Buildings, entitled Pickering B Reactor Building In-Service Leakage Rate Test Requirements in Accordance with CSA N287.7-08.	Closed to another action or process (Reference [13])	This action was closed to Action G04-02 in the COP (ID Number 48) (Reference [13]) which is also considered in this reassessment. There is no impact on extended operation or on operation of Pickering Units 1,4. There is no PSR2 gap.	No gap	Not Applicable
48	33	G04-02	Revise NK30-PIP-03643.2-00001, Reactor Building Periodic Inspection Program, to comply with CSA Standard N287.7-08 and include the Embedded Parts List. Submit NK30-PIP-03643.2-00001 R003 to CNSC for acceptance. Revise N-PROC-MA-0066 to reference the Leakage Rate Test document.	Complete	Revise NK30-PIP-03643.2-00001, Reactor Building Periodic Inspection Program, to comply with CSA Standard N287.7-08 to address extended operation. This issue has not been addressed in the context of extended operation. This issue applies to Pickering Units 1,4 and 5-8. This is a gap for Pickering PSR2.	This gap is already identified under IIP ID F14-4.2 (ID Number 38) and is addressed in the Safety Factor 4 report (Reference [14]) as part of **PSR2 Gap SF4-13.**	4

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
49		G04-03	Since a Vacuum Building Outage (VBO) will not be completed in 2020, document the licensing/technical basis for maintaining a fully serviceable containment boundary for the 2-3 years during which defueling and dewatering activities will be underway on the Pickering Units.	Closed to another action or process (Reference [13])	Action G04-03 in the COP was transferred to SOP action SCA04-04. (This was formerly identified as SOP action SCA06-07). (Reference [13]). OPG proposed to close this to the Stabilization Activity Plan (SAP) (Reference [13]). The issue must be reconsidered in the context of extended operation. Pickering Units 1,4 share the Vacuum Building with Pickering Units 5-8. This is a gap for Pickering PSR2.	Reassessment of the VBO schedule and basis for maintaining a fully serviceable containment boundary has not been completed for extended operations and until negative pressure containment can be demonstrated to no longer be required. **(Pickering PSR2 gap COP-16)**	5
50	34	G05-01	Issue the Pickering B, Priority 2 Safe Operating Envelope (SOE) systems documentation.	Complete	This action was to issue Priority 2 SOE systems documentation. This action is complete [13]. There is no impact on extended operation. This work has also been completed for Pickering	No gap	Not Applicable

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
					Units 1,4 (Reference [40]). There is no PSR2 gap.		
51	35	G05-02	2009 Global Assessment: The Global Assessment team recommends that OPG management review the results of the deterministic safety analysis to confirm sufficient defence in depth, production reliability and incorporation of conservative decision making and operating experience have been appropriately incorporated into the project scope. Disposition: The OPG Benefit Cost Analysis (BCA) process had been previously reviewed and accepted by the CNSC (Reference CD# NK30-CORR-00531-04417). If OPG had decided to refurbish, OPG would have deterministically reviewed the project scope to confirm sufficient Defence in Depth, operating experience, production reliability, and economic viability had been appropriately integrated into the project. However, given the decision was not to refurbish the Pickering B units, there is no benefit to reviewing this issue	Complete	There is no impact on extended operation or on operation of Pickering Units 1,4. There is no PSR2 gap. Note: Global Assessment under PSR2 is currently in progress.	No gap	Not Applicable

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
			further.				
52	36	G06-01	Demonstrate fire code compliance with CSA N293- 07 and Licence Condition 6.3.	Complete	This issue is not impacted by extended operation. Code Compliance review (Reference [19]) was also completed for Pickering A. There is no PSR2 gap. Note: The modern version of this CSA Standard (CSA N293-12) is in the current PSR2 assessment basis.	No gap	Not Applicable
53	37	G08-01	Complete the installation of the Passive Autocatalytic Recombiners (PARs) in all Pickering B units.	Complete	PARS installation is complete on all Pickering Units. This issue is not impacted by extended operation. There is no PSR2 gap.	No gap	Not Applicable
54	38	G09-01	Complete the installation and place in-service the upgraded seismic monitoring system.	Complete	The new seismic monitoring system was installed, commissioned, and placed in service as documented in P-REP-61150-00002 (Reference [20]). The seismic monitoring system upgrade addressed the entire	No gap	Not Applicable

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
					Pickering station so there is no gap for Pickering Units 1,4. This issue is not impacted by extended operation. There is no PSR2 gap.		
55	39	G10-01	Complete Level 1 Pickering B Probabilistic Risk Assessment (PRA) to demonstrate S-294 licence compliance.	Complete	Level 1 PRA is complete for Pickering Units 5-8 (Reference [38]) and Units 1,4 (Reference [39]). This issue is not impacted by extended operation. There is no PSR2 gap. Note: CNSC S-294 has been superseded by CNSC REGDOC-2.4.2. REGDOC-2.4.2 is in the current PSR2 assessment basis.	No gap	Not Applicable
56	40	G11-01	Perform Level 2 Pickering B PRA in Accordance with S-294 and Pickering B Pickering Reactor Operating Licence (PROL) Condition 3.12.	Complete	Level 2 PRA is complete for Pickering Units 5-8 (Reference [38]) and Units 1,4 (Reference [39]). This issue is not impacted by extended operation.	No gap	Not Applicable

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
					There is no PSR2 gap. Note: CNSC S-294 has been superseded by CNSC REGDOC-2.4.2. REGDOC-2.4.2 is in the current PSR2 assessment basis.		
57	41	I01	Document the level of compliance of Pickering plant structures supporting the operation of Pickering B reactors with CSA N289.3-M81 "Design Procedures for Seismic Qualification of CANDU Nuclear Power Plants", Clause 4.7.1 to 4.7.3. Perform a review of the relevant seismic analysis reports regarding seismic overturning and sliding stability and if seismic reports are not available, perform required calculations to demonstrate compliance. Document the level of compliance in formal correspondence and/or in engineering documents.	Complete	This issue is not impacted by extended operation. Reference [21] was prepared to document overturning and sliding safety factors for the PNGS-B Reactor Building and other structures. The report determined that the seismic overturning and sliding safety factors for these structures exceeded 1.25, thereby exceeding the requirements of CSA N289.3- M81, Clauses 4.7.1 - 4.7.3. The calculation of the safety factor of 1.25 against overturning is not required for Pickering since the structures are built on embedded piles anchored in solid rock. Therefore, overturning or toppling due	No gap	Not Applicable

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
					to earthquake and other loading is not a concern. This conclusion is applicable to all Pickering units given the similarity of the designs. There is no PSR2 gap.		
58	42	I02	Document the level of compliance of Pickering plant structures supporting the operation of Pickering B reactors with CSA N289.3-M81, "Design Procedures for Seismic Qualification of CANDU Nuclear Power Plants", Clause 5.13.2. Review the relevant seismic analysis reports regarding the minimum number of cycles used for seismic fatigue analysis and document the level of compliance by revising the OPG Design Guide, DG-30-68000-2, "Pickering G.S. 'B' Seismic Qualification of Safety Related Systems", (Vendor R02, OPG R00), December 1979, Section 6.4.	Complete	This IIP action was closed based on the number of cycles used in the seismic analysis reports. This issue must be reconsidered in the context of extended operation. This issue also applies to Pickering Units 1,4. This is a gap for Pickering PSR2.	A review that considers the minimum number of cycles used for seismic fatigue analysis has not been completed for the level of compliance of Pickering NGS plant structures supporting the operation of Pickering reactors with CSA N289.3-M81, "Design Procedures for Seismic Qualification of CANDU Nuclear Power Plants", Clause 5.13.2 in the context of extended operations. **(Pickering PSR2 gap COP-17)**	1

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
59	43	I03	Complete the Pickering B PRA based seismic margin assessment, as per Section 3.12 of the PNGS B Reactor Power Operating Licence and document compliance with regulatory document S-294, "Probabilistic Safety Assessments for NPP".	Complete	This issue is not impacted by extended operation. The Pickering NGS-A PRA-Based Seismic Margin Assessment is complete (Reference [22]). There is no PSR2 gap.	No gap	Not Applicable
60	44	I03-1	Provide evidence that the existing Pickering B Standby Generator and Emergency Power Generator (EPG) Fuel Oil storage tank systems comply with the National Fire Code of Canada (NFCC).	Complete	This issue is not impacted by extended operation. This action has been completed for Pickering Units 5-8. Evidence that a similar demonstration has been done for Pickering Units 1,4 with respect to the Standby Generator fuel tanks was not found. This is a gap for Pickering PSR2. Note: The modern version of the NFCC (NFCC-2010) is included in the current PSR2 assessment basis.	An assessment that shows that Standby Generator fuel tanks supporting units 1,4 comply with NFCC could not be found. **(Pickering PSR2 Gap COP-18)**	1
61	45	I04	Review standards ANSI/ASME N509-1980 and N510-1980 for Filtered Air Discharge System (FADS) and Non-SOE air	Complete	This issue is not impacted by extended operation.	A review of Pickering Units 1,4 Non-SOE air cleaning systems against ANSI/ASME N509-1980 and	1

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
			cleaning systems and document the level of compliance and any requirements for further action.		FADS is applicable to Pickering Units 1,4 and 5-8 (Reference [41]) so the basis of closure for Pickering Units 5-8 is also applicable to Pickering Units 1,4. For the Non-SOE air cleaning systems, a review of ANSI/ASME N509-1980 and N510-1980 for Pickering Units 1,4 has not been completed. This is a PSR2 gap.	N510-1980 has not been completed. **(Pickering PSR2 Gap COP-19)**	
62	46	I04-1	Resolution of gap 643 is being managed under project 10-26003, Fire Safety Assessment (FSA) Upgrade Project and correspondence with CNSC on licence amendment, N-CORR-00531-05297. OPG recommends tracking the Fire Protection 2007 Code Update via correspondence following aforementioned letter and associated project. The scope of project 10-26003, FSA Upgrade Project and correspondence with CNSC on the licence amendment, N-CORR-00531-05297; address the discrepancy, effectively closing the gap. This gap will be tracked through correspondences	Complete	This work was completed for Pickering 5-8. This issue is not impacted by extended operation. Fire Hazards Assessment (Reference [23]), Fire Safe Shutdown Assessment (Reference [24]), and Code Compliance review (Reference [19]), were also completed for Pickering A so there is no PSR2 gap.	No gap	Not Applicable

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
			associated with N-CORR- 00531-05297 and project 10-26003.				
63		I05	Complete the FSA Upgrade Project in order to comply with CSA N-293-07. This action will be addressed under G06-01.	Closed to another action or process (Reference [13])	This action was closed to Action IIP ID G06-01 (ID Number 52) in the COP (Reference [13]). This issue is not impacted by extended operation. Refer to I04-1 (ID Number 62) for impact on Pickering Units 1,4. There is no PSR2 gap.	No gap	Not Applicable
64	47	I06	Revise PNGS-B Shutdown System SDS1 Design Requirements document, NK30-DR-63720-10001 R0, and SDS2 Design Requirements document, NK30-DR-63730- 10002 R0, (and associated sub-component design requirements documents), as per Document Change Requests (DCRs) 114575, 114576, 114577 in order to document level of compliance with CSA N290.1-80.	Complete	This issue is not impacted by extended operation. A review against CSA N290.1 is done of both Pickering Units 1,4 and Pickering Units 5-8 as part of PSR2. These are no PSR2 gaps.	No gap	Not Applicable
65		I06-1	Provide evidence that ISR Gaps 1-307 to 1-319 and I-358 are closed. CNSC staff disagrees that Gaps 1-307 to 1-319 and 1-	Closed to another action or process (Reference [13])	The action was closed to IIP ID I06 (ID Number 64) which was completed	No gap	Not Applicable

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
			358 be closed. The disposition of Gaps 1-308, 1-310, 1-312, 1-314, 1-319, and 1-358 are to be transferred by OPG to Pickering B COP, and be coded as this new Action I06-1, with a Target Completion Date (TCD) of October 1, 2012; similar to that of Action I06.		(Reference [13]). This issue is not impacted by extended operation. There is no impact on Pickering Units 1,4. There is no PSR2 gap.		
66	48	I07	Revise Emergency Coolant Injection System (ECIS) Design Requirements NK30-DR-33350-10004 and ECIS Design Manual NK30-33350-00002 as per DCR 114573 and Operational Safety Requirements for ECIS NK30-OSR-08131.02-00001 as per DCR 19510, in order to document compliance with Atomic Energy Control Board Regulatory Guide R-9.	Complete	This issue is not impacted by extended operation. CSA N290.2-11 replaces Regulatory Document, R-9, and is largely based on it. A review against CSA N290.2 is done of both Pickering Units 1,4 and Pickering Units 5-8 as part of PSR2. These is no PSR2 gap.	No gap	Not Applicable
67	49	I08	Revise Pickering-B Design Manual for Emergency Power System (EPS) Generators Fuel Oil System NK30-DM-54860-00001, and Pickering-B Design Manual for Standby Generators Fuel Oil System NK30- DM-54660-00001 (as per DCR 114562), in order to reflect compliance with NFCC 2005.	Complete	This issue is not impacted by extended operation. There is no impact on Pickering Units 1,4. There is no PSR2 gap.	No gap	Not Applicable

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
68		I09	Implement the results of COG Joint Project JP-4367 to resolve the PNGSB Legacy analysis codes and methods issues with the analysis for Large Break Loss of Coolant Accident (LBLOCA).	Closed to another action or process (Reference [13])	This action was transferred to the SOP and renamed SCA04-07. This action will continue to be tracked under the Pickering regulatory program (Reference [13]). The licensing basis of existing CANDU reactors for the LBLOCA scenario will continue to be based on conservative safety analysis for which acceptance criteria are established. Since three LBLOCA CANDU Safety Issues (CSIs) applicable to Pickering NGS remain in the high risk category (Category 3) and require further assessment in order to re-classify into a lower risk category and cover operation past 2020, a gap exists for Pickering PSR2. This issue applies to Pickering Units 1,4 and 5-8. This is a gap for Pickering PSR2.	Three LBLOCA CANDU Safety Issues that are applicable to NGS remain in Category 3 and have not been fully reassessed in order to re-classify into a lower risk category and cover operation past 2020. **(Pickering PSR2 Gap COP-20)**	5

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
69		I10	Demonstrate compliance of the PNGS B Safety Report relative to RD-310 "Safety Analysis for NPP" by completing gap assessments of the Safety Report versus RD-310 requirements including code validation as per AI 2010OPG-05. Prepare plans to address identified gaps. Execute the plans as part of the migration to RD-310 compliance.	Closed to another action or process (Reference [13])	This action was closed in the COP, as it was transferred to the SOP and renamed SCA04-13. OPG completed the gap assessments, and CNSC staff accepted the OPG submission (Reference [13]). This action has not been considered in the context of extended operation. This is a gap for Pickering PSR2. Note: CNSC RD-310 has been superseded by CNSC REGDOC-2.4.1. REGDOC-2.4.1 is in the current PSR2 assessment basis.	The updates to the Safety Reports are being conducted in accordance with the REGDOC-2.4.1 Implementation Plan (REGDOC-2.4.1 superseded CNSC RD-310). This plan did not consider operation beyond 2020, for Pickering Units 1,4 and Units 5-8. **(Pickering PSR2 Gap COP-21)**	5
70		I10-01	As part of OPG's plan for RD-310 implementation at Pickering site, OPG plans to complete limited upgrades to the Pickering B Safety Report. These upgrades will include addressing the current gap in covering Common Mode Events. This action will close ISR Gap 5-389 which identified that with respect to	Closed to another action or process (Reference [13])	This action was transferred to the SOP in 2013 and re-named SCA04-14. The criteria for prioritization of the Safety Report upgrades included remaining operating life. This issue has not been addressed in the context of	Implications described under IIP ID I10 (immediately above) are applicable to this action. The same gap applies. **(Pickering PSR2 gap COP-21)**	5

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
			Safety Assessments (Analysis) the set of Postulated Internal Events (PIE) should include events such as fires, explosions, turbine missile impacts and floods of internal origin which could affect the safety of the reactor and cause failure of some of the safety system equipment which provides protection for that initiating event.		extended operation. This issue applies to Pickering Units 1,4 and Units 5-8. This is a gap for Pickering PSR2.		
71		I11	Complete the Pickering B PRA update (Level 2 PRA) in Accordance with S-294 and Pickering B PROL Condition 3.12.	Closed to another action or process (Reference [13])	This action is closed to another COP action G11-01 (ID Number 56) "Perform Level 2 Probabilistic Risk Assessment (PRA) in Accordance with S-294 and Pickering B PROL Condition 3.12". The Pickering Units 5-8 Level 2 PRA is complete. There is no impact of extended operation. The Pickering Units 1,4 Level 2 PRA is complete (Reference [39]). There is no PSR2 gap. Note: CNSC S-294 has	No gap	Not Applicable

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability

			the CNSC in accordance with Pickering B PROL 08.20/2013 Licence Condition 1.2.		major components to achieve extended operations to 2024. This issue has not been addressed in the context of extended operation. The issue has not been considered for Pickering Units 1,4. Therefore, this is a gap for Pickering PSR2.		
95	70	I15-7b	With respect to the calandria and internal structures, provide the results of the COG Joint Project #4220 regarding the guide tube springs. The results should provide evidence that guide tube springs will remain fit for service for the mission life.	Complete	An interim LCMP update for major components is documented in P-CORR-01060-0587604 R000 (Reference [15]), which describes life cycle management strategies for major components to achieve extended operations to 2024. This issue has not been addressed in the context of extended operation. This issue applies to Pickering Units 1,4 and 5-8. Therefore, this is a gap for Pickering PSR2.	A review for the full period of extended operation has not been completed of evidence that calandria and internal structure guide tube springs for Pickering Units 1,4 and 5-8 will remain fit for service. **(Pickering PSR2 gap COP-26)**	2

COP Action #		IIP ID or Code	Summary of Item	Status	Impacted by Operation Past 2020 to 2028 or Implications for Pickering Units 1,4?	Implications for PSR2	Safety Factor Applicability
ID number from Ref. [13]	ID number from App A of COP (Ref. [8])			Based on App A of COP (Ref. [8]) unless noted otherwise)			
					Note: OPG is in the process of updating its LCMPs and condition assessments in support of extended operation.		

4.1 PICKERING NGS PSR2 SAFETY FACTOR 4

In Pickering NGS PSR2 Safety Factor 4 report [14], COP actions were evaluated for applicability for PSR2. Two gaps were identified. For completeness, the text of the related PSR2 gaps is repeated below.

Gap SF4-13

The PSR2 gap is as follows:

Actions #31, #32, and #33 from the Pickering Units 5-8 Continued Operations Plan are related to N287.7 and although complete, need to be re-assessed for Pickering operation past 2020 **(Pickering PSR2 Gap SF4-13)**. (IIP Action #31 involved submission of Periodic Inspection Plans and Life Cycle Management Plans for a number of safety-significant civil structures. IIP Action #32 involved submission of Aging Management Plans for concrete containment structures to the CNSC for acceptance. IIP Action #33 involved revising the Reactor Building Periodic Inspection Plan and submitting to the CNSC for acceptance).

Gap SF4-18

The PSR2 gap is as follows:

Review of the Pickering Units 5-8 Continued Operations Plan [8] identified the following closed gaps from the Pickering B ISR that will need to be revisited in the context of continued operation past 2020 for PSR2 Safety Factor 4 (**Pickering PSR2 Gap SF4-18**):

ID number from App A of COP (Ref. [8])	IIP ID [1] or Code	Summary of Item *
4	G01-04	Demonstrate adequate safety margins to operate Pickering B units from a Heat Transport System aging perspective to Jan 31, 2021. The 2015 strategy update to CNSC staff provided a progress report on HTS Aging Safety Analysis and related activities, and an updated revision of the HTS Aging Management Strategy for the period 2015-2020. This needs to be expanded to cover operation past 2020 for Pickering Units 1,4 and Units 5-8. Therefore, this is a gap for Pickering PSR2.
9, 10, 11, 12, 13	F01 (including F01-1, F01-2, F01-3, F01-4)	Develop a strategy to provide evidence that the Calandria Tube (CT) - Liquid Injection Shutdown System (LISS) nozzle gap will be maintained beyond 240,000 Effective Full Power Hours (EFPH) for all Pickering B units. The strategy for CT - LISS nozzle gap preservation may apply beyond 2025, but this needs to be confirmed. Therefore, this is a gap for Pickering PSR2.
14	F02	Develop R&D justification for extending Fuel Channel design life beyond 240,000 EFPH in the areas of hydrogen ingress, fracture toughness, spacer mobility and integrity. Actions were constrained by the shutdown date of 2020 assumed in the 2011 business plan. This needs to be expanded to cover operation past 2020 and is therefore a gap for Pickering PSR2.

ID number from App A of COP (Ref. [8])	IIP ID [1] or Code	Summary of Item *
		Note: An interim LCMP update for major components is documented in P-CORR-01060-0587604 R000 [15], which describes life cycle management strategies for major components to achieve extended operations to 2024. Strategies in this document may apply beyond 2024, but this needs to be confirmed as part of the resolution of this COP-related PSR2 gap.
19	F13	Update the NOP analysis for Pickering B. Actions were constrained by the shutdown date of 2020 assumed in the 2011 business plan. This is primarily relevant to Safety Factor 5 but is also of relevance to Safety Factor 4. This needs to be expanded to cover operation past 2020 for Pickering Units 1,4 and Units 5-8. Therefore, this is a gap for Pickering PSR2.
21	F14-1a	For the Feeder LCMPs, clarify the impact of fuel channel axial elongation during operation beyond the fuel channel assumed design life of 210,000 EFPH on feeder stress analysis and acceptable feeder thickness. This was only addressed to 2025. This needs to be expanded to cover operation to 2028. Therefore, this is a gap for Pickering PSR2. Note: An interim LCMP update for major components is documented in P-CORR-01060-0587604 R000 [15], which describes life cycle management strategies for major components to achieve extended operations to 2024. Strategies in this document may apply beyond 2024, but this needs to be confirmed as part of the resolution of this COP-related PSR2 gap.
30	F14-4.1	Include the periodic inspection programs and LCMPs for the secondary side pressure retaining components and submit them for CNSC review. Although the action to submit PIPs and LCMPs for the secondary side pressure retaining components is complete, these documents will need to be extended to cover operation past 2020 for Pickering Units 1,4 and Units 5-8. Therefore, this is a gap for Pickering PSR2.
52	I15-1a	Perform Time Limiting Aging Analysis (TLAAs) and include such TLAAs in the LCMPs and in the CAs. OPG to provide commitment that TLAAs necessary to determine the actual conditions of components will be completed. Although the action is complete, this will need to be updated to cover operation past 2020 for Pickering Units 1,4 and Units 5-8. Therefore, this is a gap for Pickering PSR2.
69	I15-7a	Include relevant information from COG JP 4271 Calandria and internals. Fitness for Life Extension Guidelines in N-PLAN-01060-10003 “Reactor Components and Structures Life Cycle Management Plan (LCMP)” and submit the LCMP to the CNSC in accordance with Pickering B PROL 08.20/2013 LC 1.2. Although the action is complete, this will need to be updated to cover operation past 2020 for Pickering Units 1,4 and Units 5-8. Therefore, this is a gap for Pickering PSR2. Note: An interim LCMP update for major components is documented in P-

ID number from App A of COP (Ref. [8])	IIP ID [1] or Code	Summary of Item *
		CORR-01060-0587604 R000 (Reference [15]) which describes life cycle management strategies for major components to achieve extended operations to 2024. Strategies in this document may apply beyond 2024, but this needs to be confirmed as part of the resolution of this COP-related PSR2 gap.
Appendix C, Item 5	F11	Update the Pickering B HTS aging model. This action is complete but needs to be reviewed to assess impact of operation past 2020 for Pickering Units 1,4 and Units 5-8. Therefore, this is a gap for Pickering PSR2.
Appendix C, Item 6	F12	Update the Pickering B HTS aging management strategy. This action is complete but needs to be reviewed to assess impact of operation past 2020 for Pickering Units 1,4 and Units 5-8. Therefore, this is a gap for Pickering PSR2.

* Closed Pickering Units 5-8 COP actions were reviewed to determine whether they need to be reassessed (PSR2 gaps identified) to address operation past 2020. Where applicable, equivalent Pickering Units 1,4 PSR2 gaps are also identified where reassessment will be required for operation past 2020.

EXECUTIVE SUMMARY

Fukushima Action Items (FAIs) are considered for applicability to Pickering Periodic Safety Review (PSR2) in this report. The PSR2 Basis Document, Section 3.2.1 (Reference [1]) states that Fukushima actions will be assessed to determine if there are any impacts associated with operation past 2020. Also, in Reference [2], the Canadian Nuclear Safety Commission (CNSC) recommended that OPG consider the FAIs that were closed on the basis that Pickering NGS units were to shut down in 2020. The basis of FAI closure has been assessed to determine if it is affected by extending the operation beyond 2020.

There were no Pickering PSR2 gaps identified in this report.

TABLE OF CONTENTS

LIST OF TABLES

1.0 INTRODUCTION

Fukushima Action Items (FAIs) are considered for applicability to Pickering Periodic Safety Review (PSR2) in this report. The PSR2 Basis Document, Section 3.2.1 (Reference [1]) states that Fukushima actions will be assessed to determine if there are any impacts associated with operation past 2020. This is consistent with the CNSC recommendation in Reference [2] for OPG to consider the FAIs that were closed on the basis that Pickering NGS units were to shut down in 2020. The CNSC recommendation was to determine if the basis of closure is affected by the potential to operate Pickering to 2028 rather than 2020.

The FAIs were originally identified in Reference [3]. The status of all FAIs for OPG facilities was summarized in OPG's Fukushima Action Item Status Report, N-REP-03600-10003 [4]. As noted in Reference [4], OPG has completed, and the CNSC has closed all FAIs assigned to OPG. The assessment of the impact of extended operation on all FAIs assigned to OPG that are applicable to Pickering NGS is provided in Table 1 in Section 4.0.

2.0 SCOPE OF REVIEW

This report considers all FAIs that were listed in Reference [3] and the follow up actions that have been created to monitor progress related to specific issues. The assessment considers Units 1,4 and Units 5-8. Common systems (Unit 0) are included in the Unit assessments as applicable.

3.0 METHODOLOGY

The FAIs listed in Table 1 are taken directly from Reference [3]. The dates listed with each FAI are those identified in Reference [3] when the FAIs were originally developed. The impact of extended operation was considered for Units 1,4 and for Units 5-8. In cases where Units 1,4 and Units 5-8 have the same implications, these discussions are combined.

4.0 ASSESSMENT FINDINGS

The assessment is documented in Table 1.

Table 1: Impact of Extended Operation on FAIs – Assessment Results

#	Fukushima Action Item [3]	Assessment of Impact of Operation Beyond 2020		Results
		Pickering Units 1,4	Pickering Units 5-8	
1	FAI 1.1.1[1] An updated evaluation of the capability of bleed condenser / degasser condenser relief valves providing additional evidence that the valves have sufficient capacity. December 2012.[2]	As outlined in Reference [4], an assessment was performed that demonstrated that the installed Relief Valves on the Bleed Condenser provide sufficient relief capacity such that pressure boundary failure due to overpressure will not occur. FAI 1.1.1 is closed. This conclusion is not impacted by extended operation.		No gap
2	FAI 1.1.2 If required, a plan and schedule either for confirmatory testing of installation or provision for additional relief capacity. December 2012.	No further action is required based on results of FAI 1.1.1. [4] FAI 1.1.2 is closed. This conclusion is not impacted by extended operation.		No gap

[1] The FAI numbering shown here is from Reference [4], which reflects the CNSC FAI numbering that was adopted following the initial issuance of the FAIs in Reference [3]. For communications that followed after Reference [3], the CNSC (and industry) adopted a standard three digit FAI numbering system which affected some FAI numbers (e.g., FAI 1.1 became FAI 1.1.1). Affected FAI numbers (changes from Reference [3] to Reference [4]) are FAI 1.1 (1.1.1), 1.4 (1.4.1), 1.5 (1.5.1), 1.7 (1.7.1), 1.8 (1.8.1), 1.9 (1.9.1), 1.11 (1.11.1), 2.2 (2.2.1), 4.2 (4.2.1), 5.3 (5.3.1) and 5.4 (5.4.1).

[2] Dates shown are the due dates identified in Reference [3] when the FAIs were originally assigned.

#	Fukushima Action Item [3]	Assessment of Impact of Operation Beyond 2020		Results
		Pickering Units 1,4	Pickering Units 5-8	
3	FAI 1.2.1 An assessment of the capability of shield tank/calandria vault relief. December 2013.	N/A [3] This action does not apply to Pickering Units 1,4 because there is no shield tank in the design of these units.	As outlined in Reference [4], a review of the Calandria Vault (CV) structural integrity has been completed which confirms the adequacy of relief capability. FAI 1.2.1 is closed. This conclusion is not impacted by extended operation.	No gap
4	FAI 1.2.2 If relief capacity is inadequate, an assessment of the benefit available from adequate relief capacity and the practicability of providing additional relief. December 2013.	N/A [3] This action does not apply to Pickering Units 1,4 because there is no shield tank in the design of these units.	As outlined in Reference [4], analyses show that there is sufficient release through the CV plug to prevent over-pressurization of the CV. No further action is required. Refer to FAI 1.2.1 for further information. FAI 1.2.2 is closed. This conclusion is not impacted by extended operation.	No gap
5	FAI 1.2.3 If additional relief is beneficial and practicable, a plan and schedule for provision of additional relief. December 2013.	N/A [3] This action does not apply to Pickering Units 1,4 because there is no shield tank in the design of these units.	As outlined in Reference [4], analyses show that there is sufficient release through the CV plug to prevent over-pressurization of the CV. Refer to FAI 1.2.1 for further information. FAI 1.2.3 is closed. This conclusion is not impacted by extended operation.	No gap

#	Fukushima Action Item [3]	Assessment of Impact of Operation Beyond 2020		Results
		Pickering Units 1,4	Pickering Units 5-8	
6	FAI 1.3.1 Assessments of adequacy of the existing means to protect containment integrity and prevent uncontrolled release in beyond design basis accidents including severe accidents. December 2015.	As outlined in Reference [4], the FAI was closed based on the Level 2 Probabilistic Risk Assessment[3] (PRA) results, and considering overall containment performance under Beyond Design Basis Accident (BDBA) conditions. This included an assessment of the effectiveness of the Phase 1 and Phase 2 Emergency Mitigating Equipment (EME) mitigation of multi-unit "Total Loss of Heat Sink" events. The Phase 1 EME is currently available for service, and addresses the majority of postulated BDBAs. Phase 2 EME is a planned enhancement. FAI 1.3.1 is closed. This conclusion is not impacted by extended operation (Reference [5]). See also further discussion under FAI 1.3.2.		No gap

[3] Note that Probabilistic Risk Assessment is now referred to as Probabilistic Safety Assessment.

#	Fukushima Action Item [3]	Assessment of Impact of Operation Beyond 2020		Results
		Pickering Units 1,4	**Pickering Units 5-8**	
7	FAI 1.3.2 Where the existing means to protect containment integrity and prevent uncontrolled releases of radioactive products in beyond design basis accidents including severe accidents are found inadequate, a plan and schedule for design enhancements to control long term radiological releases and, to the extent practicable, unfiltered releases. December 2015.	As outlined in Reference [4], there are common elements to this activity for Pickering Units 1,4 and Pickering Units 5-8, because of the shared containment envelope. As discussed under FAI 1.3.1, and further reviewed in Reference [6], OPG has completed analyses for Pickering which outline the extent to which containment integrity may be challenged under BDBA conditions. OPG has assessed various options which can be implemented to enhance containment performance under extreme conditions. It has been determined that the existing and planned equipment upgrades (to address Fukushima related issues) are sufficient to address containment integrity challenges under BDBA conditions, and no further modifications are warranted. FAI 1.3.2 is closed. The original FAI 1.3.1/1.3.2 assessment for Pickering is summarized in P-REP-09013-00002, "Pickering NGS - Beyond Design Basis Containment Integrity" [6]. This evaluation supported the closure of FAI 1.3.2 for Pickering NGS. FAI 1.3.1/1.3.2 was reassessed in Reference [5] taking into consideration the extended operation of Pickering NGS. The updated assessment of containment integrity in BDBAs at Pickering NGS concluded that the initial response to these FAIs remains valid for the extension of commercial operation. This was based on a number of considerations outlined in References [5] and [6], including the Beyond Design Basis Nuclear Safety Principles adopted by the Chief Nuclear Engineers of the Canadian Nuclear Utilities which focus on prevention, the defence-in-depth capability of the design features of the plant and the additional EME provisions, consideration of safety goals and benefits, and additional risk improvement initiatives already underway at Pickering NGS [9].		No gap

#	Fukushima Action Item [3]	Assessment of Impact of Operation Beyond 2020		Results
		Pickering Units 1,4	Pickering Units 5-8	
8	FAI 1.4.1 A plan and schedule for the installation of Passive Autocatalytic Recombiners (PARs) as quickly as possible. December 2012.	As indicated in Reference [3] this FAI was closed. PARs have been installed [4]. Programs are in place to ensure continued operation of the PARs [10]. This conclusion is not impacted by extended operation.		No gap
9	FAI 1.5.1 An evaluation of the potential for hydrogen generation in the Irradiated Fuel Bay (IFB) area and the need for hydrogen mitigation. December 2013.	As outlined in Reference [4], OPG has completed an assessment for the IFBs at Pickering NGS under FAI 1.6.1. This assessment demonstrates that there is high confidence that the IFBs at Pickering NGS will remain filled under an extended loss of IFB cooling event, crediting existing IFB coolant make-up strategies. Therefore, hydrogen production, aside from the normal production from radiolysis, will not occur and hydrogen mitigation in the IFBs is not required. FAI 1.5.1 is closed. This conclusion is not impacted by extended operation.		No gap
10	FAI 1.6.1 An evaluation of the structural response of the IFB structure to temperatures in excess of the design temperature, including an assessment of the maximum credible leak rate following any predicted structural damage. December 2013.	As outlined in Reference [4], OPG has completed an assessment for Pickering NGS IFBs. This assessment demonstrated that in the event of a loss of IFB cooling, some IFB leakage may occur as temperatures approach boiling. However, the leakage make-up requirements are well within the capability of portable EME pumps. The assessment showed that for an extended loss of all AC power, there is high confidence that the IFBs at Pickering NGS will be maintained adequately filled and the irradiated fuel adequately cooled using existing IFB coolant make-up strategies and augmented by EME pumps. FAI 1.6.1 is closed. This conclusion is not impacted by extended operation. Note that OPG is in the process of updating IFB Condition Assessments in support of extended operation.		No gap

#	Fukushima Action Item [3]	Assessment of Impact of Operation Beyond 2020		Results
		Pickering Units 1,4	Pickering Units 5-8	
11	FAI 1.6.2 A plan and schedule for deployment of any additional mitigating measures shown to be necessary by the evaluation of structural integrity. December 2013.	As outlined in Reference [4], it has been determined that expected leakage is well within the capability of additional water sources, such as EME, to mitigate. FAI 1.6.2 is closed. This conclusion is not impacted by extended operation.		No gap
12	FAI 1.7.1 A plan and schedule for optimizing existing provisions (to provide coolant makeup to Primary Heat Transport System, Steam Generators, moderator, etc.) and putting in place additional coolant make-up provisions, and supporting analyses. December 2013.	As outlined in Reference [4], EME was successfully deployed. FAI 1.7.1 is closed. This conclusion is not impacted by extended operation.		No gap
13	FAI 1.8.1 A detailed plan and schedule for performing assessments of equipment survivability, and a plan and schedule for equipment upgrade where appropriate based on the assessment. December 2013.	An assessment [4] has demonstrated that there is reasonable assurance that sufficient equipment and instrumentation will be available to facilitate operator actions at Pickering under a wide range of BDBA conditions, and hence no further actions are required. FAI 1.8.1 is closed. This conclusion is not impacted by extended operation.		No gap

#	Fukushima Action Item [3]	Assessment of Impact of Operation Beyond 2020		Results
		Pickering Units 1,4	Pickering Units 5-8	
14	FAI 1.9.1 An evaluation of the habitability of control facilities under conditions arising from beyond-design basis and severe accidents. Where applicable, detailed plan and schedule for control facilities upgrades. December 2014.	As outlined in Reference [4], for Pickering 1,4 and 5-8, plant habitability assessments were performed. The Pickering habitability assessment indicates that OPG's installed and planned upgrades and additional lines of defence (see FAI 1.7.1 which is complete) are sufficient to terminate event progression at or before the early In Vessel Retention stage, thereby supporting station habitability and providing reasonable confidence that essential operator actions can be completed in a timely manner. FAI 1.9.1 is closed. This conclusion is not impacted by extended operation.		No gap
15	FAI 1.10.1 An evaluation of the requirements and capabilities for electrical power for key instrumentation and control. The evaluation should identify practicable upgrades that would extend the availability of key I&C, if needed. December 2012.	As outlined in Reference [4], OPG has completed a comprehensive assessment demonstrating that adequate provisions are in place to ensure electric power supply is available to essential instrumentation and equipment. Following an extended loss of all AC power, the plant can rely on station battery back-up power, followed by the use of EME equipment including temporary portable uninterruptible power supplies if required as a bridging strategy, and then portable EME electrical generators. FAI 1.10.1 is closed. This conclusion is not impacted by extended operation.		No gap
16	FAI 1.10.2 A plan and schedule for deployment of identified upgrades. A target of 8 hours without the need for offsite support should be used. December 2012.	As outlined in Reference [4], OPG has completed a comprehensive assessment demonstrating that adequate provisions are in place to ensure electric power supply is available to essential instrumentation and equipment. Following an extended loss of all AC power, the plant can rely on station battery back-up power, then portable uninterruptible power supplies if required as a bridging strategy, and followed by the use of EME equipment including temporary portable EME electrical generators. FAI 1.10.2 is closed. This conclusion is not impacted by extended operation.		No gap

#	Fukushima Action Item [3]	Assessment of Impact of Operation Beyond 2020		Results
		Pickering Units 1,4	Pickering Units 5-8	
17	FAI 1.11.1 A plan and schedule for procurement (of emergency equipment and other resources that could be stored offsite). December 2012.	As outlined in Reference [4], OPG committed to undertake this work for all OPG nuclear stations as part of its Emergency Mitigating Equipment project (see FAI 1.7). Subsequently OPG procured emergency equipment covered by FAI 1.11.1. FAI 1.11.1 is closed. This conclusion is not impacted by extended operation.		No gap
18	FAI 2.1.1 Re-evaluation, using modern calculations and state of the art methods, of the site specific magnitudes of each external event to which the plant may be susceptible. December 2013.	As outlined in Reference [4], the re-evaluation of external events has been completed. For Pickering, the screening analyses were completed in 2012. The assessment of the unscreened events is detailed in FAI 2.1.2. FAI 2.1.1 is closed. This conclusion is not impacted by extended operation.		No gap
19	FAI 2.1.2 Evaluate if the current site specific design protection for each external event assessed in 1 above is sufficient. If gaps are identified a corrective plan should be proposed. December 2013.	As outlined in Reference [4]: As described in FAI 2.1.1, two unscreened hazards were identified at Pickering 1,4 and 5-8: high winds and seismic events. For Pickering 1,4 and 5-8 analysis of high winds and seismic events was completed. For Pickering 1,4, EME was credited to provide mitigation for some severe wind events considered in these analyses. It was determined that mitigating actions to secure EME to prevent failure and/or impairment resulting from high winds would be beneficial and these actions were undertaken.		No gap

#	Fukushima Action Item [3]	Assessment of Impact of Operation Beyond 2020		Results
		Pickering Units 1,4	Pickering Units 5-8	
		For Pickering 5-8, the high wind PRA estimated the Severe Core Damage Frequency (SCDF) for high winds with a recurrence interval of 10,000 years to be within OPG's safety goal target. A PRA-based Seismic Margin Assessment was completed for Pickering 1,4 and 5-8. The results demonstrate satisfactory station performance under seismic events. A review of seismically induced fires and floods was completed for Pickering 1,4 and Pickering 5-8. The assessment did not identify any fire or flood sources that would significantly affect the estimate of SCDF in the seismic PRA. (Reference [4]) FAI 2.1.2 is closed. This conclusion is not impacted by extended operation.		
20	FAI 2.2.1 Site-specific implementation plans for RD-310. December 2013.	As outlined in Reference [4], the Pickering RD-310 implementation plan was developed and was discussed with CNSC staff in February 2013. The Pickering implementation plan was subsequently submitted to the CNSC. CNSC closed FAI 2.2.1 following formal submission of the Pickering RD-310 implementation plans. As outlined in Reference [8], subsequently, the CNSC replaced RD-310 with REGDOC-2.4.1, and OPG developed a REGDOC-2.4.1 implementation plan. In Reference [8], OPG's response to FAI 2.2.1 is reassessed in the context of extended operation. The conclusion of that reassessment was that the 2014-2017 REGDOC-2.4.1 Implementation Plan for Pickering remains valid. Under this plan, new Safety Report Appendices to address Common Mode Events are being developed, consistent with the graded approach. Note that REGDOC-2.4.1 is in the assessment basis for Pickering PSR2, and the results of the review will be considered in the PSR2 Global Assessment.		No gap

#	Fukushima Action Item [3]	Assessment of Impact of Operation Beyond 2020		Results
		Pickering Units 1,4	Pickering Units 5-8	
21	FAI 3.1.1 Where SAMG has not been developed/finalized or fully implemented; provide plans and schedules for completion. December 2013.	As outlined in Reference [4], plans and schedules were developed, and Severe Accident Management Guidance (SAMG) has been implemented for all Pickering units. FAI 3.1.1 is closed. This conclusion is not impacted by extended operation.		No gap
22	FAI 3.1.2 For multi-unit stations, provide plans and schedules for the inclusion of multi-unit events in SAMGs. December 2013.	As outlined in Reference [4], a detailed plan and schedule for the explicit inclusion of multi-unit effects and consideration in SAMG was prepared and submitted to CNSC. SAMGs have been updated for multi-unit events. FAI 3.1.2 is closed. This conclusion is not impacted by extended operation.		No gap
23	FAI 3.1.3 For all stations, plans and schedules for the inclusion of IFB events in station operating documentation where appropriate. December 2013.	As outlined in Reference [4], evaluations of IFB loss of cooling events were prepared for all Pickering IFBs. Procedural revisions to improve the station response to events in the IFBs were completed. Additional portable EME was procured and usage guidelines implemented at Pickering for responding to IFB events following a total loss of AC power. FAI 3.1.3 is closed. This conclusion is not impacted by extended operation.		No gap
24	FAI 3.1.4 Demonstration of effectiveness of SAMGs via table-top exercise and drills. December 2013.	As outlined in Reference [4], Severe Accident Management Guidance table-top exercises and drills have been conducted at Pickering. FAI 3.1.4 is closed. This conclusion is not impacted by extended operation.		No gap

#	Fukushima Action Item [3]	Assessment of Impact of Operation Beyond 2020		Results
		Pickering Units 1,4	Pickering Units 5-8	
25	FAI 3.2.1 An evaluation of the adequacy of existing modeling of severe accidents in multi-unit stations. The evaluation should provide a functional specification of any necessary improved models. December 2012.	As outlined in Reference [4], the assessment of severe accident modelling in a multi-unit station was jointly prepared by OPG and Bruce Power. FAI 3.2.1 is closed. This conclusion is not impacted by extended operation.		No gap
26	FAI 3.2.2 A plan and schedule for the development of improved modeling, including any necessary experimental support. December 2012.	As outlined in Reference [4], OPG has completed an assessment demonstrating that the current modeling techniques used to assess the impact and consequences of multi-unit events at the Pickering station are sufficient. FAI 3.2.2 is closed. A multi-unit MAAP4-CANDU model was developed to confirm that the multi-unit severe accident progression and consequences are adequately simulated. Test cases demonstrated that modeling techniques are acceptable for multi-unit stations [7]. This conclusion is not impacted by extended operation.		No gap
27	FAI 4.1.1 An evaluation of the adequacy of existing emergency plans and programs. December 2012.	As outlined in Reference [4], the self-assessment and related evaluation of the emergency plan response capability completed in 2011, and resultant initiatives to resolve identified gaps met the intent of CNSC FAI 4.1.1. These initiatives are either complete or underway as either stand-alone projects or activities tracked by the OPG Action Tracking system. FAI 4.1.1 is closed. The required follow-up plan and schedule are considered in FAI 4.1.2. This conclusion is not impacted by extended operation.		No gap

#	Fukushima Action Item [3]	Assessment of Impact of Operation Beyond 2020		Results
		Pickering Units 1,4	Pickering Units 5-8	
28	FAI 4.1.2 A plan and schedule to address any gaps identified in the evaluation. December 2012.	As outlined in Reference [4], information on the evaluation of existing plans and programs is presented in the description for FAI 4.1.1. One of the initiatives from the post-Fukushima evaluation was to incorporate Beyond Design Basis Events (BDBE), including BDBA, into emergency plans. A BDBE accident scenario was prepared and used to benchmark the onsite emergency plan and review its earlier assessments for BDBA. The conclusion was that the existing Emergency Response Organization, command structure, staffing and governance are event-independent and adequate for BDBA. Gaps were identified related to: • Emergency Planning Basis to include BDBA (generic gap) • Site access • Public dose projection tool – Emergency Response Projection (ERP) • Dosimetry and radiation protection for large numbers of support staff. These gaps were addressed according to an approved plan and schedule. On this basis, FAI 4.1.2 is closed. This conclusion is not impacted by extended operation.		No gap
29	FAI 4.2.1 A plan and schedule for the development of improved exercise program. December 2012.	As outlined in Reference [4], the plan and schedule for an improved Emergency Preparedness exercise program was provided and accepted. FAI 4.2.1 is closed. This conclusion is not impacted by extended operation.		No gap
30	FAI 5.1.1 An evaluation of the adequacy of backup power for emergency facilities and equipment.	As outlined in Reference [4], providing a source of backup power to emergency facilities and equipment, including telecommunications and redundant emergency telecommunications, was an industry initiative based on initial Fukushima Operating Experience. OPG addressed this with a comprehensive review of its overall capability in 2011. At the CNSC's		No gap

#	Fukushima Action Item [3]	Assessment of Impact of Operation Beyond 2020		Results
		Pickering Units 1,4	Pickering Units 5-8	
	December 2012.	request, additional details related to this assessment were provided. Based on current perspectives and discussion with the regulator, this included an expanded review and revisiting a 2011 backup power resolution at the Pickering Emergency Operations Center with consideration of Human and Organizational Performance. FAI 5.1.1 is closed. This conclusion is not impacted by extended operation.		
31	FAI 5.1.2 A plan and schedule to address any gaps identified. December 2012.	As outlined in Reference [4], detail on the evaluation of the adequacy of backup power for emergency facilities and equipment is presented under FAI 5.1.1 above. Back-up power for Pickering's emergency facilities and equipment was deemed adequate. FAI 5.1.2 is closed. This conclusion is not impacted by extended operation.		No gap
32	FAI 5.2.1 Identify the external support and resources that may be required during an emergency. December 2012.	As outlined in Reference [4], FAIs 5.2.1, 5.2.2 and 5.2.3 were being managed as a common action for OPG. OPG has agreements in effect with relevant external agencies to support emergency response. As a post-Fukushima collaborative enhancement, OPG and four other major Canadian nuclear operators formalized a Mutual Aid Agreement. FAI 5.2.1 is closed. This conclusion is not impacted by extended operation.		No gap
33	FAI 5.2.2 Identify the external support and resource agreements that have been formalized and documented. December 2012.	As outlined in Reference [4], FAIs 5.2.1, 5.2.2 and 5.2.3 were being managed as a common action for OPG and actions have been completed. FAI 5.2.2 is closed. This conclusion is not impacted by extended operation.		No gap

#	Fukushima Action Item [3]	Assessment of Impact of Operation Beyond 2020		Results
		Pickering Units 1,4	Pickering Units 5-8	
34	FAI 5.2.3 Confirm if any undocumented arrangements can be formalized. December 2012.	As outlined in Reference [4], FAIs 5.2.1, 5.2.2 and 5.2.3 were being managed as a common action for OPG. FAI 5.2.3 is closed. This conclusion is not impacted by extended operation.		No gap
35	FAI 5.3.1 Provide a project plan and installation schedule. December 2012.	As outlined in Reference [4], OPG has installed an automated Near Boundary Gamma Monitoring System to coincide with the location of the Thermo-Luminescent Dosimeter (TLD) Near Boundary sites at the site boundary (nominally 1 km from the plant) at Pickering. These monitors are solar powered with an 8-hour battery backup and provide immediate information on dose rates at the site boundary to the plant. FAI 5.3.1 is closed. This conclusion is not impacted by extended operation.		No gap
36	FAI 5.4.1 Develop source term and dose modeling tools specific to each NPP. December 2012.	Not Applicable [3]. OPG has these measures already in place and therefore, this action does not apply to OPG [4]. This conclusion is not impacted by extended operation.		No gap

5.0 RESULTS AND CONCLUSIONS

Based on the assessment in Table 1, OPG's responses to the FAIs assigned to Pickering NGS remain valid in the context of extended operations beyond 2020. There are no additional gaps identified that must be considered in the PSR2 Global Assessment based on this review.

Subject: Pickering NGS: Periodic Safety Review 2 - CNSC Staff Review of OPG Global Assessment Report (GAR), Revision 1

Dear Mr. Lockwood:

Canadian Nuclear Safety Commission (CNSC) staff have reviewed OPG Global Assessment Report (GAR) Revision 1 [1] produced under Pickering Periodic Safety Review 2 (PSR2).

CNSC staff determined that this Revision 1 of the GAR satisfies the regulatory requirements of CNSC REGDOC-2.3.3, reflects the work performed under Pickering PSR2, and includes satisfactory disposition by OPG of CNSC staff comments in [2].

Should you have any queries, please contact Dr. Al Omar at al.omar@canada.ca or at 613-995-0565.

Yours truly,

Alexandre Viktorov, Ph.D.
Regulatory Program Director
Pickering Regulatory Program Division

Dear Dr. Viktorov:

Pickering NGS - Periodic Safety Review 2 – Submission of Global Assessment Report Revision 1

The purpose of this letter is to submit the Pickering Periodic Safety Review 2 (PSR2) Global Assessment Report Revision 1, P-REP-03680-00032-R001 (Enclosure 1).

This Global Assessment Report presents the results of the Pickering NGS PSR2 Global Assessment, completed in support of extended operation of Pickering NGS. The Pickering PSR2 has been conducted in accordance with the PSR2 Basis Document (Reference 1) that was accepted by the CNSC (Reference 2) and is consistent with CNSC REGDOC-2.3.3.

This revision to the Global Assessment Report includes minor enhancements to the earlier version (Revision 0) submitted for CNSC review (Reference 3) and incorporates comments received from the CNSC (Reference 4) as indicated in Attachment 1.

The Global Assessment Report consolidated findings identified from the Safety Factor review phase of the PSR2 project into Global Issues which were prioritized, assessed, and proposed Resolution Plans developed. The proposed Resolution Plans were supported by specific actions documented in the Integrated Implementation Plan that was submitted for CNSC staff acceptance in November 2017 (Reference 5).

The Global Assessment concludes that the Pickering NGS design, operation, processes and management system will ensure continued safe operation of Units 1,4 and 5-8, both in the short term, and for extended operation. Ontario Power Generation and the Pickering Station Leadership Team are committed to investing in the plant, and focusing the organization to strive for continued improvement in the plant condition, operation and performance.

If you have any questions, please contact Paulina Herrera, Manager, Pickering Regulatory Affairs at 905-839-1151 extension 3235.

Randy Lockwood
Senior Vice President
Pickering Nuclear

OPG's Responses to CNSC Staff Review of Global Assessment Report P-REP-03680-00032 Revision 0

The following table documents OPG's responses to the CNSC staff review of P-REP-03680-00032 R0 received in Reference A-1.

Table A-1: OPG's Responses to CNSC Staff Review of Global Assessment Report Revision 0

	Section # / Paragraph #	State the Issue	CNSC Staff Comment and Recommendation(s)	OPG Response
1.	SF6-1, SF6-2 (GI-27)	OPG links the resolution of GI-37 and GI-40 to the resolution of GI-27.	GI-37 and GI-40 are mainly design issues. GI-27 focuses on the plant risk improvement items given that all other plant design requirements (SF1 issues) would have been met or resolved. Although the final PSA results need to reflect the design and operation of the plant, meeting safety goals are not used to justify if the design requirements for containment systems can be relaxed. CNSC Staff request that OPG de-link the resolution of GI-27 (PSA modeling and identification of risk improvements) to the design requirements elements of GI-37 and GI-40. Even though the safety goals are met in GI-27, OPG remains obligated to meet the design requirements for the containment.	**Complete** The cross reference between GI-27 and GI-37 has been removed and enhanced wording added to GI-37 and GI-40 to better explain the relationship of how GI-37 is addressed by GI-40, and how these relate to the Risk Reduction activities in GI-27.
2.	Page C-18 GI-12: Extending the Env.	Paragraph 2 states "Regarding deterministic considerations, the Safety Significance	PSR2 Basis Document, e-docs# 5037878, page 63, Table E1, first column, third row, states: "A (safety) function is affected by the issue but the effect does not	**Complete** Both criteria are applicable; the second paragraph has been revised as shown below

Attachment 1 (Page 2 of 4) to OPG Letter, R. Lockwood to A. Viktorov, "Pickering NGS Periodic Safety Review 2 – Submission of Global Assessment Report Revision 1", CD# P-CORR-00531-05292.

	Section # / Paragraph #	State the Issue	CNSC Staff Comment and Recommendation(s)	OPG Response
	Qualification of Equipment Paragraph 2	Level determined from Table E1 in the PSR2 Basis Document is 3, since ensuring Environmental Qualification for extended operation will ensure the capability of safety provisions to effectively terminate an initiating event (first column, third row in Table E1 in the PSR2 Basis Document)."	impair the capability of safety provisions to terminate an anticipated serious process failure." OPG is required to explain in the GAR: 1) Why the Safety Significance Level was determined from Table E1 based on criteria impact on protection against process failures (first column) and not against design basis accidents (DBA) (second column), since EQ is applicable only to DBA. 2) How the following two cited statements are compatible: - OPG draft GAR, page C-18 'will ensure the capability of safety provisions to effectively terminate an initiating event' - PSR2 Basis Document, page 63, Table E1, first column, third row 'does not impair the capability of safety provisions to terminate an anticipated serious process failure.' If EQ for extended operation will ensure the capability of safety provisions to effectively terminate an initiating event, does it mean that lack of EQ for extended operation does not impair	to include the two criteria. Regarding the second part of the comment, the GI is related to a confirmatory activity, i.e., to confirm that Environmentally Qualified (EQ) equipment will continue to be EQ'd for the extended operating period. It is not about lack of EQ for any component. If the GI was intended to qualify previously unqualified equipment, then it might have been appropriate to select a higher Safety Significance Level. *"Regarding deterministic considerations, the Safety Significance Level determined from Table E1 in the PSR2 Basis Document is 3. This is because ensuring Environmental Qualification for extended operation will ensure the capability of safety provisions to effectively terminate an initiating event (first column, third row in Table E1 in the PSR2 Basis Document) and the issue does not affect the safety function capability for more than one level of protection (second*

Attachment 1 (Page 3 of 4) to OPG Letter, R. Lockwood to A. Viktorov, “Pickering NGS Periodic Safety Review 2 – Submission of Global Assessment Report Revision 1”, CD# P-CORR-00531-05292.

	Section # / Paragraph #	State the Issue	CNSC Staff Comment and Recommendation(s)	OPG Response
			the capability of safety provisions to terminate an anticipated serious process failure?	*column, third row in Table E1 in the PSR2 Basis Document). Safety Significance Levels (E2) is considered not applicable, since this Global Issue has a direct nuclear safety impact, whereas E2 primarily relates to issues that impact other objectives or are indirectly related to nuclear safety. The overall Safety Significance Level for deterministic considerations is 3.”*
3.	Page D-61, Appendix D, Section D-9	OPG has referenced “Section 5.0 of OPG Report [N-RPP-03415.1-10001-R07, *Radiation Protection Requirements - Nuclear Facilities*, June 25, 2001] in support of D-188 – Rad. Protection in Design. This document is obsolete and has been superseded by N-PROG-RA-0013, *Radiation Protection*. OPG should ensure they reference the correct document.	OPG should ensure they provide in the GAR the correct reference to address the design features captured on page 61, paragraph 2.	**Complete** Wording modified to include the superseding reference.

Attachment 1 (Page 4 of 4) to OPG Letter, R. Lockwood to A. Viktorov, "Pickering NGS Periodic Safety Review 2 – Submission of Global Assessment Report Revision 1", CD# P-CORR-00531-05292.

	Section # / Paragraph #	State the Issue	CNSC Staff Comment and Recommendation(s)	OPG Response
4.	Page D-61 Appendix D, Section D-9	OPG has provided the following information in support of quarterly reports submitted by OPG: *"Worker radiation dose due to events described in S-99 clauses 6.3.1 (7) or 6.3.1 (8) and the collective radiation dose of each group of workers."* This reference is obsolete and should be updated.	OPG should ensure they provide in the GAR the correct reference to address in their discussion of quarterly reports captured on page 61, paragraph 2.	**Complete** Wording modified to include the superseding reference.
5.	Page B-185	GI-50-RS1: "In addition, revise the Fuel Channel inspection and surveillance requirements to align with CSA N285.4-14"	OPG should remove this last sentence from the Resolution Statement since the Fuel Channel subject related to CSA N285.4-14 has its own Resolution Statement in GI-1.	**Complete** Statement related to fuel channels removed from GI-50-RS1 as it is already addressed in GI-1.

Executive Summary

This Global Assessment Report presents the results of the Pickering Nuclear Generating Station (NGS) Periodic Safety Review 2 (PSR2) Global Assessment, completed in support of extended operation of Pickering NGS. PSR2 has been conducted in accordance with the PSR2 Basis Document [1] and is consistent with Canadian Nuclear Safety Commission (CNSC) REGDOC-2.3.3 [2].

The current planning basis for Pickering NGS is operation of Pickering NGS Units 1,4 and 5-8 until the end of 2024. To align with the anticipated expiry date of the next Power Reactor Operating Licence (PROL), for the purposes of PSR2 only the period of extended operation of Pickering NGS units is considered to the end of 2028.

The Global Assessment concludes that the Pickering NGS design, operation, processes and management system will ensure continued safe operation of Units 1,4 and 5-8, both in the short term, and for extended operation. Ontario Power Generation (OPG) and the Pickering Station Leadership Team are committed to investing in the plant, and focusing the organization to strive for continued improvement in the plant condition, operation and performance. Pickering NGS units will be operated only if fitness for service of the structures, systems and components (SSCs) important to safety is assured.

In the Global Assessment, Gaps identified in the Safety Factor review phase are consolidated into Global Issues. The Global Issues are prioritized and assessed, and Resolution Plans are proposed. The proposed Resolution Plans will be supported by specific actions in the Integrated Implementation Plan.

The Global Assessment demonstrates that Pickering NGS will operate safely during the extended operating period. In addition, activities are in progress and planned that will further enhance safe plant operation. The justification for this conclusion is based on the following:

- The Pickering Station Leadership Team has effectively aligned the organization to significantly improve performance in a number of key focus areas. Station performance improvement has been recognized through industry reviews. The plant is safe, and is operated safely.
- OPG has comprehensive programs in place to ensure the condition of SSCs important to safety at Pickering Units 1,4 and 5-8 is well understood, to assess the level of fitness for service, and to effectively take action to maintain good plant condition. This has led to continuous improvement in the condition of the plant, and plant performance.
- OPG has made significant improvements to the Pickering NGS plant design and processes. The plant design enhancements, together with the process enhancements, closely align the plant with safety-significant requirements of modern codes and standards (which in some cases are beyond current requirements), and enhance defence-in-depth. In particular, enhancements made in response to the 2011 Fukushima accident have reduced, and will further reduce, the risk associated with Beyond Design Basis Accidents (BDBAs).

- Design and operation of the plant meet the current deterministic safety analysis dose limits, and processes are in place to ensure the safety analysis accounts for any additional aging effects associated with extended operation. The Probabilistic Safety Assessment (PSA) shows that the OPG risk-based Safety Goals for Core Damage Frequency and Large Release Frequency are met. Initiatives have been proposed to further enhance the margins to these goals.
- Radiological dose performance and environmental impact performance are significantly better than regulatory limits. Programs in place ensure the ongoing effectiveness of the radiological protection of workers, the public and the environment.
- The Global Assessment identifies 24 Strengths, indicating that Pickering NGS is well aligned with modern codes, standards and practices in key areas.
- The Global Assessment identifies 51 Global Issues. Resolution plans for Global Issues have been developed, and most are in progress to further enhance safety, including enhancements to further reduce the risk associated with BDBAs. Many of the Global Issue Resolution Plan actions reflect existing work programs and plans at the station. In particular, for the Global Issues of highest safety significance (i.e., fitness for service to cover the extended operating period), OPG was already fully aware of these issues and is actively working on addressing them for the extended operating period. None of the Global Issues identify a safety concern that requires additional planned or urgent action to be taken.
- The Global Issues of highest safety significance pertain to fitness for service of SSCs important to safety over the extended operating period. Units will be operated only if fitness for service of SSCs important to safety is assured. OPG has comprehensive programs in place to ensure the condition of SSCs important to safety is well understood, to assess the level of fitness for service, and to effectively take action to maintain good plant condition. The Resolution Plans for these Global Issues will ensure the ongoing fitness for service of SSCs for the operational life of the plant, and these plans are actively being progressed.
- The Global Assessment includes a Resolution Plan that proposes the investigation and implementation of design, operational, and/or analytical options to further enhance margins to risk-based Administrative Safety Goals.
- The assessment of Acceptable Deviations confirms there is no impact on the conclusion of the Global Assessment, either individually or in aggregate.
- The Defence-in-Depth Assessment shows that Pickering Units 1,4 and Pickering Units 5-8 design and operation have adequate and effective barriers in all levels of defence-in-depth.
- OPG’s organizational structure and management system provides the requisite processes, tools, resources and oversight that will ensure continued safe operation of the plant.

As noted, the Global Assessment concludes that the Pickering NGS design, operation, processes and management system will ensure continued safe operation of Units 1,4 and 5-8, both in the short term, and for extended operation.

Acronyms and Abbreviations

AD	Acceptable Deviation
AECL	Atomic Energy of Canada Limited (now Canadian Nuclear Laboratories)
AG	Additional Gap
ALARA	As Low As Reasonably Achievable
AOO	Anticipated Operational Occurrence
ASME	American Society of Mechanical Engineers
BDBA	Beyond Design Basis Accident
CANDU	CANada Deuterium Uranium
CCS	Concrete Containment Structure
CNSC	Canadian Nuclear Safety Commission
COG	CANDU Owners Group
COP	Continued Operations Plan
CRN	Canadian Registration Number
CSA	Canadian Standards Association
DBA	Design Basis Accident
ECI	Emergency Coolant Injection
EFPH	Effective Full Power Hours
EME	Emergency Mitigating Equipment
EMS	Energy Management System
EQ	Environmental Qualification
FADS	Filtered Air Discharge System
FAI	Fukushima Action Item
FFS	Fitness for Service
GI	Global Issue
HFE	Human Factors Engineering
HTS	Heat Transport System
IAEA	International Atomic Energy Agency

IAMP	Integrated Aging Management Program
IEC	International Electrotechnical Commission
IFB	Irradiated Fuel Bay

IIP	Integrated Implementation Plan
INPO	Institute of Nuclear Power Operations
ISO	International Standards Organization
ISR	Integrated Safety Review
KI	Potassium Iodide
LBLOCA	Large Break Loss of Coolant Accident
LCMP	Life Cycle Management Plan
LOCA	Loss of Coolant Accident
LOF	Loss of Flow
MCR	Main Control Room
NFA	No Further Action
NFPA	National Fire Protection Association
NGS	Nuclear Generating Station
NOP	Neutron Overpower Protection
NPP	Nuclear Power Plant
OPEX	Operating Experience
OPG	Ontario Power Generation
OSART	Operational Safety Review Team
PARTS	Pickering A Return to Service
PHT	Primary Heat Transport
PIP	Periodic Inspection Program
PROL	Power Reactor Operating Licence
PSA	Probabilistic Safety Assessment
PSR	Periodic Safety Review
PSR1	Periodic Safety Review 1
PSR2	Periodic Safety Review 2
RMS	Radionuclide Management System
RS	Resolution Statement
SBLOCA	Small Break Loss of Coolant Accident
SDS1	Shutdown System No. 1
SDS2	Shutdown System No. 2
SDSA	Shutdown System A (Original Shutdown System)
SDSE	Shutdown System Enhancement
SOE	Safe Operating Envelope

SSCs	Structures, Systems and Components
WANO	World Association of Nuclear Operators
XRF	Cross-Reference

Part I: Methodology

1. Purpose

OPG is conducting a Periodic Safety Review (PSR) in support of extended operation of Pickering NGS [1]. This work is a subsequent PSR for Pickering NGS, and is designated as PSR2. The work is being performed consistent with the requirements of CNSC REGDOC-2.3.3 *Periodic Safety Reviews* [2], which incorporates the requirements of International Atomic Energy Agency (IAEA) SSG-25 [3]. PSR2 is being conducted following the processes and schedule identified in the OPG-CNSC Protocol developed in support of the PSR2 execution interface [4].

The objective of the Global Assessment is to provide an overall assessment of the safety of the plant, and to assess the acceptability of Pickering NGS for continued operation over the PSR2 period, including an assessment of the defence-in-depth capability of Pickering NGS.

As noted in the PSR2 Basis Document [1], the current planning basis for Pickering NGS is that Pickering NGS units will operate until the end of 2024. To align with the anticipated expiry date of the next PROL, for the purposes of PSR2 only the period of extended operation of Pickering NGS units is considered to the end of 2028.

2. Background

OPG owns and is licensed to operate the Pickering NGS, which is located on the shore of Lake Ontario in the City of Pickering, in the Regional Municipality of Durham. The station has a total of eight CANada Deuterium Uranium (CANDU) reactors (Units 1 to 8). Currently, Pickering NGS Units 1,4 and 5-8 are operating, while Units 2 and 3 are no longer operational and are in a safe storage and surveillance state.

In accordance with CNSC REGDOC-2.3.3 [2], the elements of PSR2 consist of the following four phases:

(i) Preparation of a PSR2 Basis Document [1]

(ii) Conduct of the Safety Factor reviews and identification of Compliances and Gaps

(iii) Analysis of the Gaps and identification of potential safety enhancements for Pickering NGS in the Global Assessment process

(iv) Preparation of a plan for the implementation of safety enhancements (Integrated Implementation Plan)

The Pickering NGS PSR2 Basis Document [1] describes the scope and methodology for PSR2. PSR2 is a subsequent PSR; an update building on the review basis of earlier OPG PSR work and other associated assessments (termed here "PSR1").

Specifically, PSR1 consists of:

- The Pickering B Integrated Safety Review (ISR), completed in 2009 and performed in support of refurbishment and continued operation (at that time planned for another 30 years) of Pickering NGS Units 5-8.
- Pickering 1,4 integrated safety assessments performed during the Pickering A Return to Service (PARTS) work (circa 2000), in support of approval to restart Units 1 and 4.
- The relevant programmatic aspects of the Darlington ISR completed in 2011 in support of refurbishment and continued operation of the Darlington units (programmatic parts are applicable to Pickering where programs and practices are common for the OPG fleet).

The second phase of the PSR2 process involves completion of Safety Factor reviews. Safety Factors cover all aspects important to the safety of an operating Nuclear Power Plant (NPP). As identified in the PSR2 Basis Document [1], there are 15 Safety Factors used in the PSR2 review. These 15 Safety Factors are shown in Table 1.

Table 1: PSR2 Safety Factors

Subject Area	Safety Factor	
The Plant	SF1	Plant Design
	SF2	Actual Condition of Structures, Systems and Components Important to Safety
	SF3	Equipment Qualification (environmental and seismic)
	SF4	Aging
Safety Analysis	SF5	Deterministic Safety Analysis
	SF6	Probabilistic Safety Assessment
	SF7	Hazard Analysis
Performance and Feedback from Operating Experience	SF8	Safety Performance
	SF9	Use of Experience from other NPPs and Research Findings
Management	SF10	Organization, the Management System and Safety Culture
	SF11	Procedures
	SF12	Human Factors
	SF13	Emergency Planning
Environment	SF14	Radiological Impact on the Environment
Radiation Protection	SF15	Radiation Protection

The results of the Safety Factor reviews are documented in Safety Factor Reports. The Safety Factor Reports address the Review Tasks derived from IAEA SSG-25 for Safety Factors 1 to 14 and from CNSC REGDOC-2.3.3 for Safety Factor 15. The Safety Factor Reports also document the results of the assessments of Pickering NGS with respect to applicable modern Laws, Regulations, Codes and Standards, as listed in Appendix D of the PSR2 Basis Document [1], and OPG Program effectiveness reviews. Complementary Reviews, such as review of the Pickering B ISR Continued Operations Plan (COP) actions [5] and the Fukushima Action Items (FAIs) [6] were also completed in the Safety Factor phase.

The third phase of the PSR2 process, i.e., the Global Assessment, is documented in this Pickering NGS Global Assessment Report. The Global Assessment takes into account the Gaps identified during the Safety Factor reviews, the findings from Complementary Reviews (COP and FAI), and any findings from CNSC staff reviews of the Safety Factor Reports and Complementary Reviews. The Global Assessment includes consideration of the five levels of defence-in-depth, including consideration of Strengths, the enhancements proposed[1] through Global Issue Resolution Plans, and assessment of the aggregate impact of Acceptable Deviations, in order to make a conclusion on the overall acceptability of operation of the plant over the period considered in PSR2.

Preparation of the Integrated Implementation Plan, which is the fourth phase of the PSR2 process, involves transforming the proposed Resolution Plans resulting from the Global Assessment into actions with corresponding schedules for implementation during the next licensing period.

[1] At the Global Assessment stage, enhancements are identified as "proposed" through Global Issue resolutions. Enhancements are finalized at the Integrated Implementation Plan stage of the PSR2 process.

3. Overview of the Global Assessment Process

The major inputs to the Global Assessment are:

- Safety Factor Reports

  Gaps are listed in the Safety Factor Reports, based on the Review Tasks and assessments against modern Laws, Regulations, Codes and Standards.

- Complementary Reviews (FAIs, Pickering B ISR COP)

The above information is used to commence the Global Assessment process, which is based on the process outlined in the PSR2 Basis Document [1], and consists of the following elements:

1. Identification of Gaps from the Safety Factor Reports, Complementary Reviews (FAIs, Pickering B ISR COP), and any additional gaps that may be identified during the Global Assessment. Gaps arising from CNSC feedback on the PSR2 deliverables are also considered.
2. Development of Global Issues by integrating and consolidating the Gaps. Each Global Issue is comprised of Gaps related to a common theme.
3. Assessment of interfaces between the various Safety Factors, aggregate impact of Global Issues.
4. Prioritization of Global Issues.
5. Development of proposed Resolution Plans with consideration of safety benefit, practicability, and the interfaces between the Gaps and Global Issues.
6. Assessment of Defence-in-Depth, including Strengths, and the aggregate impact of Acceptable Deviations. It is noted that the PSR2 Basis Document also refers to residual Global Issues, but none were identified during the Global Assessment process.
7. Ranking of Global Issue Resolution Statements.
8. OPG senior management review of proposed Resolution Statements.
9. Assessment of overall acceptability of operation of the plant over the period considered in PSR2.
10. Preparation of the Global Assessment Report to summarize the assessments and document the Global Assessment.

Each of the above steps is described in more detail in Section 5 of this report. A pictorial representation of the Global Assessment Process is shown in Figure 1.

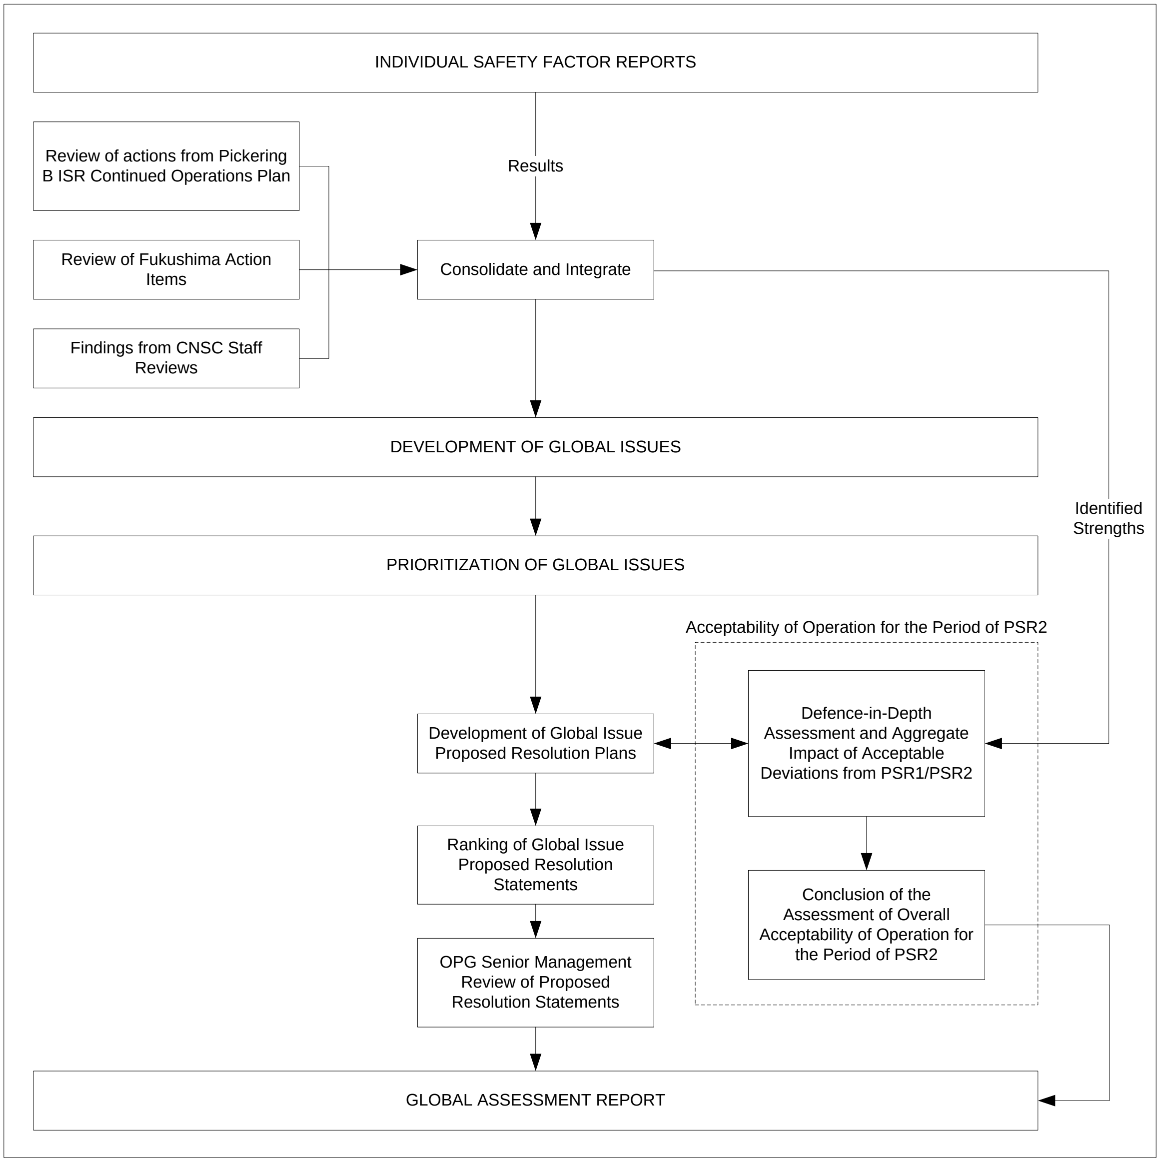

Figure 1: Pickering NGS Global Assessment Process Flowchart

4. Organization of the Report

This report is organized around the work done in each of the steps shown in Figure 1.

Part I: Methodology

Sections 1 and 2 describe the purpose and background of the Global Assessment. Sections 3 and 4 provide an overview of the Global Assessment process and the organization of this report, respectively. Section 5 describes the steps of the overall Global Assessment methodology.

Part II: Safety Factor and Complementary Review Summary

Sections 6 to 9 summarize the Gaps identified in the Safety Factor Reports, as well as the findings from the Complementary Reviews of the Pickering B ISR COP and FAIs, and CNSC feedback on the PSR2 Safety Factor Reports and Complementary Reviews.

Part III: Global Assessment

Section 10 summarizes the numbers of PSR2 Gaps from the various sources described in Part II of the Global Assessment Report. Section 11 groups the PSR2 Gaps into Global Issues, based on their topical similarities, and presents an assessment of the interfaces between the various Safety Factors and the aggregate impact of the Global Issues. Section 12 prioritizes the Global Issues, and Section 13 identifies proposed Resolution Plans for the Global Issues. Section 14 presents the results of the ranking of the proposed Global Issue Resolution Statements that will be considered in the Integrated Implementation Plan. The proposed Resolution Statements are ranked in order of the priority to resolve them based on the magnitude and timeliness of the benefit to be achieved by their resolution. Section 15 summarizes the findings resulting from a third party Expert Panel review of the Global Assessment.

Part IV: Assessment of Overall Acceptability of Operation of the Plant

Pickering NGS Strengths (Section 16) are evaluated for their contribution to the defence-in-depth capability of Pickering NGS (Section 18), which also considers the current Pickering NGS design and performance (Section 18.2) and the proposed Resolution Plans for Global Issues (Section 13). The Defence-in-Depth Assessment also considers the aggregate impact of the PSR1 Acceptable Deviations (Section 17), and PSR2 Acceptable Deviations (Appendix B).

Section 19 presents a justification for the overall acceptability of extended operation of the Pickering NGS.

Part V: References

Section 20 lists the references used in Parts I to IV of the Global Assessment Report.

Appendices

Appendices to the Global Assessment Report are presented at the end of the Global Assessment Report.

5. Global Assessment Methodology

This section describes the methodology for performing the Pickering NGS Global Assessment.

5.1. Identification of Gaps from the Safety Factor Reports and the Complementary Reviews

The first step in the Global Assessment methodology is the review and accumulation of the Gaps identified and described in each Safety Factor Report and other inputs to the Global Assessment (referred to as Complementary Reviews).

The following information for each Gap is also collected:

- Origin of Gap (i.e., Safety Factor Report Number, Complementary Review, other gaps)
- Gap identification number and title
- Associated Safety Factor review task (if applicable)
- Associated modern Laws, Regulations, Codes and Standards (if applicable)
- Relevant governing process or procedure (if applicable)
- Description of the Gap

5.2. Development of Global Issues

The second step in the Global Assessment methodology is the development of Global Issues. There are two aspects to this step, as follows:

- Consolidation of Gaps into Global Issues
- Assessment of the interfaces between the various Safety Factors and the aggregate impact of Global Issues

5.2.1. Consolidation of Gaps into Global Issues

Using the Gap information collected during the process described in Section 5.1, the Gaps are grouped into Global Issues according to their topical similarities, i.e., based on the related discipline, governing process or modern Laws, Regulations, Codes and Standards, with consideration of any interfaces or duplication between the Gaps. The following general steps are followed in consolidating the Gaps into Global Issues:

1. Gaps with clear similarity in themes or topical areas are consolidated into a specific Global Issue, e.g., governance issues where their resolution would require modification to OPG governance documentation. These Gaps are separated from those associated with the implementation or effectiveness of the governance, which are consolidated into a separate Global Issue identified as Governance Implementation/Effectiveness Issues.

The consolidation of Gaps also considers the expected differences between the level of importance of Gaps and their Resolution Plans, e.g., Gaps related to Major Components Fitness for Service (FFS) and Deaerator FFS are identified as separate Global Issues.

2. Any Gap against modern Laws, Regulations, Codes and Standard that is relevant to the theme or subject of an existing Global Issue is appropriately consolidated within the Global Issue.
3. The remaining Gaps that have not been consolidated into Global Issues are further re-examined to ensure their consideration as separate Global Issues is appropriate due to their specific nature.
4. If a Gap is found to be covered by another Gap within an existing Global Issue, it is clearly identified as such. If a Gap is found to be partly covered by an existing Global Issue, the coverage of the remaining part of the Gap is clearly specified in another Global Issue to ensure that the Gap is fully addressed.
5. A confirmatory step is completed to ensure that each Gap is appropriately consolidated into a Global Issue and potential interfaces between the Gaps from various Safety Factor Reports are accounted for.

Any additional Gaps identified during the Global Assessment work are appropriately integrated with the previously identified Gaps and Global Issues where applicable. By the end of this step, all Gaps are mapped to a Global Issue.

5.2.2. Assessment of Interfaces Between Various Safety Factors and Aggregate Impact of Global Issues

The third element of the Global Assessment process, as identified in Section 3.3.2 of the PSR2 Basis Document [1], is an assessment of “interfaces between the various Safety Factors, Aggregate Impact of Global Issues”. This step is carried out by first grouping Global Issues with the same or similar functional topic, independent of their origin from different Safety Factors or another source. For example, there are several Global Issues related to fitness for service, originating from Safety Factors 1, 2, 4 and the COP. These Global Issues are grouped together to form an aggregate group under the topic Fitness for Service. A similar approach is taken for the other Global Issues. In cases where a Global Issue is not related to any others, it is placed into a group with only a single Global Issue.

The second part of this element is completed after the Global Issue proposed Resolution Statements have been developed. Each Global Issue group is reviewed to determine if the interfaces among Global Issues originating from different Safety Factors or other sources warrants adjustment of proposed Resolution Plans for any Global Issue within the group. This review also considers whether the scope and nature of each Global Issue in a group, and the proposed Resolution Plan for each, would interact with or inhibit the successful resolution of any other Global Issues in the group. In either case, the aggregate effect of the Global Issues within the group could be more significant than the sum of the individual Global Issues, and revision of proposed Resolution Plans could be required.

The aggregate assessment considers the number of Global Issues in each aggregate group, the sources of associated Gaps, relevant OPG programs and the Global Issue Resolution Plans developed in Section 13.

5.3. Prioritization of Global Issues

The Global Issues developed in Section 5.2 are prioritized with respect to nuclear safety into one of four categories, based on their Safety Significance Level as described in Section 3.3.3 of the PSR2 Basis Document [1], and shown in Table 2.

Table 2: Safety Significance Level versus Impact on Nuclear Safety

Safety Significance Level	Impact on Nuclear Safety
1	High
2	Medium
3	Low
4	Very Low

The basis for prioritization of the Global Issues is provided in Appendices E and F of the PSR2 Basis Document [1], and includes deterministic and probabilistic considerations. The process is similar to that used in previous OPG ISRs and is used in PSR2 to prioritize Global Issues with respect to their importance to nuclear safety to determine the Safety Significance Level associated with each Global Issue. This supports the resolution evaluation and outcome of the resolution process.

For the purposes of Global Issue prioritization, and to be consistent with the PSR2 Basis Document [1], Table E1 of the PSR2 Basis Document is applied when the Global Issue may have a direct impact on the physical barriers associated with deterministic defence-in-depth considerations, or the other direct factors considered in the table, e.g., initiating events, safety culture. Table E2 is applied when the Global Issue may impact defence-in-depth indirectly or has no impact on defence-in-depth. A broader interpretation of defence-in-depth is applied in the Defence-in-Depth Assessment documented in Section 18 of this report, which considers Global Issues that affect defence-in-depth both directly and indirectly.

The outcome of the Global Issue Safety Significance Level assessment is documented in Section 4 of each Global Issue summary in Appendix B of this report. A Safety Significance Level between 1 and 4, or N/A, is assigned for each of the considerations in Appendix E and Appendix F of the PSR2 Basis Document [1]. N/A means that the Global Issue has no impact on the particular consideration, so the corresponding table in the PSR2 Basis Document is not applicable for the purposes of assessing the Safety Significance Level. The overall Safety

Significance Level for each Global Issue corresponds to the highest impact on nuclear safety (smallest Safety Significance Level number) of the individual considerations.

5.4. Development of Proposed Resolution Plans

Proposed Resolution Plans for the identified Global Issues are formulated with consideration of interfaces between the various Gaps to ensure that the proposed Resolution Plans complement each other. Proposed Resolution Plans are developed for all Global Issues, and consider safety benefit and practicability. Insights from available site Probabilistic Safety Assessments may be used in evaluating the benefit/practicality of potential options, where appropriate.

Proposed Resolution Plans may include proposed Resolution Statements which are actions defined to address a Gap. Proposed Resolution Statements are primarily proposed for Global Issues that have been prioritized with a Safety Significance Level of 1 or 2 (i.e., high or medium impact on nuclear safety), and for Global Issues with Safety Significance Level 3 if a practicable solution is readily evident.

Consistent with Section 3.3.3 of the PSR2 Basis Document [1], Resolution Statements are not proposed for all PSR2 Gaps. Gaps with Safety Significance Level 4 (i.e., very low impact on nuclear safety) are generally assessed as Acceptable Deviations. Gaps with Safety Significance Level 3 (i.e., low impact on nuclear safety) for which a practicable solution is not readily evident are also assessed as Acceptable Deviations. Acceptable Deviations are not tracked beyond the Global Assessment phase of PSR2 [1]. However, the impacts of Acceptable Deviations are considered in the Defence-in-Depth Assessment (refer to Section 5.7) to determine the aggregate impact on the defence-in-depth capability of the plant.

The PSR2 Basis Document [1] also describes the potential for residual Global Issues to be identified in the Global Assessment process. These would comprise aspects of a Global Issue for which a proposed Resolution Statement is not identified, nor is the issue an Acceptable Deviation or categorized as requiring No Further Action. However, no residual Global Issues were identified in the Global Assessment process, hence this topic is not discussed further in this report.

The proposed Global Issue Resolution Plans for each Global Issue are documented in Appendix B – Global Issues and Proposed Resolution Plans. These consist of the following statement types:

- Resolution Statements (RS): An activity is defined to address the Gap(s).
- No Further Action (NFA): Work is already completed or is underway outside of PSR2 to address the related Gap(s), or information has been found to obviate the Gap(s).
- Acceptable Deviation (AD): The Gap(s) have been assessed to have a Very Low Safety Significance Level, or are Low Safety Significance Level items and a practicable resolution is not readily evident.
- Cross Reference (XRF): An action that addresses the Gap(s) is covered by another Resolution Statement.

In conducting the Global Assessment, as Global Issue Resolution Plans are developed, consideration is given as to whether the resolution activities would be different for a scenario with operation to 2024 (the nominal planning basis for the units), or for operation beyond 2024. If the proposed Resolution Plan for a particular Global Issue may be dependent on whether plant operation is assumed to continue beyond 2024, the Global Issue Resolution Plan is flagged accordingly in Section 1 of each Global Issue Table in Appendix B, under a category entitled “Reassessment Beyond 2024”. In such cases where “Reassessment Beyond 2024” is identified as “Y”, detailed resolution activities are only identified to cover the period to 2024. If a decision is subsequently made to operate beyond 2024, the flagged Global Issue will need to be re- evaluated and updated actions will be identified for the proposed Global Issue Resolution Plan if/as appropriate.

To facilitate binning of potential work, proposed Resolution Plans are categorized as one or more of the following types of enhancements:

- Programmatic (changes to governing programs and procedures)
- Engineering (design changes)
- Analytical (engineering analysis, deterministic safety analysis, probabilistic safety assessment or hazard analysis)

The categorization is identified in Section 1 of each Global Issue Table in Appendix B. In some cases, the proposed Resolution Statements entail work in more than one of these categories.

5.5. Ranking of Resolution Statements

The purpose of ranking proposed Resolution Statements is to determine the activities that will be most effective in enhancing safety given the limited extended operating period of the plant. The ranking process recognizes that there are many factors that have to be taken into account in determining the rank of a specific proposed Resolution Statement, but a key consideration is that the ranking takes place within the context of the specific time period related to extended operation. Activities that will take a relatively long time to implement or to take effect may have relatively little practical benefit if the period of extended operation is short.

All Global Issue Resolution Statements with identified actions are ranked from 1 to N in decreasing importance such that 1 is the most important and N, which is the total number of Resolution Statements, is the least important. The ranking is determined through the application of a value-tree method for solving multi-attribute decision problems, as described in Appendix C. Acceptable Deviations and No Further Action statements do not go through the ranking process; only proposed Resolution Statements with identified actions are ranked.

The Value Tree for PSR2 ranking identifies an overall objective for PSR2 as “Enhanced confidence in the continued safe operation of PNGS for the period of PSR2”, with the following fundamental objectives that support this overall objective:

- Enhanced confidence that the design of SSCs supports modern safety practices
- Enhanced confidence in the fitness for service of SSCs

- Enhanced confidence in the Safety Analysis
- Enhanced confidence in safety performance and feedback of experience
- Enhanced confidence in the management processes
- Enhanced confidence in radiation and environmental protection

Using a pair-wise comparison, the above six fundamental objectives are ranked in terms of importance on a scale from 1 to 9.

A relative weight for each fundamental objective is then calculated and accordingly every proposed Resolution Statement is assigned the weight of the fundamental objective that is most relevant to it.

The ranking of each proposed Resolution Statement is based on the weight and a two-variable utility function that accounts for impact and time attributes. The impact attribute is a measure of how directly or strongly the issue impacts the objective while the time attribute accounts for how long it would take to implement and realize the associated objective. Each attribute is rated on a scale of 1 to 5.

The two-variable utility function is used to generate a utility matrix, and the time and impact ratings for each proposed Resolution Statement are used together with the utility matrix to obtain a numerical value that represents the utility score for resolving the proposed Resolution Statement. The Ranking Number of the proposed Resolution Statement is then calculated by multiplying its utility score by its weight.

As a final step, the rankings of the proposed Resolution Statements are confirmed based on engineering judgment applied by the Global Assessment team, and feedback from OPG staff and members of a third party Expert Panel (as described in Section 5.6.1). This considers factors such as the priority previously determined (Safety Significance Level), the contribution to defence-in-depth and the significance of the source (e.g., the type of document that generated the Gap(s) leading to the Global Issue). This also accounts for the extent of impact on multiple Safety Factors.

5.6. Review of Gaps, Global Issues and Proposed Resolution Plans

In addition to initial internal review by the Global Assessment Report preparation team, the Global Issues and proposed Resolution Statements and their rankings undergo a number of subsequent reviews during the Global Assessment process. These subsequent reviews are performed sequentially, as follows:

1. Third party Expert Panel review
2. Review by OPG's PSR2 project staff members and OPG Subject Matter Experts
3. Review and approval of proposed Resolution Statements by OPG's Senior Management Scope Review Board

The functions of the Expert Panel and the Senior Management Scope Review Board are described below.

5.6.1. Pickering PSR2 Expert Panel

The PSR2 Expert Panel is comprised of experienced individuals who are familiar with the design and operation of Pickering NGS (and other nuclear plants) and has been established to provide third party support to the PSR2 process. The Expert Panel has a broad mandate in terms of its activities, including providing third party guidance during the development and preparation of the Global Assessment Report. The framework for the Expert Panel activities is informed by, and is consistent with, the following documents:

- OPG P-REP-03680-00001, *Pickering NGS Periodic Safety Review 2 (PSR2) Basis Document* [1]
- CNSC REGDOC-2.3.3, *Periodic Safety Reviews* [2]
- IAEA INSAG-10, *Defence in Depth in Nuclear Safety* [7]
- IAEA SRS-46, *Assessment of Defence in Depth for Nuclear Power Plants* [8]
- IAEA SSG-25, *Periodic Safety Review of Nuclear Power Plants* [3]
- IAEA INSAG-12, *Basic Safety Principles for Nuclear Power Plants* [9]

In particular, the Expert Panel activities include third party review of the development of the Global Issues, their prioritization and proposed Resolution Plans, the defence-in-depth review, ranking of proposed Resolution Statements, and the overall assessment of safety.

The objectives of the Expert Panel third party review of Global Issues and proposed Resolution Plans are:

- For each Global Issue, review and agree that the associated Gaps identified in the Global Issue are appropriate.
- For each Global Issue, provide agreement that the Resolution Plan is complete (i.e., resolves the Gaps to the extent practicable).
- For each Global Issue, concur with the Resolution Category (i.e., programmatic, engineering or analytical).
- Agree that Acceptable Deviations are clearly understood and have appropriate rationale.
- Concur that the prioritization of Global Issues is consistent across the Global Assessment.
- Identify additional Gaps, and provide any other pertinent feedback to the Global Assessment team and to OPG staff.

The objectives of the Expert Panel third party review of the Defence-in-Depth Assessment and Global Issue Resolution Statement ranking are:

- Review and comment on the overall defence-in-depth methodology and results.
- Review and comment on the Resolution Statement ranking methodology and results.

In addition to the above activities, the Expert Panel also provides a closing third party review of the Global Assessment Report, including the overall assessment of safety, and states whether the Panel concurs with the conclusions of the Global Assessment.

5.6.2. Senior Management Scope Review Board

The proposed enhancements identified in the PSR2 Global Assessment Report are presented to the OPG Senior Management Scope Review Board for their review and approval. This provides an opportunity for the senior management team to suggest clarifications, confirm the best available options are recommended, or propose changes to enhance safety where such improvements are identified. The Scope Review Board also reviews the PSR2 Acceptable Deviations and No Further Action statements.

This review ensures alignment with the Resolution Plans proposed, their basis and context, and is the means to obtain concurrence that the proposed enhancements are practicable and effective. This also allows the senior management team to consider potential realignment of priorities based on the insights from PSR2. Consistent with OPG Project Management processes, additional approvals are required as the resolution development continues towards full implementation.

The Terms of Reference for the Senior Management Scope Review Board is documented in Reference [10].

5.7. Defence-in-Depth Assessment

As part of the Global Assessment, a Defence-in-Depth Assessment is performed as summarized below and described in more detail in Section 18.

The Defence-in-Depth Assessment supports extended operation of Pickering NGS by demonstrating the extent to which the safety requirements of defence-in-depth are fulfilled.

For each level of defence, the assessment considers the overall plant, as well as the Strengths and the proposed Resolution Plans for the Global Issues identified in PSR2. The impacts of Acceptable Deviations are also assessed to determine the aggregate impact on the defence-in-depth capability of the plant.

Strengths for consideration in the Defence-in-Depth Assessment are identified based on:

- PSR2 Safety Factor reviews and Complementary Reviews.
- Other plant reviews and stakeholder input.
- CNSC Regulatory Oversight Report findings.

The defence-in-depth concept applied to the Global Assessment is consistent with IAEA INSAG-10, *Defence in Depth in Nuclear Safety* [7]. The assessment uses elements of the process described in IAEA SRS-46, *Assessment of Defence in Depth for Nuclear Power Plants* [8], and includes the following:

- Confirmation of the applicable safety principles from IAEA SRS-46 [8] for the defence-in-depth review.
- Establishment of the levels of defence-in-depth impacted for each applicable safety principle (taken from IAEA SRS-46 [8]).
- Mapping of each safety principle to the relevant Safety Factors.
- Assessment of the defence-in-depth aspects of each safety principle in the Pickering NGS design and operation at a high level.
- Consideration of proposed Global Issue Resolution Plans.
- Consideration of Strengths identified during the assessment.
- Consideration of the Acceptable Deviations from PSR1 that are applicable to PSR2.
- Consideration of the Acceptable Deviations identified during the conduct of PSR2.
- For each level of defence, an overall summary integrating the conclusions from the assessment of the related safety principles, Strengths, proposed Resolution Statements and assessment of the aggregate impact of Acceptable Deviations on the defence-in-depth capability of the plant.
- An overall defence-in-depth conclusion summarizing the multiple and overlapping provisions considered in the assessment which support the levels of defence.

5.8. Conclusion of the Assessment of Overall Acceptability of Plant Operation

This step assembles the results of the previous steps in the Global Assessment to assess the overall acceptability of extended operation of Pickering NGS over the designated PSR2 period, on the basis of a balanced view of all of the findings. The assessment includes all aspects of plant operation, and considers the proposed enhancements identified, the Strengths, the assessment of provisions for all levels of defence-in-depth, and the aggregate impact of Acceptable Deviations.

Part II: Safety Factor and Complementary Review Summary

Section	
#	**Title**
6	Review of Safety Factor Reports and Identification of Gaps
7	Review of the Pickering B ISR Continued Operations Plan
8	Review of Fukushima Action Items
9	Findings from CNSC Staff Reviews of Safety Factor Reports and Complementary Reviews

6. Review of Safety Factor Reports and Identification of Gaps

This section summarizes the results of each of the 15 PSR2 Safety Factor Reports and lists the Gaps identified from each Safety Factor Report. The Safety Factor Report summaries are grouped into six subject areas, as follows:

- The Plant
- Safety Analysis
- Performance and Feedback from Operating Experience
- Management
- Environment
- Radiation Protection

6.1. The Plant

6.1.1. SF1: Plant Design

6.1.1.1. Objective

The objective of the review of Safety Factor 1, Plant Design, is to determine the adequacy of the design of the NPP and its documentation by assessment against the current licensing basis and national and international standards, requirements and practices.

6.1.1.2. Scope of the Review

The PSR2 review of Safety Factor 1 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25, *Periodic Safety Review of Nuclear Power Plants* [3] and CNSC REGDOC-2.3.3 [2]:

   RT1) Confirm that a detailed description of the plant design, documenting the Design Basis, supported by layout, system and equipment drawings exists.

   RT2) Assess the adequacy of design documentation.

   RT3) Identify the SSCs important to safety (Appendix B of the PSR2 Basis Document [1]).

RT4) Review the application of defence-in-depth. This includes an examination of:
- The degree of independence of the levels of defence-in-depth.
- The adequacy of delivery of preventive and mitigatory safety functions.
- Redundancy, separation and diversity of SSCs important to safety.
- Defence-in-depth in the design of structures (e.g., review of integrity of Fuel, cooling circuit and Containment building).

RT5) Confirm that the human-machine interface is considered in the design of the Control Room and other workstations, that analysis of human information requirements and task workload is performed, and that there is linkage to the Probabilistic Safety Assessment, Deterministic Safety Analysis and Hazard Analysis. This review should include a discussion of how guidance such as U.S. NRC NUREG-0700 Revision 2, *Human-System Interface Design Review Guidelines* and NUREG-0711 Revision 2, *Human Factors Engineering Program Review Model* identified in CNSC REGDOC-2.5.2 are relevant to the design of Pickering Units 1,4 and 5-8. (Note: In PSR1, a similar Review Task was addressed in the Human Factors Safety Factor. As it is the only Human Factors activity that deals with plant design it is being assessed as a PSR2 Plant Design Review Task).

RT6) Assess the adequacy of the arrangements for providing radiological protection.

RT7) Where the plant has undergone a significant number of modifications over its lifetime or in the period since PSR1, examine the cumulative effects of all modifications on the design.

RT8) Confirm that the plant SSCs are compliant with the design specifications and consistent with the design documentation.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.

3. Reviewing the effectiveness of the following applicable OPG Nuclear Programs that support the above assessments, through a review of audit and self-assessment results[2].

Document Number	Document Title
N-PROG-MP-0007	Conduct of Engineering
N-PROG-MP-0006	Software
N-PROG-MP-0005	Configuration Management
N-PROG-MP-0009	Design Management

The modern Laws, Regulations, Codes and Standards assessed in the review of this Safety Factor, along with the type of assessment conducted for each, are identified in Appendix A. The

[2] Although there may be content in Nuclear Programs that is applicable to multiple Safety Factors, each N-PROG review is only documented in one Safety Factor Report.

basis for the types of assessments performed is provided in Section 2.2 of the Safety Factor 1 Report [11].

6.1.1.3. Summary and Conclusions

Table 3 lists the thirty-six PSR2 Gaps identified in the Safety Factor 1 report [11], together with the source of each Gap and the associated Global Issue number.

The Safety Factor 1 report states that the review “has confirmed, by assessment against the current licensing basis and applicable standards, requirements and practices, that the design of Pickering NGS and its documentation is adequate” [11].

6.1.2. SF2: Actual Condition of Structures, Systems and Components Important to Safety

6.1.2.1. Objective

The objective of the review of Safety Factor 2, Actual Condition of Structures, Systems and Components Important to Safety, is to “determine the actual condition of SSCs important to safety and so to consider whether they are capable and adequate to meet design requirements, throughout the period of PSR2. In addition, the review should verify that the condition of SSCs important to safety is properly documented, as well as reviewing the ongoing maintenance, surveillance and in-service inspection programmes, as applicable” [1].

6.1.2.2. Scope of the Review

The PSR2 review of Safety Factor 2 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25 [3] and CNSC REGDOC-2.3.3 [2]:

   RT1) Assess and document present conditions of the SSCs important to safety and confirm appropriate measures to address any significant existing or anticipated aging degradation are in place. Any major difference between operating units with respect to aging degradation mechanisms, present condition, or recommended actions shall also be presented.

   RT2) Confirm resources and facilities (on and off site) are available for ongoing plant maintenance.

   RT3) After determining the actual condition of SSCs important to safety, each of these SSCs will be assessed against the current design basis to confirm that design basis assumptions have not been significantly challenged and will remain that way throughout the period of PSR2.

   RT4) Review the condition and operation of spent fuel storage facilities and their effect on the spent fuel storage strategy for Pickering NGS.

   RT5) Assess dependence on obsolescent equipment for which no direct substitute is available.

   RT6) Assess dependence on essential services and/or supplies external to the plant.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.

3. Reviewing the effectiveness of the following applicable OPG Nuclear Programs that support the above assessments, through a review of audit and self-assessment results. Nuclear Program effectiveness reviews associated with Safety Factor 2 are provided in the Safety Factor 4 Report [12], and a synopsis of effectiveness review results is provided in the Safety Factor 4 Report summary.

N-PROG-MP-0004	Pressure Boundary

The modern Laws, Regulations, Codes and Standards assessed in the review of this Safety Factor, along with the type of assessment conducted for each, are identified in Appendix A.

6.1.2.3. Summary and Conclusions

Table 4 lists the eighteen PSR2 Gaps identified in the Safety Factor 2 report [13], together with the source of each Gap and the associated Global Issue number.

The Safety Factor 2 report states that the assessment "has not identified any major concerns that the SSCs will continue to operate as per the design basis requirements during life extension" [13]. The report also notes the presence of comprehensive and effective programs in place to ensure the condition of components meets design requirements with margin.

6.1.3. SF3: Equipment Qualification (Environmental and Seismic)

6.1.3.1. Objective

The objective of the review of Safety Factor 3, Equipment Qualification (Environmental and Seismic), is to determine whether plant equipment important to safety has been properly qualified (including for environmental conditions) and whether this qualification is being maintained through an adequate program of maintenance, inspection and testing that provides confidence in the delivery of safety functions throughout the period of PSR2.

6.1.3.2. Scope of the Review

The PSR2 review of Safety Factor 3 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25 [3] and CNSC REGDOC-2.3.3 [2]:

    RT1) Confirm there exists a suite of engineering programs or processes to ensure equipment qualification requirements are met and documented.

    RT2) Confirm equipment qualification has been adequately established for all service conditions expected during normal operation, anticipated operational occurrences and accident conditions. These service conditions are subdivided into environmental conditions and operational conditions. Environmental conditions include ambient temperature, pressure, humidity/steam, radiation, water/chemical sprays, fluid submergence, fire and seismic vibration. Operational conditions include process related conditions such as vibration, load cycling, electrical loading parameters, electromagnetic interference, mechanical loads and process fluid condition.

    RT3) Perform an objective confirmation that the installed equipment is qualified to perform its Design Basis function for its operational life and that effective programs exist to monitor for timely maintenance or replacement, as required.

    RT4) Confirm existence of a process for ensuring compliance with equipment qualification programs and of documented previous qualification measures taken to ensure qualification throughout the equipment’s installed life (i.e., prescribed testing, calibration, maintenance, and parts replacement).

    RT5) Confirm existence of a surveillance program and a feedback procedure to ensure aging degradation of qualified equipment remains insignificant.

RT6) Confirm existence of monitoring of actual environmental conditions and identification of ‘hot spots’ of high activity or temperature.

RT7) Confirm existence of an assessment that determines the effects of equipment failures on equipment qualification and appropriate corrective actions and/or safety improvements to maintain equipment qualification.

RT8) Confirm there is protection and adequate separation of qualified equipment from adverse environmental conditions.

RT9) Confirm physical condition and functional capability of qualified equipment is being checked by walkdowns.

RT10) Confirm that changes to equipment classification have occurred, as required, as a result of major design modifications made since PSR1.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.
3. Reviewing the effectiveness of the following applicable OPG Nuclear Programs that support the above assessments, through a review of audit and self-assessment results[5].

Document Number	Document Title
N-PROG-RA-0006	Environmental Qualification
N-PROG-MP-0001	Engineering Change Control
N-PROG-MA-0004	Conduct of Maintenance
N-PROG-MP-0008	Integrated Aging Management
N-PROG-MP-0009	Design Management

The modern Laws, Regulations, Codes and Standards assessed in the review of this Safety Factor, along with the type of assessment conducted for each, are identified in Appendix A. The bases for the types of assessments performed are provided in Section 2.2 of the Safety Factor 3 Report [14].

[5] Although there may be content in Nuclear Programs that is applicable to multiple Safety Factors, each N-PROG review is only documented in one Safety Factor Report.

6.1.3.3. Summary and Conclusions

Table 5 lists the six PSR2 Gaps identified in the Safety Factor 3 report [14], together with the source of each Gap and the associated Global Issue number.

The Safety Factor 3 report states the review "has confirmed that the Pickering NGS equipment important to safety has been properly qualified and that this qualification is being maintained through an adequate program of maintenance, inspection and testing" [14].

6.1.4. SF4: Aging

6.1.4.1. Objective

The objective of the review of Safety Factor 4, Aging, is to determine whether aging aspects affecting SSCs important to safety are being effectively managed and whether an effective

[6] Each Gap ID# entry is hyperlinked to a description of the Gap and to the associated Global Issue in Appendix B.

aging management program is in place so that all required safety functions will be delivered throughout the period of PSR2.

6.1.4.2. Scope of the Review

The PSR2 review of Safety Factor 4 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25 [3] and CNSC REGDOC-2.3.3 [2]:

   RT1) Confirm there is a documented method and criteria for identifying safety related SSCs covered by the Aging Management Program.

   RT2) Ensure there is an effective Aging Management Program and dedicated organization with clearly defined roles and responsibilities with sufficient resources to continually assess aging effects in safety related SSCs.

   RT3) Establish a list of SSCs covered by the aging management program and records that provide information in support of the management of aging.

   RT4) Evaluate and document impact of potential aging degradation of safety-related SSCs.

   RT5) Confirm or develop understanding of dominant aging mechanisms of safety-related SSCs.

   RT6) Confirm existence of predictive maintenance program.

   RT7) Ensure existence of programs for timely detection and mitigation of aging mechanisms and/or aging effects of any SSCs important to safety, including obsolescence of technology used in the plant or obsolescence of services or supplies external to the plant.

   RT8) Establish acceptance criteria and required safety margin for safety-related SSCs for the period of PSR2 through reliability and risk assessments.

   RT9) Confirm adequacy of management of the effects of aging on those parts of the plant that will be required for safety when the reactor has ceased operation, for example the spent fuel storage facilities.

   RT10) Confirm the models used to predict the evolution and advancement of aging degradation are properly supported in accordance with current accepted practices pertaining to aging degradation.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.
3. Reviewing the effectiveness of the following applicable OPG Nuclear Programs that support the above assessments, through a review of audit and self-assessment results. Nuclear Program effectiveness reviews associated with Safety Factor 2, Actual Condition of SSCs Important to Safety, are also provided in the Safety Factor 4 Report.

The COP actions associated with Gap SF4-18 are listed in Table 12.

6.2. Safety Analysis

6.2.1. SF5: Deterministic Safety Analysis

6.2.1.1. Objective

The objective of the review of Safety Factor 5, Deterministic Safety Analysis, is to determine to what extent the existing deterministic safety analysis is complete and remains valid when the following aspects have been taken into account:

- The actual plant design, including all modifications of SSCs since the last update of the safety analysis report or PSR1.
- Current operating modes and fuel management.
- The actual condition of SSCs important to safety and their predicted state at the end of the period covered by PSR2.
- The use of modern, validated computer codes.
- Current deterministic methods.
- Current safety standards and knowledge (including research and development outcomes).
- The existence and adequacy of safety margins.

6.2.1.2. Scope of the Review

The PSR2 review of Safety Factor 5 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25 [3] and CNSC REGDOC-2.3.3 [2]:

   RT1) Confirm the existence of current deterministic safety analyses and the assumptions used to perform these analyses.

   RT2) Evaluate the documentation and processes for defining, implementing and maintaining the Safe Operating Envelope (SOE).

   RT3) Perform assessment of OPG's Deterministic Safety Analysis to determine if the postulated events, event sequences and event combinations covered by the existing analysis are sufficient when compared against those for a modern nuclear power plant in accordance with the methodology in CNSC REGDOC-2.4.1, Deterministic Safety Analysis [15].

   RT4) Review adequacy of the documented guidelines for Deterministic Safety Analysis.

   RT5) Evaluate the supporting analyses for design extension conditions to confirm that the arrangements aimed at preventing or mitigating severe core damage meet regulatory requirements.

   RT6) Confirm that the impact of equipment failures and human errors, as well as the adequacy of engineering and administrative measures to prevent and mitigate accidents, have been analyzed and documented.

   RT7) Confirm that the capabilities of the plant in its current state, and where relevant with account taken of planned safety improvements, have been demonstrated to be within regulatory requirements and expectations for both normal operation and accident conditions. In addition, confirm that plans are in place to ensure that forecast operational conditions of the plant will meet acceptance criteria for the design basis, including adequacy of safety margins, throughout the period of PSR2.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.
3. Reviewing the effectiveness of the following applicable OPG Nuclear Program that supports the above assessments, through a review of audit and self-assessment results.

Document Number	Document Title
N-PROG-MP-0014	Reactor Safety Program

The modern Laws, Regulations, Codes and Standards assessed in the review of this Safety Factor, along with the type of assessment conducted for each, are identified in Appendix A. The bases for the types of assessments performed are provided in Section 2.2 of the Safety Factor 5 Report [16].

6.2.1.3. Summary and Conclusions

Table 7 lists the seven PSR2 Gaps identified in the Safety Factor 5 report [16], together with the source of each Gap and the associated Global Issue number.

The Safety Factor 5 report states that the review "has confirmed that the deterministic safety analysis programs and procedures at OPG are comprehensive, resulting in a systematic and disciplined approach to identifying, prioritizing and addressing any safety analysis related issues" [16].

SF5-7			Additional Review Findings in Section 4.4 of Safety Factor 5 Report	GI-15

6.2.2. SF6: Probabilistic Safety Assessment

6.2.2.1. Objective

The objective of the review of Safety Factor 6, Probabilistic Safety Assessment (PSA), is to determine:

- The extent to which the existing PSA study remains valid as a representative model of the plant.
- Whether the results of the PSA show that the risks are sufficiently low and well balanced for all postulated initiating events and operational states.
- Whether the scope (which should include all operational states and identified internal and external hazards), methodologies and extent (i.e., Level 1, 2 or 3) of the PSA are in accordance with current national and international standards and good practices.
- Whether the existing scope and application of PSA are sufficient.

6.2.2.2. Scope of the Review

The PSR2 review of Safety Factor 6 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25 [3] and CNSC REGDOC-2.3.3 [2]:

   RT1) Confirm existence of a PSA and the assumptions used, the fault schedule, the representations of operator actions and common cause events, the modelled plant configuration and consistency with other aspects of the safety case.

RT2) Confirm existence of processes to assess the impact of changes in plant design, operation, and plant specific failure data and update the PSA to reflect the current plant status as required.

RT3) Confirm there are guidelines to account for operator actions, common cause events, cross-link effects, redundancy and diversity.

RT4) Confirm that the accident management programs for accident conditions (design basis accident conditions and design extension conditions) are consistent with PSA models and results.

RT5) Confirm that the results of the PSA show that risks are sufficiently low and well balanced for all postulated initiating events and operational states, and meet relevant probabilistic safety criteria.

RT6) Review the extent to which hazards are represented in the PSA to verify that omissions are based on site specific justifications and that these omissions do not weaken the overall risk assessment for the plant.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.
3. Reviewing the effectiveness of the following applicable OPG Nuclear Program that supports the above assessments, through a review of audit and self-assessment results[9].

Document Number	Document Title
N-PROG-RA-0016	Risk and Reliability Program

The modern Laws, Regulations, Codes and Standards assessed in the review of this Safety Factor, along with the type of assessment conducted for each, are identified in Appendix A. The bases for the types of assessments performed are provided in Section 2.2 of the Safety Factor 6 Report [17].

6.2.2.3. Summary and Conclusions

Table 8 lists the five PSR2 Gaps identified in the Safety Factor 6 report [17], together with the source of each Gap and the associated Global Issue number.

[9] Although there may be content in Nuclear Programs that is applicable to multiple Safety Factors, each N-PROG review is only documented in one Safety Factor Report.

The Safety Factor 6 report states that the review "has confirmed that the PSA programs and procedures at OPG are comprehensive, resulting in a systematic and disciplined approach to identifying, prioritizing and addressing any PSA-related issues" [17].

Table 8: PSR2 Gaps Identified for Safety Factor 6

Gap ID#[10]	Source of Gap			GI #
	Review Task	Modern Laws, Regulations, Codes and Standards	Other	
SF6-1	5			GI-27
SF6-2	5			GI-27
SF6-3	5			GI-30
SF6-4		CNSC REGDOC-2.4.2		GI-32
SF6-5		CNSC REGDOC-2.5.2		GI-44

6.2.3. SF7: Hazard Analysis

6.2.3.1. Objective

The objective of the review of Safety Factor 7, Hazard Analysis, is to determine the adequacy of protection of the NPP against internal and external hazards, with account taken of the plant design, site characteristics, the actual condition of the SSCs important to safety and their predicted state at the end of the period covered by PSR2, and current analytical methods, safety standards and knowledge.

6.2.3.2. Scope of the Review

The PSR2 review of Safety Factor 7 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

[10] Each Gap ID# entry is hyperlinked to a description of the Gap and to the associated Global Issue in Appendix B.

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25 [3] and CNSC REGDOC-2.3.3 [2]:

   RT1) Perform an assessment of the existing Deterministic and Probabilistic analyses to confirm existence of hazard analyses for hazards listed below. The following hazards are to be included in the assessment:

   (i) Internal Hazards: Fire, Pipe whip, Steam release, Toxic gas, Flooding, Missiles, Spray, Explosion.

   (ii) External Hazards: Changes in site characteristics, High winds (Tornado), Seismic, Toxic gas, Flooding, Extreme temperatures, Aircraft crash, Explosions.

   RT2) Confirm that the analyses and/or methods take into account the plant design and the condition of SSCs important to safety (both at present and predicted for the end of the period covered by PSR2).

   RT3) For each relevant hazard, verify, by means of current analytical techniques and data, that the frequency of occurrence and/or the consequences of the hazard are sufficiently low so that either no specific protective measures are necessary, or the preventive and mitigatory measures in place are adequate.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.

3. Reviewing the effectiveness of the following applicable OPG Nuclear Program that supports the above assessments, through a review of audit and self-assessment results[11].

Document Number	Document Title
N-PROG-RA-0012	Fire Protection

The modern Laws, Regulations, Codes and Standards assessed in the review of this Safety Factor, along with the type of assessment conducted for each, are identified in Appendix A. The bases for the types of assessments performed are provided in Section 2.2 of the Safety Factor 7 Report [18].

[11] Although there may be content in Nuclear Programs that is applicable to multiple Safety Factors, each N-PROG review is only documented in one Safety Factor Report.

6.2.3.3. Summary and Conclusions

Table 9 lists the PSR2 Gap identified in the Safety Factor 7 report [18], together with the source of the Gap and the associated Global Issue number.

The Safety Factor 7 report states that the review "has confirmed the adequacy of protection of Pickering NGS against internal and external hazards, with account taken of plant design (including confirmation that analyses/methods address the condition of SSCs important to safety), site characteristics, and current analytical methods, safety standards and knowledge" [18].

Table 9: PSR2 Gaps Identified for Safety Factor 7

Gap ID#[12]	Source of Gap			GI #
	Review Task	Modern Laws, Regulations, Codes and Standards	Other	
SF7-1	1			GI-25

6.3. Performance and Feedback from Operating Experience

6.3.1. SF8: Safety Performance

6.3.1.1. Objective

The objective of the review of Safety Factor 8, Safety Performance, is to determine whether the plant's safety performance indicators and records of operating experience, including the evaluation of root causes of plant events, indicate any need for safety improvements.

6.3.1.2. Scope of the Review

The PSR2 review of Safety Factor 8 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

[12] The Gap ID# entry is hyperlinked to a description of the Gap and to the associated Global Issue in Appendix B.

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25 [3] and CNSC REGDOC-2.3.3 [2]:

   RT1) Confirm existence of a system for identifying, classifying and recording safety related incidents and operating experience including:

   - Safety related incidents, low level events and near misses.
   - Safety related operational data.
   - Maintenance, inspection and testing.
   - Replacements of SSCs important to safety owing to failure or obsolescence.
   - Modifications, either temporary or permanent, to SSCs important to safety.
   - Unavailability of safety systems.
   - Radiation doses (to workers, including contractors).
   - Off-site contamination and radiation levels.
   - Discharges of radioactive effluents.
   - Generation of radioactive waste.

   RT2) Confirm that safety-related incidents are investigated using root cause analysis and that lessons learned from investigation of these incidents are fed back into the conduct of Operations and Maintenance.

   RT3) Confirm that the results of the root cause analysis are used to minimize the chances of the same incident reoccurring.

   RT4) Confirm that information from trend analysis of safety related incidents is fed back into the conduct of Operations and/or Maintenance.

   RT5) Confirm there is an adequate set of performance indicators that provides a systematic and comprehensive method to record, trend and analyze safety related data including the major system parameters, and maintenance and inspection records. Performance indicators may include:

   - Frequency of unplanned trips while the reactor is critical.
   - Satisfactory performance of safety system tests within required limits.
   - Special Safety System unavailability.
   - Reliability of Systems Important to Safety.
   - Collective annual radiation dose of plant staff.
   - Amount of gaseous and liquid radioactive release relative to permitted limits.
   - Heavy water escape and loss rates.

- Fuel reliability.
- Chemistry index.
- Volume of Low Level radioactive waste.
- Change control index.
- Maintenance backlog.
- Training.
- Environment Index.
- Non-radioactive effluents, including hazardous substances.
- Non-radioactive wastes.
- Spills.

RT6) Confirm that for cases where performance indicators show an unsatisfactory trend, corrective action is taken.

RT7) Review the adequacy of:

- Records of the integrity of physical barriers for the containment of radioactive material.
- Records of radiation doses to persons on the site.
- Records of data from off-site radiation monitoring and records of the quantities of radioactive effluents.
- Records of non-radioactive effluents, including hazardous substances.
- Records of radioactive and non-radioactive waste.
- Records of spills.
- Records of other environmental impacts.

RT8) Consider the effects of any changes in operation at the plant on safety performance. In particular, confirm that current indicators and other safety performance methods continue to be relevant in the context of current and future operations, and confirm that only relevant data and records are used.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.
3. Reviewing the effectiveness of the following applicable OPG Nuclear Programs that support the above assessments, through a review of audit and self-assessment results[13].

[13] Although there may be content in Nuclear Programs that is applicable to multiple Safety Factors, each N-PROG review is only documented in one Safety Factor Report.

Document Number	Document Title
N-PROG-RA-0002	Conduct of Regulatory Affairs
N-PROG-RA-0003	Corrective Action
OPG-PROG-0010	Health & Safety Management System Program

The modern Laws, Regulations, Codes and Standards assessed in the review of this Safety Factor, along with the type of assessment conducted for each, are identified in Appendix A. The bases for the types of assessments performed are provided in Section 2.2 of the Safety Factor 8 Report [19].

6.3.1.3. Summary and Conclusions

There were no PSR2 Gaps identified in the Safety Factor 8 Report [19].

The Safety Factor 8 report states that the review "has confirmed that the safety performance indicators and records of operating experience, including the evaluation of root causes of plant events, exist and are utilized to ensure the safe operation of Pickering NGS" [19].

6.3.2. SF9: Use of Experience from Other NPPs and Research Findings

6.3.2.1. Objective

The objective of the review of Safety Factor 9, Use of Experience from Other NPPs and Research Findings, is to determine whether there is adequate feedback of relevant experience from other NPPs and from the findings of research and whether this is used to introduce reasonable and practicable safety improvements at the plant or in the operating organization.

6.3.2.2. Scope of the Review

The PSR2 review of Safety Factor 9 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25 [3] and CNSC REGDOC-2.3.3 [2]:

   RT1) Confirm existence and adequacy of a program for the sending and receiving of experience relevant to safety to and from other nuclear power plants and relevant nonnuclear plants ("Other nuclear power plants" specifically include the IAEA, the Organization for Economic Cooperation and Development, Nuclear Energy Agency, the World Association of Nuclear Operators

(WANO), the Institute of Nuclear Power Operations (INPO) as well as CANDU Owners Group and experience within OPG at Darlington).

RT2) Confirm existence of a program for receiving information on the findings of relevant research programs.

RT3) Confirm there is a process for assessing the significance of operating experience from other plants and incorporating the lessons learned into improving safety performance at the station.

RT4) Confirm that there is a process for assessing the significance of research findings and technology developments and for incorporating relevant improvements into the station's design and operation.

RT5) Review adequacy and effectiveness of the feedback arrangements and timely implementation of assessment findings. (Assess program audit results).

RT6) List the major Operating Experience (OPEX) events and resulting plant changes that have resulted since PSR1 was completed.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.
3. Reviewing the effectiveness of applicable OPG Nuclear Programs that support the above assessments, through a review of audit and self-assessment results. There are no OPG Nuclear Programs assessed for the Use of Experience from Other NPPs and Research Findings in this report. Audit and self-assessment results for N-PROG-RA-0003, Corrective Action are provided in the Safety Factor 8 Report summary.

The modern Laws, Regulations, Codes and Standards assessed in the review of this Safety Factor, along with the type of assessment conducted for each, are identified in Appendix A. The bases for the types of assessments performed are provided in Section 2.2 of the Safety Factor 9 Report [20].

6.3.2.3. Summary and Conclusions

There were no PSR2 Gaps identified in the Safety Factor 9 Report [20].

The Safety Factor 9 report states that the review "has confirmed for Pickering NGS that there is adequate feedback of relevant experience from other nuclear power plants and from findings of research, and that this is used to introduce reasonable and practicable safety improvements at the plant or in the operating organization" [20].

6.4. Management

6.4.1. SF10: Organization, the Management System and Safety Culture

6.4.1.1. Objective

The objective of the review of Safety Factor 10, Organization, the Management System and Safety Culture, is to determine whether the organization, the management system and safety culture are adequate and effective for ensuring the safe operation of the plant.

6.4.1.2. Scope of the Review

The PSR2 review of Safety Factor 10 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25 [3] and CNSC REGDOC-2.3.3 [2]:

   RT1) Review organization and administrative procedures to ensure they play a significant role in defining safety culture and evaluate the adequacy of safety culture indicators.

   RT2) Establish existence of a safety policy to ensure that safety takes precedence over production where a conflict between these two requirements exists.

   RT3) Identify the method for setting performance targets and confirm that these targets are regularly and systematically reviewed. Confirm that appropriate actions are initiated if safety targets are not met.

   RT4) Confirm that the published Nuclear organization, including any recent changes made to the organization, clearly defines the roles and responsibilities of all individuals and work groups who are involved in activities that could influence the safe operation of the station. Ensure that this organization is understood and that adequate and effective procedures are in place to ensure the availability of these resources and to control changes to this organization.

   RT5) Establish that mechanisms for maintaining configuration control of the plant and its documentation are effective and up-to-date.

   RT6) Confirm that there are formal arrangements for employing external technical, maintenance or other specialist staff, and confirm that the contracting procedures ensure that contract employees are qualified to do the work assigned to them.

RT7) Confirm that there is an approved Quality Assurance program and that regular Quality Assurance audits are conducted involving both internal and independent assessors.

RT8) Confirm that a program for self-assessment and continuous improvement has been adequately and effectively implemented including feedback of experience relating to organizational and management failures.

RT9) Confirm there is a system to ensure that comprehensive, easily retrievable, and auditable records exist of baseline design information, and operational and maintenance history.

RT10) Confirm there is an effective framework in place to support the management of regulatory affairs.

RT11) Confirm that the organization and management system include the processes and supporting information that explain how work is to be specified, prepared, reviewed, performed, recorded, assessed and improved.

RT12) Confirm there is control of purchasing of equipment and services where this affects plant safety.

RT13) Confirm there are comprehensive communication policies in place.

RT14) Confirm that a questioning attitude exists and conservative decision making is undertaken in the organization.

RT15) Verify that there is a process in place for prioritization of safety issues, with realistic objectives and timescales that ensures that these issues receive proper resources.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.
3. Reviewing the effectiveness of the following applicable OPG Nuclear Programs that support the above assessments, through a review of audit and self-assessment results[14].

Document Number	Document Title
N-PROG-AS-0001	Managed Systems
N-PROG-AS-0002	Human Performance

[14] Although there may be content in Nuclear Programs that is applicable to multiple Safety Factors, each N-PROG review is only documented in one Safety Factor Report.

Document Number	Document Title
N-PROG-RA-0010	Independent Assessment

The modern Laws, Regulations, Codes and Standards assessed in the review of this Safety Factor, along with the type of assessment conducted for each, are identified in Appendix A. The bases for the types of assessments performed are provided in Section 2.2 of the Safety Factor 10 Report [21].

6.4.1.3. Summary and Conclusions

There were no PSR2 Gaps identified in the Safety Factor 10 Report [21].

The Safety Factor 10 report states that the review "has confirmed that the Pickering NGS organization, the management system and safety culture are adequate and effective for ensuring the safe operation of the plant" [21].

6.4.2. SF11: Procedures

6.4.2.1. Objective

The objective of the review of Safety Factor 11, Procedures, is to determine whether the operating organization's processes for managing, implementing and adhering to operating and working procedures and for maintaining compliance with operational limits and conditions and regulatory requirements are adequate and effective and ensure plant safety.

6.4.2.2. Scope of the Review

The PSR2 review of Safety Factor 11 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25 [3] and CNSC REGDOC-2.3.3 [2]:

   RT1) Determine if there is a process for the development, approval, and documenting of all safety related procedures.

   RT2) Confirm there is a formal process for modifying procedures affecting safety, including adequate arrangements for tracking changes.

   RT3) Confirm there is a program for assessing procedures and performance audits to determine if there is regular review and maintenance of these procedures.

RT4) Confirm that self-assessments are performed to ensure that the procedures are followed.

RT5) Establish that there is a means for assessing the adequacy of safety related procedures in comparison with industry good practices.

RT6) Confirm that there are operating procedures that apply comprehensively to normal, abnormal and emergency conditions (including anticipated operational occurrences, design basis accident conditions, post-accident conditions, and design extension conditions).

RT7) Confirm there is a means for assuring the clarity of procedures taking into account human factors.

RT8) Evaluate processes to update procedures to allow for changes in the assumptions made and/or the limits and conditions arising from the safety analysis, plant design and operating experience.

RT9) Verify that the analysis and justification of the accident management procedures are documented.

RT10) Verify that an appropriate process is in place for the categorization of procedures in accordance with their significance to safety.

RT11) Examine whether there is adequate involvement in the development of procedures by the staff that will use them.

RT12) Evaluate the distribution process for the control, copying and removal of obsolete versions of procedures, so that only the last approved edition is used.

RT13) Evaluate audits, self-assessments, safety performance and events to determine whether there is adequate understanding and acceptance of these procedures by managers and staff.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.
3. Reviewing the effectiveness of the following applicable OPG Nuclear Program that supports the above assessments, through a review of audit and self-assessment results[15].

[15] Although there may be content in Nuclear Programs that is applicable to multiple Safety Factors, each N-PROG review is only documented in one Safety Factor Report.

Document Number	Document Title
N-PROG-OP-0001	Nuclear Operations

The modern Laws, Regulations, Codes and Standards assessed in the review of this Safety Factor, along with the type of assessment conducted for each, are identified in Appendix A. The bases for the types of assessments performed are provided in Section 2.2 of the Safety Factor 11 Report [22].

6.4.2.3. Summary and Conclusions

There were no PSR2 Gaps identified in the Safety Factor 11 Report [22].

The Safety Factor 11 report states that the review "has confirmed that the Pickering NGS processes for managing, implementing and adhering to operating and working procedures and for maintaining compliance with operational limits and conditions and regulatory requirements are adequate and effective and ensure plant safety" [22].

6.4.3. SF12: Human Factors

6.4.3.1. Objective

The objective of the review of Safety Factor 12, Human Factors, is to evaluate the various human factors that may affect the safe operation of the NPP and to seek to identify improvements that are reasonable and practicable.

6.4.3.2. Scope of the Review

The PSR2 review of Safety Factor 12 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25 [3] and CNSC REGDOC-2.3.3 [2]:

    RT1) Confirm that there are procedures to ensure that a minimum number of qualified staff, appropriate to the operating state of the plant, is available at all times.

    RT2) Confirm that adequate staff training facilities, training staff and training programs exist.

RT3) Confirm that the method of selecting staff for new positions and for promotions involves systematic and validated staff selection methods and a method for succession planning.

RT4) Confirm that there are appropriate programs for initial, refresher, and upgrade training. For operating staff, this should include the use of simulators.

RT5) Establish that there is training in safety culture, including for management staff, that includes work supervision practices and internal communication practices and expectations.

RT6) Confirm there are fitness for duty guidelines relating to hours of work, health and substance abuse.

RT7) Confirm that the human–machine interface is considered in the design of the control room and other workstations, that analysis of human information requirements and task workload is performed, and that there is linkage to the Probabilistic Safety Assessment, Deterministic Safety Analysis and Hazard Analysis. This review should include a discussion of how guidance such as U.S. NRC NUREG-0700 Revision 2, Human-System Interface Design Review Guidelines and NUREG-0711 Revision 2, Human Factors Engineering Program Review Model, identified in CNSC REGDOC-2.5.2 are relevant to the design of Pickering Units 1,4 and 5-8 (Note: Review Task #7 is addressed in the Plant Design Safety Factor 1 Report).

RT8) Confirm the style and clarity of procedures provides an appropriate level of detailed guidance for staff through a review of plant events identifying inadequate procedures as a contributing cause.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.
3. Reviewing the effectiveness of the following applicable OPG Nuclear Program that supports the above assessments, through a review of audit and self-assessment results[16].

Document Number	Document Title
N-PROG-TR-0005	Training

The modern Laws, Regulations, Codes and Standards assessed in the review of this Safety Factor, along with the type of assessment conducted for each, are identified in Appendix A.

[16] Although there may be content in Nuclear Programs that is applicable to multiple Safety Factors, each N-PROG review is only documented in one Safety Factor Report.

The bases for the types of assessments performed are provided in Section 2.2 of the Safety Factor 12 Report [23].

6.4.3.3. Summary and Conclusions

There were no PSR2 Gaps identified in the Safety Factor 12 Report [23].

The Safety Factor 12 report states that the review "has confirmed that the various human factors that may affect the safe operation of Pickering NGS have been appropriately addressed" [23].

6.4.4. SF13: Emergency Planning

6.4.4.1. Objective

The objective of the review of Safety Factor 13, Emergency Planning, is to determine whether:

a) The operating organization has in place adequate plans, staff, facilities and equipment for dealing with emergencies.

b) The operating organization's arrangements have been adequately coordinated with the arrangements of local and national authorities and are regularly exercised.

6.4.4.2. Scope of the Review

The PSR2 review of Safety Factor 13 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25 [3] and CNSC REGDOC-2.3.3 [2]:

   RT1) Confirm the full range of accidents and radiation emergencies have been identified and studied.

   RT2) Confirm the appropriate response and mitigation strategies have been developed and have taken account of major changes at site and around the site (industrial, commercial, residential development).

   RT3) Confirm that the station organization includes dedicated Emergency Response personnel on duty at the plant at all times, to handle accidents and emergencies.

   RT4) Assess the adequacy of the training program for emergency response personnel including training, emergency exercises and qualification records.

RT5) Confirm there is a process for notification of staff that will be brought in to assist in the management of the response in the longer term.

RT6) Determine that there is a classification of accidents to guide the type of response.

RT7) Confirm there is a mechanism for notifying and informing relevant off-site organizations such as the police, fire departments, hospitals, ambulance services, regulatory bodies, local authorities, government, public welfare authorities and the news media.

RT8) Confirm the availability of sufficient communications equipment at the plant and at the off-site Emergency Centre to permit effective communications with Emergency Response Teams, both on and off site.

RT9) Assess adequacy of the emergency response procedures and training and exercises for all site staff. Confirm that integrated and partial emergency exercises have been conducted to check satisfactory function of the emergency organization and its equipment.

RT10) Confirm the adequacy of on-site equipment and facilities for emergencies and offsite emergency facilities or locations, including walkdowns of relevant areas on and off the site.

RT11) Confirm development or existence of a program for Severe Accident Management.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.
3. Reviewing the effectiveness of the following applicable OPG Nuclear Program that supports the above assessments, through a review of audit and self-assessment results[17].

Document Number	Document Title
N-PROG-RA-0001	Consolidated Nuclear Emergency Plan

The modern Laws, Regulations, Codes and Standards assessed in the review of this Safety Factor, along with the type of assessment conducted for each, are identified in Appendix A. The bases for the types of assessments performed are provided in Section 2.2 of the Safety Factor 13 Report [24].

[17] Although there may be content in Nuclear Programs that is applicable to multiple Safety Factors, each N-PROG review is only documented in one Safety Factor Report.

6.4.4.3. Summary and Conclusions

Table 10 lists the two PSR2 Gaps identified in the Safety Factor 13 report [24], together with the source of each Gap and the associated Global Issue number.

The Safety Factor 13 report states that the review "has confirmed that OPG Nuclear has: a) adequate plans, staff, facilities and equipment in place for dealing with emergencies, and b) there are adequate arrangements in place for regular emergency training and exercises, and interaction and coordination with local and national authorities" [24].

Table 10: PSR2 Gaps Identified for Safety Factor 13

Gap ID#[18]	Source of Gap			GI #
	Review Task	Modern Laws, Regulations, Codes and Standards	Other	
SF13-1		CNSC REGDOC-2.10.1		GI-41
SF13-2			Additional Review Findings in Section 4.4 of Safety Factor 13 Report	GI-26

6.5. Environment

6.5.1. SF14: Radiological Impact on the Environment

6.5.1.1. Objective

The objective of the review of Safety Factor 14, Radiological Impact on the Environment, is to determine whether the operating organization has an adequate and effective program for monitoring the radiological impact of the plant on the environment, which ensures that emissions are properly controlled and are As Low as Reasonably Achievable (ALARA).

[18] Each Gap ID# entry is hyperlinked to a description of the Gap and to the associated Global Issue in Appendix B.

6.5.1.2. Scope of the Review

The PSR2 review of Safety Factor 14 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25 [3] and CNSC REGDOC-2.3.3 [2]:

    RT1) Confirm there are procedures in place to ensure that permitted release limits of radiological substances are not exceeded and, if they are, that appropriate corrective action is taken to minimize the possibility of limits being exceeded in the future.

    RT2) Confirm records of radiological effluent release are maintained in accordance with regulatory requirements.

    RT3) Confirm that a program exists to define the requirements for alarm systems to respond to unplanned effluent releases from on-site facilities.

    RT4) Confirm the environmental data recorded by the station is published and is available on request to the general public.

    RT5) Review the environmental data recorded by the station and compare with the values measured before the plant was put into operation.

    RT6) Confirm there is a process to address changes in the use of land external to the site with respect to the impact on public safety from facility releases.

    RT7) Confirm that the monitoring program is appropriate and sufficiently comprehensive. In particular, confirm that the radiological impact of the plant on the environment is not significant compared with that due to other sources of radiation.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.

3. Reviewing the effectiveness of the following applicable OPG Nuclear Programs that support the above assessments, through a review of audit and self-assessment results[19].

Document Number	Document Title
N-PROG-OP-0006	Environmental Management

[19] Although there may be content in Nuclear Programs that is applicable to multiple Safety Factors, each N-PROG review is only documented in one Safety Factor Report.

Document Number	Document Title
OPG-PROG-0005	Environmental Management System

The modern Laws, Regulations, Codes and Standards assessed in the review of this Safety Factor, along with the type of assessment conducted for each, are identified in Appendix A. The bases for the types of assessments performed are provided in Section 2.2 of the Safety Factor 14 Report [25].

6.5.1.3. Summary and Conclusions

There were no PSR2 Gaps identified in the Safety Factor 14 Report [25].

The Safety Factor 14 report states that the review "has confirmed that Pickering NGS has an adequate and effective program for monitoring the radiological impact of the plant on the environment, which ensures that emissions are properly controlled and are as low as reasonably achievable" [25].

6.6. Radiation Protection

6.6.1. SF15: Radiation Protection

6.6.1.1. Objective

The objective of the review of Safety Factor 15, Radiation Protection, is to confirm that:

- Radiation Protection has been adequately accounted for in the design and operation of Pickering NGS.
- Radiation Protection provisions (including design and equipment) provide adequate protection of persons from the harmful effects of radiation.
- Contamination and radiation exposures and doses to persons are monitored and controlled, and maintained ALARA.

6.6.1.2. Scope of the Review

The PSR2 review of Safety Factor 15 contributes to confirming that the design, condition and operation of Pickering Units 1,4 and 5-8 (as well as common systems) will support continued safe operation for the period of PSR2 by:

1. Assessing compliance against the following Review Tasks identified in the PSR2 Basis Document [1], which were derived from IAEA SSG-25 [3] and CNSC REGDOC-2.3.3 [2]:

    RT1) Confirm the adequacy of the reactor design features for Radiation Protection.

RT2) Confirm the adequacy of the Radiation Protection equipment and instrumentation for radiation monitoring.

RT3) Confirm that adequate provisions are in place to address Radiation Protection of the public and workers during nuclear emergencies.

RT4) Confirm that the Radiation Protection provisions have been improved as the result of external operating experience.

RT5) The review will demonstrate that the ALARA principle has been incorporated in any modifications of the reactor design and operational programs and arrangements.

2. Documenting assessments against applicable modern Laws, Regulations, Codes and Standards defined in the PSR2 Basis Document [1], per Appendix A.
3. Reviewing the effectiveness of the following applicable OPG Nuclear Program that supports the above assessments, through a review of audit and self-assessment results[20].

Document Number	Document Title
N-PROG-RA-0013	Radiation Protection

The modern Laws, Regulations, Codes and Standards assessed in the review of this Safety Factor, along with the type of assessment conducted for each, are identified in Appendix A. The bases for the types of assessments performed are provided in Section 2.2 of the Safety Factor 15 Report [26].

6.6.1.3. Summary and Conclusions

There were no PSR2 Gaps identified in the Safety Factor 15 Report [26].

The Safety Factor 15 report states that the review "has confirmed that Radiation Protection has been adequately accounted for in the design and operation of Pickering NGS, and that Radiation Protection provisions (including design and equipment) provide adequate protection of persons from the harmful effects of radiation, and that contamination and radiation exposures and doses to persons are monitored and controlled and maintained ALARA" [26].

[20] Although there may be content in Nuclear Programs that is applicable to multiple Safety Factors, each N-PROG review is only documented in one Safety Factor Report.

7. Review of the Pickering B ISR Continued Operations Plan

7.1. Objective

The objective of the Pickering B ISR COP Review in support of PSR2 [5] was to reassess the 88 applicable actions from the Pickering B ISR COP referred to in [27] and documented in [28] that need to be reassessed for PSR2, based on extended operation beyond 2020. The 88 COP actions were also reviewed for applicability to Pickering 1,4.

7.2. Scope of the Review

The Pickering B ISR COP was developed to document the actions that helped support continued operation of Pickering Units 5-8. The COP planning basis was operation to 2020. The COP was updated annually from 2010 through to 2015. A final update was provided in December 2015 ([29], [30]).

Per the PSR2 Basis Document [1], the COP actions were reviewed based on assumed operation to the end of 2028. The COP actions were also reviewed for applicability to Pickering 1,4. This approach is consistent with Reference [31] in that it takes into account CNSC staff comments on the 2013 version of the COP, as this version included the most comprehensive COP action listing. The 88 applicable actions were addressed in the Pickering B ISR COP Review in support of PSR2 [5].

The applicable COP actions are assigned action codes beginning with “F”, “G” or “I”. As described in the COP [30], “F” actions are from Life Cycle Management Plans or Condition Assessments, “G” actions arose from the Pickering B Global Assessment and “I” actions originated in the Pickering B ISR.

7.3. Summary of Gaps

The COP Review identified twenty-six PSR2 Gaps. Table 11 identifies the Global Issue number associated with each PSR2 COP Review Gap. The Pickering B ISR Integrated Implementation Plan (IIP) identification numbers (ID) are also included for completeness.

Table 11: PSR2 Gaps from Review of the Pickering B Continued Operations Plan

COP Review Gap ID#[21]	GI #	Pickering B ISR IIP ID Number
COP-1	GI-1	F02-1a
COP-2	GI-4	F04
COP-3	GI-5	F05
COP-4	GI-43	F06
COP-5	GI-29	F07
COP-6	GI-29	F08
COP-7	GI-28	F09
COP-8	GI-2	F14-1b
COP-9	GI-3	F14-2a
COP-10	GI-4	F14-3a
COP-11	GI-4	F14-3b
COP-12	GI-4	F14-3c
COP-13	GI-4	F14-3d
COP-14	GI-31	G01-06
COP-15	GI-11	G02-01
COP-16	GI-19	G04-03
COP-17	GI-13	I02
COP-18	GI-46	I03-1
COP-19	GI-23	I04

[21] Each Gap ID# entry is hyperlinked to a description of the Gap and to the associated Global Issue in Appendix B.

COP Review Gap ID#[21]	GI #	Pickering B ISR IIP ID Number
COP-20	GI-25	I09
COP-21	GI-31	I10, I10-01
COP-22	GI-5	I15-1d
COP-23	GI-21	I15-5d
COP-24	GI-49	I15-5e
COP-25	GI-19/GI-43	I15-6b
COP-26	GI-4	I15-7b

In the Pickering NGS PSR2 Safety Factor 4 Report [12], COP actions were also evaluated for applicability to PSR2. Two Gaps were identified. For completeness, the information on the related PSR2 Gaps is repeated below.

- PSR2 Gap SF4-13: Actions #31, #32, and #33 from the Pickering Units 5-8 Continued Operations Plan are related to N287.7 and although complete, need to be re-assessed for Pickering operation beyond 2020. (IIP Action #31 involved submission of Periodic Inspection Programs (PIPs) and Life Cycle Management Plans (LCMPs) for a number of safety-significant civil structures. IIP Action #32 involved submission of Aging Management Plans for Concrete Containment Structures to the CNSC for acceptance. IIP Action #33 involved revising the Reactor Building PIP and submitting to the CNSC for acceptance).
- PSR2 Gap SF4-18: Review of the Pickering Units 5-8 Continued Operations Plan identified the closed gaps from the Pickering B ISR outlined in Table 12 that will need to be revisited in the context of continued operation past 2020. The items included in SF4-18 are associated with Global Issue GI-22.

Table 12: Elements of PSR2 Gap SF4-18 – Global Issue GI-22

ID # from the COP ([29], [30])	Pickering B ISR IIP ID Number
Appendix A Item 4	G01-04
Appendix A Items 10, 11, 12, 13	F01 (including F01-1, F01-2, F01-3, F01-4)

ID # from the COP ([29], [30])	Pickering B ISR IIP ID Number
Appendix A Item 14	F02
Appendix A Item 19	F13
Appendix A Item 21	F14-1a
Appendix A Item 30	F14-4.1
Appendix A Item 52	I15-1a
Appendix A Item 69	I15-7a
Appendix C Item 5	F11
Appendix C Item 6	F12

7.4. Conclusions

Actions identified in the Pickering Units 5-8 COP were reviewed for PSR2 in the context of Pickering NGS operation beyond 2020 [5]. Twenty-six Gaps were identified for consideration in the PSR2 Global Assessment, in addition to 10 items from the Pickering B ISR that were identified for re-assessment as part of Gap SF4-18 during the review of Safety Factor 4.

8. Review of Fukushima Action Items

8.1. Objective

A review of FAIs in support of PSR2 was performed to consider the impact of extended operation on all FAIs assigned to OPG that are applicable to Pickering NGS. The PSR2 Basis Document [1] states that FAIs will be reviewed to determine if there are any impacts associated with operation past 2020. This is consistent with CNSC staff feedback in [31] that OPG should consider the FAIs that were closed on the basis that Pickering NGS units were to shut down in 2020 and determine if the basis of closure is affected by the potential to operate Pickering NGS beyond 2020.

The FAIs were originally identified in [32]. The status of all FAIs for OPG facilities was summarized in OPG's Fukushima Action Item Status Report [33]. As noted in [33], OPG has completed, and the CNSC has closed, all FAIs assigned to OPG.

8.2. Scope of the Review

The scope of the review of FAIs in support of PSR2 considered all FAIs that were listed in [32] and the follow-up actions that were created to monitor progress related to specific issues. The assessment considered Pickering Units 1,4 and 5-8. Common systems (Unit 0) are included in the Unit assessments as applicable.

8.3. Summary of Gaps

There were no PSR2 Gaps identified from a review of the FAIs [6].

8.4. Conclusions

All FAIs in [32] were assessed for the impact of operation beyond 2020 on Pickering Units 1,4 and 5-8. It was concluded that none of the FAIs are impacted by extended operation of Pickering NGS beyond 2020.

OPG's responses to the FAIs assigned to Pickering NGS remain valid in the context of extended operation beyond 2020. There are no additional Gaps identified from a review of the FAIs that must be considered in the PSR2 Global Assessment.

9. Findings from CNSC Staff Reviews of Safety Factor Reports and Complementary Reviews

The OPG-CNSC Protocol for the conduct of PSR2 is described in [4] and includes the agreed upon strategy and schedule for PSR2, including submission of the PSR2 deliverables to CNSC staff for review. This section describes CNSC staff findings from their independent reviews of PSR2 documents that are inputs to the Global Assessment Report, and describes how these findings have been incorporated into the Global Assessment Report.

From the CNSC staff review of the 15 Safety Factor Reports and two Complementary Reviews (COP and FAI reviews), 75 Additional Gaps were identified [34] to [43].

As stated in the CNSC review reports [34] to [43], CNSC staff were guided and informed by the following in performing their reviews:

- The Nuclear Safety and Control Act [44]
- General Nuclear Safety and Control Regulations [45]
- CNSC REGDOC-2.3.3, Periodic Safety Reviews [2]
- PSR2 Basis Document [1]

CNSC staff also used additional regulatory documents, standards and expert judgment to perform their assessments. In total, CNSC staff identified 2 Strengths during their assessments of the Safety Factor Reports. The Strengths identified by CNSC staff are listed in Table 13. These Strengths were considered in the Defence-in-Depth Assessment (refer to Section 18).

Table 13: Strengths Based on CNSC Staff Reviews

Safety Factor	Strength Title and Description	Reference
SF9	On page 18, Section 4.1.1, OPG discussion on and the extent of coverage of “Receiving OPEX” is considered by CNSC staff as a strength.	[40]
SF11	On page 8, Section 2.1, OPG discussion on and the extent of coverage of “Review Task Assessments” is considered by CNSC staff as a strength.	[40]

Based on correspondence documented in References [34] to [43], the identified Additional Gaps are primarily requests for additional information, or for additional supporting evidence to support statements made by OPG in the Safety Factor Reports or Complementary Reviews. The Additional Gaps have been grouped into three types as follows:

Type I. Provision of information. These are Additional Gaps related to CNSC staff requests for additional supporting evidence for statements made by OPG in the Safety Factor and Complementary Review Reports.

Type II. Provision of additional information to demonstrate the effectiveness of OPG Programs. These are Additional Gaps related to CNSC staff requests for additional evidence of program effectiveness or follow-up on specific requests for evidence of conformance.

Type III. Specific technical issues. These are Additional Gaps related to CNSC staff identification of technical concerns, or demonstration of adequacy of implementation/response to issues of concern to CNSC staff.

As documented in [46], OPG committed to address each of the Type I and II Additional Gaps by March 15, 2018. The PSR2 Database that is currently being developed by OPG will be used to assist with tracking the status and progress to completion of these Additional Gaps.

The Type III Additional Gaps are consolidated with other related PSR2 Gaps into appropriate Global Issues. Each Global Issue is prioritized and, depending on the prioritization, proposed Resolution Statements may or may not be developed, consistent with the process for developing proposed Resolution Plans described in Section 5.4. If proposed Resolution Statements are developed for Type III Additional Gaps, the Resolution Statements are ranked.

The Type III Additional Gaps are listed in Table 14, together with the source of each Additional Gap and the associated Global Issue number in Appendix B. The naming convention used in Table 14 for the Additional Gaps is:

- SF#-AG#, for Gaps based on correspondence related to the Safety Factor Reports
- COP-AG#, for Gaps based on correspondence related to the COP
- FAI-AG#, for Gaps based on correspondence related to FAIs

Table 14: List of Additional Gaps Identified Based on CNSC Staff Reviews

Appendix
Appendix B – Global Issues and Proposed Resolution Plans
Appendix C – Ranking of Proposed Resolution Statements

10. Integrated Review of PSR2 Gaps

The elements of the Global Assessment process are described in Section 3.3.2 of the PSR2 Basis Document [1]. This section presents the results of completing the first step, which is a review and consolidation of the PSR2 Gaps. This step is a precursor to the identification of Global Issues.

PSR2 Gaps are identified from a review of the following sources, based on the guidance provided in Section 5.1:

- the Safety Factor Reports (93 Gaps identified in Sections 6.1.1 through 6.6.1, including 10 items from the Pickering B ISR (refer to Table 12) that were identified for re-assessment as part of Gap SF4-18 during the review of Safety Factor 4);
- the Complementary Review of the Pickering B ISR COP (26 Gaps identified in Section 7.3);
- the Complementary Review of the FAIs (no Gaps identified in Section 8.3); and
- CNSC Staff reviews of PSR2 deliverables (23 Additional Gaps identified in Section 9 for consideration in the Global Assessment).

A total of 142 PSR2 Gaps identified from the various sources are presented in Section 6 to Section 9, and one more Gap identified by the Expert Panel is presented in Section 15.5. The Gaps are grouped into Global Issues, as described in Section 11.

11. Development of Global Issues

The second element of the Global Assessment process (Section 3.3.2 of [1]) is the definition of Global Issues. Each Global Issue is derived from the grouped PSR2 Gaps described in Section 10.

There are two aspects to this step, as follows:

- Development of a Global Issue title and a description of the issue based on the related PSR2 Gaps; and
- Assessment of the interfaces between the various Safety Factors and the aggregate impact of Global Issues

This step follows the guidance provided in Section 5.2, using the Gaps listed in Section 6 to Section 9 and Section 15 as input.

11.1. Consolidation of Gaps into Global Issues

The Gaps listed in Section 6 to Section 9 and Section 15 are grouped into Global Issues in Appendix B according to their topical similarities, i.e., based on the related discipline, governing process or relevant modern codes and standards, with consideration of any interfaces, overlaps and similarities among the Gaps.

A total of 51 Global Issues are identified for the Pickering NGS PSR2. All 143 of the Gaps identified in Section 6 to Section 9 and Section 15 are mapped to one or more of the 51 Global Issues.

The Global Issue Titles are listed in Table 15. Full descriptions of each Global Issue are provided in Global Issue Tables in Appendix B, under the following section headings within each table:

Section 1 – Global Issue Summary

Section 2 – Associated Gaps

Section 3 – Background Information and Resolution Strategy

Section 4 – Priority Determination

Section 5 – Resolution Plan

The Safety Significance Level shown for each Global Issue in Table 15 is described in Section 12.

Table 15: PSR2 Global Issues

11.2. Assessment of Interfaces Between the Various Safety Factors and Aggregate Impact of Global Issues

Following the consolidation of PSR2 Gaps into Global Issues (refer to Section 11.1), which is based on topical similarities between PSR2 Gaps, a further review of the Global Issues was performed to confirm that the interfaces between Safety Factors are appropriately considered in the development of the Global Issues.

The result of the aggregate assessment of Global Issues is presented in Table 16. The table shows that for a given functional topic comprising more than one Global Issue, there are no interfaces or aggregate effects that warrant a change to Global Issue descriptions or proposed Resolution Plans. Rather, in many cases the table identifies that OPG programs in place will ensure a consistent approach to the resolution of Global Issues on the same functional topic, and that lessons learned from the execution of proposed Resolution Plans will be applied to the resolution of other Global Issues within the same group. In addition, in some cases proposed Resolution Plans already cross-reference those for related Global Issues, indicating that interfaces are already explicitly considered. In other cases, Global Issues within a group are distinct and unrelated, again resulting in no aggregate effect or need to modify proposed Resolution Plans.

It is noted that many of the Global Issues are related to fitness for service and aging management of SSCs. This is fully expected and does not indicate an additional aggregate effect. Condition Assessment and aging management of SSCs is recognized by OPG as one of the key issues for Pickering NGS. Work is actively underway to update Condition Assessments and confirm assurance of fitness for service for safety-related SSCs for the extended operating period. Much of this work is already complete for 2024.

In summary, OPG's integrated management system provides a framework to ensure a consistent approach and sharing of lessons learned for Global Issues on the same functional topic, even those that originate from different Safety Factors or other sources. It is concluded that interfaces and aggregate effects of Global Issues do not result in a need to modify Global Issue descriptions or proposed Resolution Plans.

Table 16: Aggregate Impact of Global Issues

Aggregate Topic	GI #	Global Issue Title	Source of Gaps	Aggregate Assessment
Fitness for Service	GI-1	Fitness for Service for Fuel Channels	SF2, SF4, COP	For the purposes of assessing the aggregate impacts of Global Issues, the Global Issues related to fitness for service of SSCs are considered together as one aggregate. Nineteen Global Issues related to fitness for service are included in this group. Fourteen of these Global Issues are comprised of Gaps associated with Safety Factors SF1, SF2 and SF4, which are all related to "The Plant" Safety Factor Subject Area, as well as COP Review actions. Four Global Issues are comprised of COP Review actions, and one Global Issue is comprised of an Expert Panel Gap. Of the 19 Global Issues in this group, five are related to Major Components, i.e., Fuel Channels, Feeders, Steam Generators and Reactor Components and Structures. The remaining Global Issues are related to other safety related SSCs. Although these Global Issues are related to different SSCs, their proposed Resolution Plans include cross-references to other Global Issue proposed Resolution Statements, such as updating of Condition Assessments or Life Cycle Management Plans, to address interfaces where appropriate. OPG has a well-developed and effectively implemented program for continued validation of fitness for service of the Major Components, and has completed a significant amount of work related to Condition Assessments of SSCs for the extended operating period. Work is actively underway to complete Condition Assessments and confirm fitness for service for safety-related SSCs for the extended operating period. The proposed Resolution Plan actions related to fitness for service will all be completed under the umbrella of N-PROG-MA-0026, *Equipment Reliability* [47] which interfaces with N-PROG-MP-0008,
	GI-2	Fitness for Service for Feeders	SF2, COP	
	GI-3	Fitness for Service for Steam Generators	SF2, COP	
	GI-4	Fitness for Service for Reactor Components and Structures	SF2, COP	
	GI-5	Completeness of Class 1 Piping / Components Service Limits Assessment (Excluding Major Components)	SF2, COP	
	GI-6	Impact of the Revised Criticality Coding on the Cable Surveillance Program	SF2	
	GI-7	Pickering Buried Piping Fitness for the Extended Operating Period	SF1, SF2	
	GI-8	Completion / Updating of the Condition Assessments	SF2	
	GI-10	IFB Condition	SF2, SF4	
	GI-17	FFS of Fiberglass Reinforced Plastic Material for the Extended Operating Period	SF4	
	GI-19	FFS of Containment for	SF4, COP	

Aggregate Topic	GI #	Global Issue Title	Source of Gaps	Aggregate Assessment
		the Extended Operating Period		*Integrated Aging Management* [48] and N-PROG-MA-0025, *Major Components* [49] for life cycle management planning, to ensure a consistent approach and to facilitate valuable sharing of information so that lessons learned can be effectively implemented. In addition, N-CHAR-AS-0002, *Nuclear Management System* [50] provides an effective mechanism to drive excellence in fitness for service of SSCs. Therefore, the interfaces among and the aggregate impact of the Global Issues in this group are fully addressed, and no additional impacts need to be considered.
	GI-21	FFS of the Deaerator and the Deaerator Storage Tank for the Extended Operating Period	COP	
	GI-22	COP Actions Related to Aging Management from SFR4	SF4, SF2	
	GI-28	Reactivity Worth of Control Absorbers	COP	
	GI-29	FFS of the Fuelling Machines and FM Bridge Ball Screws for the Extended Operating Period	COP	
	GI-33	N285.0-12, General Requirements for Pressure-Retaining Systems and Components in CANDU Nuclear Power Plants	SF1	
	GI-43	Safety-Related Structures (Non-Containment) for Nuclear Power Plants	SF1, SF2, SF4, COP	
	GI-49	FFS of PHT Auxiliary Piping Systems, and PHT Valves	COP	
	GI-51	Fuelling with Pressure Tube Sag	Expert Panel	

Aggregate Topic	GI #	Global Issue Title	Source of Gaps	Aggregate Assessment
Seismic Capacity	GI-9	Seismic Capacity of the Conveyor Tube and Fuel Basket Stacking Arrangement	SF2	This aggregate is comprised of two seismic related Global Issues. GI-9 is comprised of SF2 Gaps related to the seismic capacity of SSCs and GI-13 is comprised of SF3 Gaps and COP Review actions related to seismic qualification requirements. These Global Issues are unrelated. In addition, N-PROG-MP-0009, *Design Management* [51] is comprised of a series of engineering programs and procedures to ensure the adequacy of seismic qualification of SSCs [52]. Therefore, there is no additional aggregate impact.
	GI-13	Seismic Qualification - N289	SF3, COP	
Fuel Management	GI-11	Fuel Management and Surveillance Software Upgrade	COP	There is only one Global Issue related to fuel management and surveillance software, and therefore there is no additional aggregate impact.
Environmental Qualification	GI-12	Extending the Environmental Qualification of Equipment	SF3	There are two Global Issues, GI-12 and GI-14, related to environmental qualification of equipment that are considered as a group for the purposes of assessing the aggregate impact of Global Issues. These Global Issues are comprised of SF3 Gaps. Although these Global Issues pertain to separate Environmental Qualification issues, the work to address both of these issues will be governed by OPG's well-developed Environmental Qualification Program, N-PROG-RA-0006, *Environmental Qualification* [53], thus ensuring consistent updates of the relevant Environmental Qualification Assessment (EQA) documentation. Therefore, the aggregate impact of this group of Global Issues is fully addressed, and no additional impacts need to be considered.
	GI-14	Environmental Qualification Program Issues	SF3	
Conformance with modern Codes and Standards	GI-16	Concession Related to N285.5-M90	SF4	For the purposes of assessing the aggregate impact of Global Issues, 8 Global Issues related to conformance with safety-significant requirements of modern codes and standards are grouped together under this aggregate. There are other Global
	GI-23	ASME N509-1980	COP	

Aggregate Topic	GI #	Global Issue Title	Source of Gaps	Aggregate Assessment
		and N510-1980 – Air Cleaning Systems		Issues which pertain to modern codes and standards; however their aggregate impact is assessed in other groups according to the affected SSCs. The Global Issues in this group are comprised primarily of SF1, SF2 and SF4 Gaps, as well as SF5 and SF6 Gaps related to safety analysis, and COP Review actions. Although this group contains several Global Issues, the Global Issues are, for the most part, associated with separate and unrelated modern codes and standards or unrelated SSCs. OPG has well-developed and effectively implemented programs to ensure that the conditions of the Power Reactor Operating Licence are met. For the modern codes and standards that are not mandatory requirements of the licence or the Licence Conditions Handbook, the proposed Resolution Plans developed for the Global Issues ensure that appropriate actions are defined, or existing conditions (current practices, etc.) are adequately dispositioned. Therefore, there is no additional aggregate impact as a result of this group of Global Issues.
	GI-34	CSA N290.1-13 - Requirements for the Shutdown Systems	SF1	
	GI-36	CSA N290.2 – Requirements for Emergency Core Cooling Systems	SF1	
	GI-38	CSA N290.11 - Requirements for Reactor Heat Sinks	SF1	
	GI-39	CSA N290.14 - Qualification of Digital Hardware and Software for Use in I&C Applications	SF1	
	GI-44	REGDOC-2.5.2 - Design of Reactor Facilities: Nuclear Power Plants	SF1, SF5, SF6	
	GI-50	N285.4 PIP / Documentation Revision	SF2, SF4	
Governance Issues / Governance Implementation / Effectiveness	GI-15	Governance Issues	SF1, SF4, SF5	Two Global Issues related to governance issues or governance implementation and effectiveness, GI-15 and GI-20, are grouped together. The majority of Gaps associated with these Global Issues either require no further action or are assessed to be Acceptable Deviations. The Gaps are largely unrelated, and therefore there is no additional aggregate impact as a result of this group of Global Issues.
	GI-20	Governance Implementation / Effectiveness Issues	SF4	
Requirements for Containment	GI-18	N287.7 – In-Service Examination and Testing Requirements for	SF4	Two Global Issues related to requirements for Concrete Containment Structures, GI-18 and GI-42, are considered together as an aggregate. These Global Issues are

Aggregate Topic	GI #	Global Issue Title	Source of Gaps	Aggregate Assessment
		Concrete Containment Structures		comprised of SF1 and SF4 Gaps. The Gaps associated with GI-18 and GI-42 are not directly related. GI-18 relates to the requirements of CSA N287.7, "In-service Examination and Testing Requirements for Concrete Containment Structures for CANDU Nuclear Power Plants", which is applicable to the operations phase. GI-42 relates to the requirements of CSA N287.5 "Examination and Testing Requirements for Concrete Containment Structures for Nuclear Power Plants", which is applicable to the design and construction phase. The proposed Resolution Plans for these Global Issues either require no further action or are assessed as Acceptable Deviations. Therefore, there is no aggregate impact for these Global Issues.
	GI-42	Examination and Testing Requirements for Design of Concrete Containment Structures	SF1	
Deterministic Safety Analysis	GI-24	Safety Analysis to Support the Extended Operating Period	SF5, COP	Three Global Issues, GI-24, GI-25 and GI-31, are considered as an aggregate related to deterministic safety analysis. Although GI-24 is also related to fitness for service, it is considered as part of this aggregate as it is mainly related to the impact of aging components on the safety analysis. Some of the Gaps associated with GI-25 and GI-31 are related to SF1, Plant Design, but they pertain to safety analysis issues. This aggregate contains only three Global Issues, and the issues are not related; GI-24 is related to the impact of aging components on the safety analysis, GI-25 is related to re-categorization of CANDU safety issues from Category 3 to Category 2, and GI-31 is related to the implementation of REGDOC-2.4.1 on deterministic safety analysis. Therefore, there is no additional aggregate impact.
	GI-25	Category 3 CANDU Safety Issues	SF1, SF5, SF7, COP	
	GI-31	Deterministic Safety Analysis	SF1, SF5, COP	
Emergency Preparedness / Response	GI-26	Emergency Response Projection Software	SF13	There are two Global Issues, GI-26 and GI-41, related to Emergency Preparedness / Emergency Response. These Global Issues are comprised of SF13 Gaps which are related to the "Management" Safety Factor Subject Area. Although both Global Issues are concerned
	GI-41	REGDOC-2.10.1 - Nuclear Emergency	SF13	

Aggregate Topic	GI #	Global Issue Title	Source of Gaps	Aggregate Assessment
		Preparedness and Response		with emergency preparedness and emergency response, the associated Gaps are not related. Therefore, there is no additional aggregate impact.
Probabilistic Safety Assessment	GI-27	Pickering 1,4 Probabilistic Safety Assessment	SF1, SF6, FAI	Three Global Issues, GI-27, GI-30 and GI-32 are related to Probabilistic Safety Assessment. In addition, GI-37 and GI-40, which are each comprised of one SF1 Gap and one SF1 Additional Gap, are considered in relation to PSA for aggregation purposes since they are related to proposed risk improvement initiatives and Phase 2 of the Emergency Mitigating Equipment (EME) Project. Gap SF6-5 associated with GI-44 is related to requirements for PSA risk limits, such as a Core Damage Frequency limit of less than 10^{-5}/y. Gap SF6-5 is assessed as an Acceptable Deviation. GI-44 is related to conformance with REGDOC-2.5.2, *Design of Reactor Facilities: Nuclear Power Plants*, and is therefore grouped under the aggregate associated with conformance with modern codes and standards. The Gaps associated with these Global Issues are from SF1, SF6 and the FAI Review. The Gaps associated with GI-30 and GI-32 are stand-alone Gaps that are not related to each other or to other Gaps in this group. PSA activities are governed by OPG's Risk and Reliability Program [54], which ensures that the reliability of systems important to nuclear safety meets requirements and that PSA risk goals are met. The resolutions of GI-27, GI-37 and GI-40 are synergistic in that in aggregate, they enhance Containment integrity for Beyond Design Basis Accidents. The specific cross references are GI-27-XRF-GI-40-RS1, GI-37-XRF-GI-40-RS1 and GI-40-XRF-GI-27-RS2. In summary, any aggregate impacts are already accounted for in the proposed Resolution Plans for these Global Issues
	GI-30	Evaluation of Instantaneous Risk	SF6	
	GI-32	Implementation of REGDOC-2.4.2 PSA Requirements	SF6	
	GI-37	N290.3-11 - Requirements for Containment System	SF1	
	GI-40	Accident Management	SF1	

Aggregate Topic	GI #	Global Issue Title	Source of Gaps	Aggregate Assessment
				and there is no additional aggregate impact.
Human Factors	GI-35	Human Factors Issues	SF1	There is one SF1 Gap associated with this Global Issue. There are no other Global Issues related specifically to Human Factors, and therefore, there is no additional aggregate impact.
Fire Protection	GI-45	CRN Concession for Fire Protection Components	SF1	There are four Global Issues related to fire protection, GI-45, GI-46, GI-47 and GI-48. These Global Issues are comprised of SF1 Gaps, except for GI-46 which is comprised of a COP Review action. OPG has a comprehensive Fire Protection Program, N-PROG-RA-0012, *Fire Protection* [55] that is based on the requirements of CSA N293, *Fire Protection for CANDU Nuclear Power Plants*, the National Fire Code of Canada and NFPA 24, and other applicable codes and standards. The Global Issues in this group are related to conformance with these fire codes and standards but are distinct issues. Therefore, this group of Global Issues has no additional aggregate impact.
	GI-46	Requirements of National Fire Code of Canada for Units 1 & 4 Standby Generator Fuel Tanks	COP	
	GI-47	Fire Protection Code NFPA 24	SF1	
	GI-48	CSA N293-12 Fire Protection of Nuclear Power Plants	SF1	

12. Prioritization of Global Issues

The PSR2 Global Issues are prioritized with respect to their overall impact on enhancing nuclear safety, using the process outlined in Section 5.3. This step is the fourth element of the Global Assessment process, as described in Section 3.3.2 of the PSR2 Basis Document [1].

As described in Section 5.3, the basis for prioritization of each Global Issue is provided in Appendices E and F of the PSR2 Basis Document [1], and comprises Deterministic and Probabilistic considerations.

The Deterministic considerations are:

- Defence in Depth (E1)
- Safety Significance Levels (E2)

Using the guidelines provided in Appendix E of the PSR2 Basis Document [1], a Safety Significance Level of 1, 2, 3 or 4 is assigned to each Deterministic consideration based on whether the Global Issue has a high, medium, low or very low impact on nuclear safety for the consideration being evaluated. A Safety Significance Level of 1, 2, 3 or 4 is then assigned to the overall Deterministic consideration based on the most safety significant result. For Deterministic considerations that are not relevant to the Global Issue, the prioritization is recorded as “N/A” or “Not Applicable”.

There are 7 Probabilistic considerations, as follows:

- Reactor Safety Core Damage Frequency (F1)
- Reactor Safety Defence in Depth (F2)
- Public Radiation Safety (F3)
- Plant Operability (F4)
- Occupational Radiation Safety (F5)
- Emergency Preparedness (F6)
- Environment (F7)

Using the guidelines provided in Appendix F of the PSR2 Basis Document [1], a Safety Significance Level of 1, 2, 3 or 4 is assigned to each Probabilistic consideration based on whether the Global Issue has a high, medium, low or very low impact on nuclear safety for the consideration being evaluated. A Safety Significance Level of 1, 2, 3 or 4 is then assigned to the overall Probabilistic consideration based on the most safety significant result. For Probabilistic considerations that are not relevant to the Global Issue, the prioritization is recorded as “N/A” or “Not Applicable”.

The overall Safety Significance Level for the Global Issue is then assigned based on the Safety Significance Level of whichever overall consideration, Deterministic or Probabilistic, has the highest nuclear safety impact.

The results of the prioritization of the Global Issues, including the Safety Significance Level assigned to each Global Issue and the accompanying rationale, are provided in Section 4 of each Global Issue Table in Appendix B, using the prioritization template shown below.

SECTION 4 – GLOBAL ISSUE PRIORITY DETERMINATION												
Safety Significance of Global Issue	**Deterministic Considerations**			**Probabilistic Considerations**								**Overall Safety Significance Level**
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
<u>Rationale:</u> {This part of the prioritization template presents a brief description of the Global Issue and describes the impact of the Global Issue on each of the individual Deterministic and Probabilistic considerations, as well as the impact on the overall considerations. The overall Safety Significance Level is also summarized.}												

The results of the prioritization of the Global Issues are shown in Table 15 and summarized below.

Three of the 51 Global Issues are assessed as having a high impact on nuclear safety and are accordingly assigned Safety Significance Level 1. These are Global Issues GI-1, GI-2 and GI-3, which are all related to fitness for service of Major Components for the extended operating period. Their proposed Resolution Plans are considered the most important in terms of supporting the safe operation of Pickering NGS for the extended operation period. The Gaps associated with these Global Issues are related to Safety Factor 2 and Safety Factor 4, as well as actions from the COP. OPG was already fully aware of the need to complete work related to demonstration of fitness for service over the extended operating period, and is actively working on addressing the remaining work in this area to cover the extended operating period.

Nine Global Issues are assessed as having a medium impact on nuclear safety, and as such are assigned Safety Significance Level 2. These Global Issues are related to aging management (GI-22), safety analysis (GI-24), and fitness for service of Reactor Structures (GI-

4) and SSCs other than Major Components (GI-5, GI-8, GI-17, GI-19, GI-29 and GI-49). Resolution of these Global Issues will support the safe operation of Pickering NGS for the extended operation period. The Gaps associated with these Global Issues are related to Safety Factor 2, Safety Factor 4, Safety Factor 5 and the COP.

Twenty-four Global Issues are assessed as having a low impact on nuclear safety and are accordingly prioritized as Safety Significance Level 3. These Global Issues are mostly related to specific requirement elements of modern codes and standards. The justification for considering these as low nuclear safety impact is provided in Section 4 of each Global Issue Table in Appendix B.

Fifteen Global Issues are assessed as having a very low impact on nuclear safety, and are accordingly prioritized as Safety Significance Level 4. The majority of these Global Issues are related to OPG governance or specific requirement elements of modern codes and standards, or are administrative in nature. The justification for considering these Global Issues as very low nuclear safety impact is also detailed in Section 4 of each Global Issue Table in Appendix B.

13. Development of Proposed Resolution Plans

Proposed Resolution Plans have been developed for all Global Issues following the methodology described in Section 5.4, and are presented in Section 5 of each Global Issue Table in Appendix B. Each Global Issue table includes the following elements relevant to the proposed Resolution Plan:

i). Background Information and Resolution Strategy presented in Section 3 of each Global Issue table, with an evaluation of the Global Issue describing the nature of the associated gaps and a summary of the status of any work already underway or completed to address the Global Issue.

ii). A proposed Global Issue Resolution Plan presented in Section 5 of each Global Issue table, and comprised of one or more of the following elements:

- Proposed Resolution Statements (RS): A proposed activity is defined to address the Gap(s).
- No Further Action (NFA): Work is completed or will be done outside of PSR2 to address the related Gap(s), or information has been found to obviate the Gap(s).
- Acceptable Deviation (AD): The deviation in the Gap(s) has been assessed to have a Very Low Safety Significance Level, or a Low Safety Significance Level and a practicable resolution is not readily evident.
- Cross Reference (XRF): An action that addresses the Gap(s) is covered by a proposed Resolution Statement under a different Global Issue.

A proposed Resolution Plan element may address more than one Gap, or portions of more than one Gap. A Gap may be addressed by more than one proposed Resolution Plan element.

In developing proposed Resolution Plans for the 51 Global Issues, each of the Gaps identified in Part II from the reviews of the Safety Factor Reports, Complementary Reviews and CNSC staff reviews, is addressed, as well as the Expert Panel Gap identified in Section 15. In total, 35 proposed Resolution Statements are identified.

As discussed in Section 5.4, development of the proposed Resolution Plans considers whether the proposed resolution activities could be different for operation to 2024 (the planning basis for the units), or beyond 2024. Table 17 summarizes the Global Issues identified as being potentially impacted if a decision is made to extend operation of Pickering NGS beyond 2024. These Global Issues are largely related to fitness for service, aging or Condition Assessments of SSCs. If a decision is made to operate beyond 2024, these Global Issues would be re-evaluated and their proposed Resolution Plans would be updated if/as appropriate.

Table 17: Global Issues Potentially Impacted by Pickering NGS Operation Beyond 2024

Global Issue #	Global Issue Title
GI-1	Fitness for Service for Fuel Channels
GI-2	Fitness for Service for Feeders
GI-3	Fitness for Service for Steam Generators
GI-4	Fitness for Service for Reactor Components and Structures
GI-5	Completeness of Class 1 Piping/Components Service Limits Assessment (Excluding Major Components)
GI-7	Pickering Buried Piping Fitness for the Extended Operating Period
GI-8	Completion / Updating of the Condition Assessments
GI-10	IFB Condition
GI-12	Extending the Environmental Qualification of Equipment
GI-17	FFS of Fiberglass Reinforced Plastic Material for the Extended Operating Period
GI-19	FFS of Containment for the Extended Operating Period
GI-21	FFS of the Deaerator and the Deaerator Storage Tank for the Extended Operating Period
GI-22	COP Actions Related to Aging Management from SFR4
GI-24	Safety Analysis to Support the Extended Operating Period
GI-29	FFS of the Fuelling Machines and FM Bridge Ball Screws for the Extended Operating Period
GI-31	Deterministic Safety Analysis
GI-32	Implementation of REGDOC-2.4.2 PSA Requirements
GI-33	N285.0-12, General Requirements for Pressure-Retaining Systems and Components in CANDU Nuclear Power Plants
GI-43	Safety-Related Structures (Non-Containment) for Nuclear Power Plants
GI-49	FFS of PHT Auxiliary Piping Systems, and PHT Valves
GI-51	Fuelling with Pressure Tube Sag

The proposed Global Issue Resolution Statements presented in Section 5 of each Global Issue Table in Appendix B are inputs to the Integrated Implementation Plan phase of PSR2.

14. Ranking of Proposed Resolution Statements

Proposed Global Issue Resolution Statements presented in Section 5 of the Global Issue Tables in Appendix B are ranked using the methodology and Value Tree technique described in Section 5.5 and Appendix C. Acceptable Deviations and No Further Action statements do not go through the ranking process; only proposed Resolution Statements are ranked.

The results of ranking the proposed Global Issue Resolution Statements are summarized in Table 18 and detailed in Appendix C.

The proposed Global Issue Resolution Statements are sorted in ranked order, with the highest ranking first, in Table 18. Consistent with the methodology described in Section C.7, proposed Resolution Statements with the same ranking values are further sorted in order of those judged to be most important to the overall objective. For example, there are 5 proposed Resolution Statements with a ranking value of 100. The proposed Resolution Statement associated with Fuel Channel life cycle management (GI-1-RS3) is judged to be the most important among this group, whereas others such as measurements of the Calandria Tube/Liquid Injection Shutdown System nozzle gaps on Units 5-8 (GI-4-RS2) are judged to be of relatively lesser importance.

Table 18: Overall Ranking Results

GI-RS #	Proposed Resolution Statement Title	Normalized Ranking Value
GI-1-RS3	Update the Fuel Channels LCMP for Pickering 1,4 for the extended operating period.	100
GI-2-RS1	Update the Feeders Life Cycle Management Plan for Pickering 1,4 for the extended operating period based on updated fitness for service assessment.	100
GI-3-RS1	Update the Steam Generators Life Cycle Management Plan for Pickering 1,4 for the extended operating period based on updated fitness for service assessment.	100
GI-4-RS1	Update the Reactor Components and Structures Life Cycle Management Plan for Pickering 1,4 for the extended operating period based on updated fitness for service assessment.	100
GI-4-RS2	Perform measurements of Calandria Tube/Liquid Injection Shutdown System nozzle gaps on	100

GI-RS #	Proposed Resolution Statement Title	Normalized Ranking Value
	Units 5-8 to refine the gap closure rates. Using this new measurement data, update analyses as required, to demonstrate Fitness for Service.	
GI-24-RS1	Update Heat Transport System aging safety analysis models and perform the required safety analysis of events most impacted by aging (Small Break Loss of Coolant Accident (SBLOCA), Loss of Flow (LOF) and Neutron Overpower (NOP)) to support extended operation.	72
GI-27-RS2	Investigate and implement additional practicable design, operational and/or analytical enhancements to further improve Pickering 1,4 Severe Core Damage Frequency and Large Release Frequency (e.g., alternative emergency cooling water makeup).	72
GI-1-RS1	Complete CSA N285.8 Compliance Plan activities, including responding to comments.	70
GI-1-RS2	Review and revise if/as required the CSA N285.4 compliant Periodic Inspection Plans for Fuel Channels for Pickering NGS to cover the extended operating period.	70
GI-1-RS4	Update the structure of the Fuel Channels LCMP.	70
GI-5-RS1	Confirm the adequacy of the service limits assessments for Nuclear Class 1 Piping (Excluding Major Components) after accounting for any impact of environmental factors	70
GI-40-RS1	Ensure the completion of EME Phase 2 activities.	59
GI-48-RS1	Provide, as necessary, design and/or operational changes and commissioning/testing to facilitate required interconnection of Pickering 1,4 and Pickering 5-8 Fire Protection System water supplies to meet the safety intent of CSA N293-12 Clause 7.3.2.2 (d).	59

GI-RS #	Proposed Resolution Statement Title	Normalized Ranking Value
GI-8-RS1	Complete and update CAs for the piping systems and commodity groups in PSR2 scope for station operation for the extended operating period.	46
GI-8-RS2	Develop and implement a process to track and report aging-management-related actions from the Condition Assessment recommendations.	46
GI-10-RS1	Complete the Pickering 5-8 IFB Leakage Mitigation Project to mitigate leaks from IFB-B to the interspace.	46
GI-12-RS1	Complete EQA re-assessments to support the extended operating period.	46
GI-19-RS1	Demonstrate the FFS of the foundation steel H-piles for the Pickering A Reactor Building, Vacuum Building and Pressure Relief Duct at the Pickering site for the extended operating period.	46
GI-43-RS1	Perform the scope of inspections for non-Containment safety-significant civil structures as per the established Preventive Maintenance program (PM 00121151).	46
GI-26-RS1	Complete the emergency response projection enhancements identified in Action Item 2016-OPG-7469: Implementation of Emergency Response Projection Computer Code Upgrades.	38
GI-9-RS1	Complete the required assessment to support the current fuel basket stacking arrangements in the Pickering IFBs.	33
GI-25-RS2	Complete the re-categorization of CANDU Safety Issue CSI-IH6 for Pickering to Category 2. (Pickering 1,4 high-energy piping)	33
GI-27-RS1	Complete actions from PSA improvement Plan.	33

GI-RS #	Proposed Resolution Statement Title	Normalized Ranking Value
GI-6-RS1	Reassess the impact of the changes in the cable Criticality Coding and update the scope of the cable surveillance plan.	31
GI-7-RS1	Update the Buried Piping Program asset management plan and risk ranking for the extended operating period.	31
GI-43-RS3	Prepare Condition Assessments as appropriate for safety-significant civil structures for the extended operating period. Recommendations from these Condition Assessments will be tracked and reported along with those related to GI-8. This applies to non-Containment Safety-Related Civil Structures.	31
GI-47-RS1	Complete installation of locks on the 058 Yard Fire Protection System.	27
GI-43-RS2	Develop program governance using a risk based approach for aging management of safety-significant civil structures for the extended operating period. This applies to non-Containment Safety-Related Civil Structures.	26
GI-50-RS2	Assess the impact of extended operation on concessions against CSA N285.4	26
GI-31-RS1	Complete the Pickering NGS Implementation Plan for REGDOC-2.4.1.	22
GI-31-RS2	Prepare Implementation Plan update for REGDOC-2.4.1 including consideration of the impact of the extended operating period.	22
GI-32-RS1	Complete the activities in the REGDOC-2.4.2 Implementation Strategy and update the Strategy in the context of the additional operating period.	22
GI-50-RS1	Revise the N285.4 PIPs and governance to align with elements of N285.4-14	21

GI-RS #	Proposed Resolution Statement Title	Normalized Ranking Value
GI-25-RS1	Complete the re-categorization of the Large Break LOCA (LBLOCA) CANDU Safety Issues to Category 2.	19
GI-7-RS2	Update governance to reflect a graded approach in the event that leakage in fuel oil piping occurs.	5

The top five ranked proposed Resolution Statements in Table 18 contribute to meeting the fundamental objective of enhanced confidence in the fitness for service of SSCs (refer to Section 5.5 for the Value Tree fundamental objectives). These proposed Resolution Statements are determined to have the highest normalized ranking value of 100, and are associated with Global Issues related to fitness for service of Major Components, GI-1, GI-2, GI-3, and GI-4. Fitness for service of Pickering NGS SSCs is a key issue for OPG, and is being managed under the comprehensive programs that OPG has in place, including N-PROG-MA-0026, *Equipment Reliability* [47], N-PROG-MP-0008, *Integrated Aging Management* [48], and N-PROG-MA-0025, *Major Components* [49]. These programs ensure the condition of SSCs important to safety is well understood, the level of fitness for service is assessed, and effective actions are taken to maintain good plant condition. Work is actively underway to complete Condition Assessments and confirm assurance of fitness for service for safety-related SSCs for the extended operating period, and much of this work is already complete for 2024.

The next two highest ranked proposed Resolution Statements in Table 18 contribute to meeting the fundamental objective of enhanced confidence in the safety analyses. These are determined to have a normalized ranking value of 72 and are associated with Global Issues GI-24, which is related to safety analysis to support the extended operating period, and GI-27, which is related to Pickering 1,4 PSA. OPG has processes in place to ensure that aging effects associated with extended operation are accounted for in safety analysis, and the proposed Resolution Statement associated with GI-24 reflects the planned safety analysis to support Pickering NGS extended operation. The Pickering NGS PSA shows that the OPG risk-based Safety Goals for Core Damage Frequency and Large Release Frequency are met. The proposed Resolution Statements associated with GI-27 will enhance margins to these goals with emphasis on Pickering 1,4, and will consider physical and/or operational enhancements, in addition to analytical enhancements.

The proposed Resolution Statements with normalized ranking values less than 72 contribute, to a lesser extent, to meeting the fundamental objectives. All of the proposed Resolution Statements shown in Table 18 are inputs to the Integrated Implementation Plan phase of PSR2, and the Integrated Implementation Plan considers the ranking order shown in Table 18.

15. Pickering PSR2 Expert Panel

15.1. Overview

OPG established a third party technical Expert Panel to support the PSR2 Global Assessment process. The Expert Panel is comprised of experienced individuals who are familiar with the design and operation of Pickering NGS (and other nuclear plants) and have demonstrated leadership in the Nuclear Industry, participating in external review committees and initiatives.

The Expert Panel was given a broad mandate in terms of its activities, with its primary objective to provide guidance and counsel to both the Global Assessment Team and to OPG Pickering staff developing PSR2. The framework for these activities was based on the PSR2 Basis Document [1] and was further informed by, and was consistent with, the appropriate regulatory requirements [2] and industry guidance [3], [7], [8], [9].

The Expert Panel provided third party review of elements of the Global Assessment Report as they were being developed and subsequently of the Global Assessment Report itself, with support from other experienced individuals on an as-needed basis. The comments from the Expert Panel were reviewed and dispositioned by the Global Assessment Team and any findings were communicated to OPG for consideration in the Global Assessment Report.

The Expert Panel members, and their qualifications and experience, are discussed in Section 15.3.

15.2. Mandate

The Expert Panel completed specific tasks (e.g., document review) within the scope of the Pickering NGS Global Assessment Project as agreed to between OPG and the Global Assessment Team. Once assigned a task, the Expert Panel also provided third party technical feedback and counsel as appropriate to the Global Assessment Team or OPG. The Expert Panel was expected to identify and undertake additional tasks it deemed to be within the scope of its mandate, such as to identify additional review issues for consideration by the Global Assessment Team.

The Expert Panel focused on the Global Assessment Report, including:

1. The development of the Global Issues and Resolution Plans
2. The Global Issue Prioritization process
3. The Global Issue Resolution Statement ranking process
4. The defence-in-depth review
5. The overall justification for continued operation

Typically, the findings from the Expert Panel reviews were documented and discussed with the Global Assessment Team to come to an agreement on the dispositions. The agreed dispositions are incorporated into the Global Assessment Report.

Contact and communication with the Global Assessment Team and OPG was maintained during the Global Assessment Report development through both teleconferences and face to face meetings.

15.3. Members, Qualification and Expertise

The qualifications of the Expert Panel are given below.

J. Craig Sellers, B.A.Sc. (Chemical Engineering), P.Eng – Panel Chair

> Craig Sellers has over 37 years of extensive experience in the field of nuclear generation including positions as Commissioning Engineer, Authorized Shift Supervisor, Engineering Manager, Maintenance Manager, Senior Manager (Plant Design), and Director, Supply Planning. Craig retired in 2009 from the role of Chief Nuclear Engineer, OPG.
>
> Post retirement, Craig has filled numerous executive level positions including Vice President and Chief Engineer RCM Technologies and has actively participated in a variety of external activities with CSA, IAEA, and WANO/INPO. He is currently a member of the Bruce Power Nuclear Safety Review Board.

Dr. Keith C. Garel, PhD (Nuclear Engineering)

> Dr. Keith Garel has over 35 years of experience in the nuclear power industry including 25 years of nuclear safety and licensing experience where he performed a variety of functions including Safety Analysis Engineer, Technical Superintendent of Safety and Licensing at Pickering NGS, and Senior Manager – Operational Licensing – Nuclear Regulatory Affairs.
>
> Dr. Garel also possesses in excess of 10 years of experience performing engineering management functions that include managing engineering departments of disciplines varying amongst stress analysis, components and equipment, and project management of destiny projects for OPG as Project Manager Feeder Integrity Projects and the OPG Fuel Channel Life Management Project.
>
> Dr. Garel currently consults in a variety of areas including project management and project oversight, as well as managing task teams focused on resolving safety and licensing issues.

Michael K. O’Neill, B.Sc., M.Sc. (Physics), P.Phys, P.Eng

> Mike O’Neill has over 35 years of experience in nuclear engineering and operational support, including positions as Nuclear Safety Analysis Manager, Reactor Physics Manager and Reactor Safety Manager. Mike retired in 2011 from the role of Manager, Nuclear Safety and Technology, OPG.

Post retirement, Mike was heavily involved in OPG's post-Fukushima follow-up activities and currently is providing technical support in a variety of areas. Mike is the Chair of the CSA N290B Technical Committee on Reactor Safety and Risk Management. The scope of the N290B Technical Committee includes Periodic Safety Review, Probabilistic Safety Assessment, and BDBA standards.

15.4. Activities

The list of activities completed by the Expert Panel is given in Table 19.

Table 19: Expert Panel Activities Completed

Date	Description	Accountable	Status
Aug 2016	Review defence-in-depth methodology	Expert Panel	Complete
Sep 2016	Review Interim #1 Global Issue Development Methodology and proposed Resolution Plans[24]	Expert Panel	Complete
Oct 2016	Conduct Pairwise Comparison & Review Ranking Methodology	Expert Panel and Global Assessment Team	Complete
Nov 2016	Review Interim #2 Global Issue Development Methodology and proposed Resolution Plans	Expert Panel	Complete
Dec 2016	Review Interim #3 Global Issue Development Methodology and proposed Resolution Plans	Expert Panel	Complete
Feb 2017	Review Interim #4 Global Issue Development Methodology and proposed Resolution Plans	Expert Panel	Complete
Mar 2017	Review Interim Defence-in-Depth Assessment Rev 0	Expert Panel	Complete
Mar 2017	Review Preliminary Global Assessment Report (early draft)	Expert Panel	Complete
Apr 2017	Review Interim #5 Global Issue Development Methodology and proposed Resolution Plans	Expert Panel	Complete
May 2017	Review of the Pickering NGS PSR2 Strengths report	Expert Panel	Complete

[24] Global Issue Resolution Plans were developed iteratively as the Safety Factor Reports, Complementary Reviews and feedback from CNSC staff became available.

Date	Description	Accountable	Status
May – September 2017	Review draft Global Assessment Report	Expert Panel	Complete

Review of Global Assessment Methodologies

The Expert Panel reviewed all aspects of the Global Assessment Methodology.

Review of Global Issues

The Expert Panel provided technical advice and counsel on the development of the Global Issues. This included:

- Characterization of Global Issues
- Prioritization of Global Issues
- Development of Resolution Plans (Resolution Statements and Acceptable Deviations)
- Ranking of Global Issue Resolution Statements

Review of the Defence-in-Depth Assessment

The Expert Panel reviewed the defence-in-depth documentation, including refinement of Strengths and consideration of the aggregate impacts of Acceptable Deviations.

15.5. Expert Panel Findings

The PSR2 Expert Panel performed a detailed review of this version of the Global Assessment Report and supporting documents. The findings are as follows:

- The Global Assessment Report has been prepared in accordance with the PSR2 Basis Document [1], and in a manner consistent with regulatory requirements [2] and industry guidance [3], [7], [8], [9].
- The methodologies used to develop the Global Assessment Report are reasonable and aligned with previous Global Assessment Reports and international practices.
- One Expert Panel Gap, EP-1, is identified related to the impact of Pressure Tube sag on the ability to fuel the Fuel Channels for the period of extended operation.
- The identification of Global Issues is consistent with the Gaps identified in the PSR2 Safety Factor Reports and Complementary Reviews. The Global Issues are also consistent with the Expert Panel's knowledge of Pickering NGS and experience with Pickering NGS design and operation.
- The disposition of the Global Issues is reasonable, and the determination of "Resolution Statement", "No Further Action", or "Acceptable Deviation" is consistent with the PSR2 Basis Document and regulatory/international practices. The dispositions are also

aligned with the Expert Panel's knowledge of Pickering NGS and experience with Pickering NGS design and operation.

- The Defence-in-Depth Assessment accurately assesses the current provisions for defence-in-depth. The Defence-in-Depth Assessment also identifies the contribution of the enhancements proposed in the Resolution Statements.

The overall assessment of the Expert Panel is that this version of the PSR2 Global Assessment Report provides a balanced and accurate evaluation of Pickering station design, operation and supporting activities. The Expert Panel concurs with the overall conclusion of the Global Assessment Report, which is that the current plant design, operation, processes and management system will ensure continued safe operation of Pickering Units 1,4 and 5-8 both in the short term, and for extended operation.

Part IV: Assessment of Overall Acceptability of Operation of the Plant

Section	
#	**Title**
16	Pickering NGS Strengths Identified in PSR2

Appendix E – Strengths Used in the Defence-in-Depth Assessment
Appendix F – Proposed Global Issue Resolution Statement Summaries
Appendix G – Grouping of PSR1 Acceptable Deviations
Appendix H – Aggregation of Acceptable Deviations by Defence-in-Depth Level

16. Pickering NGS Strengths Identified in PSR2

This section describes the identification of Strengths in Pickering NGS design, operations and performance. The Pickering NGS Strengths are used in the Defence-in-Depth Assessment in Section 18 to demonstrate the "extent to which the safety requirements of defence in depth are fulfilled", as required by CNSC REGDOC-2.3.3 [2], and to support mitigation of Global Issues.

The Defence-in-Depth Assessment (Section 18) also includes a discussion of Pickering NGS design features that support defence-in-depth and evaluates the proposed Pickering NGS enhancements in the Global Issue Resolution Statements (refer to Section 13) and Pickering NGS Strengths (presented in this section) for their contribution to each level of defence.

CNSC REGDOC-2.3.3 [2] defines strengths as current practices that are "equivalent to or better than those established in modern codes and standards, practices". Section 3.1 of the PSR2 Basis Document [1] states that from Safety Factor reviews:

> "The Compliances (and groups of Compliances) are taken into the Global Assessment for consideration as Strengths."

Section 3.2.3 of the PSR2 Basis Document [1] states that:

> "Compliances that are equivalent to or surpass PSR2 Assessment Basis requirements or practices will be forwarded into the Global Assessment process for consideration as Strengths."

Therefore, positive findings in PSR2 are identified as possible strengths if there is clear evidence that Pickering NGS and/or OPG programs are equivalent to or surpass conformance with the provisions of modern requirements and practices or review task objectives.

Pickering NGS Strengths are identified by the Global Assessment team through a review of the following sources:

- **Safety Factor Reports**

  Safety Factor reviews provide assessments for all aspects important to the safety of an operating nuclear power plant. There are 15 Safety Factors used in the PSR2 review; 14 are identified in IAEA SSG-25 [3], and one additional Safety Factor (Radiation Protection) is identified in CNSC REGDOC-2.3.3 [2].

  Section 4.4 of each Safety Factor Report ([11] to [14] and [16] to [26]) was reviewed for:

  - Explicit statements of strength or discussions in the review task assessments that indicate a strength (e.g., program(s) relevant to the review task that are fully developed and implemented may indicate a strength).
  - Explicit statements of strength or discussions in the program effectiveness assessments (summarized in Appendix B of each Safety Factor Report) that may indicate a strength (e.g., no safety significant issues identified against the programs could be an indication of a strength).

- **Codes and Standards Assessments**

  The PSR2 assessments of modern codes and standards include a history of compliance assessments, including a summary of results of PSR1 assessments and their applicability to PSR2, and where appropriate, an updated assessment specifically for PSR2 ([56] through [59]).

  The assessments of codes and standards were reviewed to identify those with positive findings (i.e., conformance with safety-significant requirements). Significant positive findings may be an indication of a strength. Codes and standards that address the same or similar topics were assessed for strengths as a group.

- **Complementary Reviews**

  The Pickering B COP [5] actions and the FAIs [6] were reviewed to support identification of strengths.

- **Independent Third Party Assessments**

  Additional insights from third-party assessments (e.g., CNSC's Regulatory Oversight Report for 2015 [60] and assessments/reviews by international organizations) of OPG/Pickering NGS programs were reviewed for indications of strength. While these assessment reports are not used as explicit references for identifying specific strengths, they are useful for indicating areas of station operation with candidate strengths and may confirm insights from other sources. Where the reports imply 'met or exceeded performance objectives' or rated a Safety and Control Area as Fully Satisfactory for Pickering NGS, evidence of a strength was sought within other OPG documentation (e.g., performance indicator trends).

- **CNSC Feedback on PSR2**

  CNSC staff feedback from their review of the PSR2 submissions ([34] through [43]) was assessed for explicit statements of strength or discussions that may indicate a strength.

Where an individual source provides an indication of a strength, the reviews of other sources are used to confirm or contradict the indication. This approach precludes over-reliance on any single source. An additional step involved seeking input from staff (PSR2 project internal as well as external subject matter experts in broad areas) for potential areas of strength. The methodology and the list of Strengths were reviewed by the Pickering NGS Global Assessment Expert Panel and other expert reviewers with extensive knowledge of the Pickering NGS PSR2 project and design/operation of the Pickering NGS, to confirm that the results presented are reasonable and representative. This process resulted in refinements of the Strengths. Overall, the process is robust and provides a list of Strengths that is supported by references and by specific Pickering NGS experience.

A total of 24 Strengths are identified for Pickering NGS, as listed in Table 20 and described in Appendix E. For each Strength identified, a rationale for its inclusion is provided in Appendix E, as well as the source(s) containing supporting information.

Table 20: Strengths Identified for Pickering NGS

Strength ID	Strength Title and Description
S-01	Management
S-02	Effective Equipment Reliability Program
S-03	Major Components Program
S-04	System and Component Health Reporting
S-05	Implementation of Fukushima Action Items
S-06	Deterministic Safety Analysis
S-07	Probabilistic Safety Assessment
S-08	Operationalization of Probabilistic Safety Assessment

S-24	Advanced Technology to Support Radiation Protection

17. Acceptable Deviations Identified in PSR1

The aggregate impacts of Acceptable Deviations from PSR1 and PSR2 are assessed as part of the Defence-in-Depth Assessment methodology (described in Section 5.7). The PSR1 Acceptable Deviations are described in this section. The process for identifying PSR2 Acceptable Deviations during the development of proposed Resolutions Plans is presented in Section 13.

The 274 Acceptable Deviations from PSR1 [61] were assessed during the preparation of the Safety Factor Reports, to determine whether any are impacted by Pickering NGS operation beyond 2020. Accordingly, 34 of the PSR1 Acceptable Deviations were assessed in Reference [61] to be Gaps for PSR2. As these are already addressed in the PSR2 assessment, they are not included in the PSR1 Acceptable Deviation aggregate assessment described in this section. The remaining 240 PSR1 Acceptable Deviations, plus two additional PSR1 Acceptable Deviations identified during the PSR2 Global Assessment, are identified in Appendix G.

To facilitate the aggregate assessment, the PSR1 Acceptable Deviations are grouped according to topic, as shown in Appendix G. PSR1 Acceptable Deviations that are assessed as not having an impact, such as legacy document issues or minor document revisions, are identified as PSR1-AD-DOC and are not assessed for aggregate effects in the Defence-in-Depth Assessment in Section 18, as there is deemed to be no aggregate impact for these Acceptable Deviations. Thirty-three PSR1 Acceptable Deviations are assessed as PSR1-AD-DOC. PSR1 Acceptable Deviations that have already been addressed or that are not applicable to Pickering NGS are identified as PSR1-AD-NFA (No Further Action) and are not assessed for aggregate effects in the Defence-in-Depth Assessment in Section 18. Fifty-eight PSR1 Acceptable Deviations are assessed as PSR1-AD-NFA.

The remaining 151 PSR1 Acceptable Deviations are sorted into 22 groups and are confirmed to be applicable to PSR2. These PSR1 Acceptable Deviations are considered for their aggregate effects in the Defence-in-Depth Assessment in Section 18. The aggregate assessment is presented in Appendix H.

18. Defence-in-Depth Assessment

This section documents the assessment of the extent to which the safety requirements of defence-in-depth are fulfilled at Pickering NGS.

CNSC REGDOC-2.3.3 [2] indicates that the Global Assessment methodology "shall address and include... the extent to which the safety requirements of defence in depth are fulfilled". This assessment considers IAEA INSAG-10, *Defence in Depth in Nuclear Safety* [7], which describes the objectives, strategy, implementation and future development in the area of defence-in-depth in nuclear and radiation safety. Five levels of defence-in-depth are described in IAEA INSAG-10 [7], and an approach to assessment of defence-in-depth is described in IAEA SRS-46, *Assessment of Defence in Depth for Nuclear Power Plants* [8].

The Defence-in-Depth Assessment adopts the high-level elements of the approach to assessment of defence-in-depth described in IAEA SRS-46 [8], adapted appropriately considering that the assessment is performed in the context of a PSR and not as a stand-alone assessment.

The scope addresses the baseline plant and governance as of the freeze date of January 15, 2016, as identified in the PSR2 Basis Document [1]. The Defence-in-Depth Assessment is primarily based on this baseline, which takes into account the physical improvements and programmatic enhancements that have been implemented since Pickering NGS Units 1,4 and 5-8 first became operational.

The scope also considers the following elements of PSR2:

- The Strengths that have been identified in the PSR2 process, and how they support the baseline plant meeting the requirements of defence-in-depth.
- The positive impact on defence-in-depth of the enhancements associated with the proposed Resolution Plans.
- Confirmation that Acceptable Deviations do not have a significant adverse effect on defence-in-depth, either individually or when aggregated.

Defence-in-depth consists of a hierarchical deployment of different levels of equipment and procedures in order to maintain the effectiveness of physical barriers placed between radioactive material and workers, the public or the environment, during normal operation and postulated events at the plant.

Typically, five levels of defence-in-depth are considered. The objectives of each level and the means of achieving the objectives are described in IAEA INSAG-10 [7], as shown in Table 21.

Table 21: Defence-in-Depth Levels

Defence-in-Depth Level	Objective	Essential Means
Level 1	Prevention of abnormal operation and failures	Conservative design and high quality in construction and operation
Level 2	Control of abnormal operation and detection of failures	Control, limiting and protection systems and other surveillance features
Level 3	Control of accidents within the design basis	Engineered safety features and accident procedures
Level 4	Control of severe plant conditions, including prevention of accident progression and mitigation of the consequences of severe accidents	Complementary measures and accident management
Level 5	Mitigation of radiological consequences of significant releases of radioactive materials	Off-site emergency response

The objective of defence-in-depth Level 1 is the prevention of abnormal operation and system failures. Failure at this first level is an initiating event. Defence-in-depth Level 2 controls abnormal operation and detects failures. Level 3 ensures that specific safety systems and other safety features will be activated to limit the possible consequences of design basis accidents (DBAs). Level 4 limits accident progression by means of accident management measures in order to prevent or mitigate severe accident conditions with external releases of radioactive material. The objective of Level 5 is the mitigation of the radiological consequences of significant external releases through the off-site emergency response.

18.1. Methodology

IAEA SRS-46 [8] "describes a method for assessing the defence in depth capabilities of an existing plant, including both its design features and the operational measures taken to ensure safety." It is noted that the methodology described in IAEA SRS-46 [8] is not expressly for the purpose of a PSR. That is, IAEA SRS-46 [8] describes a way to perform a stand-alone assessment of defence-in-depth. Neither CNSC REGDOC-2.3.3 [2] nor IAEA SSG-25 [3] reference IAEA SRS-46 [8], yet both require that defence-in-depth be addressed within a PSR. Nevertheless, PSR2 uses the critical elements of IAEA SRS-46 [8], the safety principles, in conjunction with other information generated in PSR2, to execute a Defence-in-Depth Assessment, as described below.

The PSR2 Defence-in-Depth Assessment encompasses a systematic evaluation of the same aspects of defence-in-depth in a nuclear power plant as IAEA SRS-46 [8] but uses a topical approach that is based on the 15 Safety Factors set out in CNSC REGDOC-2.3.3 [2] (which includes a specific Safety Factor for Radiation Protection, in addition to the 14 from IAEA SSG-25 [3]). Therefore, the findings of the Safety Factor reviews and the proposed Resolution Plans (proposed enhancements) for the Global Issues are used together with defence-in-depth elements from IAEA SRS-46 [8] (based on the key areas, including the design, operation, maintenance, etc.) to develop an integrated approach to assess the defence-in-depth provisions of Pickering NGS[25].

Overall, the adequacy of the provisions for defence-in-depth is confirmed by demonstrating that the Pickering NGS design and operation are aligned with the specific safety principles covered in IAEA SRS-46 [8], taking into account the Strengths and proposed Resolution Plans identified in Appendix B, including the impact of Acceptable Deviations.

Considering the above, the assessment of the safety principles for the Global Assessment phase of PSR2 includes the following steps (described in more detail in Appendix D):

- Identification of the safety principles from IAEA SRS-46 [8] that are applicable to the defence-in-depth review.
- Establishment of the defence-in-depth levels impacted for each applicable safety principle (taken from IAEA SRS-46 [8]).
- Mapping of each safety principle to the relevant Safety Factor(s).
- Assessment of the adequacy of the Pickering NGS design and operation with respect to each safety principle.

As shown in Appendix D, the number of safety principles related to each level of defence is as follows:

- **Safety Principles Related to Level 1:** 36 of 52 safety principles
- **Safety Principles Related to Level 2:** 32 of 52 safety principles
- **Safety Principles Related to Level 3:** 38 of 52 safety principles
- **Safety Principles Related to Level 4:** 34 of 52 safety principles
- **Safety Principles Related to Level 5:** 7 of 52 safety principles

An overall assessment is then provided for each level of defence-in-depth, based on integration of the following:

- The conclusions from the assessment of the related safety principles (Appendix D).
- Consideration of Strengths identified in PSR2 and their impact on defence-in-depth (Appendix E).

[25] IAEA SRS-46 [8] provides this flexibility, as it states that the “assessment method described in this publication is not meant to replace the other evaluations required by national or international standards. Rather, it is intended to complement regulatory evaluations and to provide an additional tool for a better appreciation of the defence in depth capabilities of a plant.”

- The impact of proposed enhancements to defence-in-depth resulting from the proposed Resolution Statements (Appendix F).
- Assessment of the aggregate impact of the Acceptable Deviations on the defence-in-depth capability of the plant (Appendix G and Appendix H).

Finally, an overall summary is provided to confirm that Pickering NGS fulfills the safety requirements of defence-in-depth.

The main steps in the methodology and the sections of this report in which the results are documented are shown in Figure 2. Section 18.2 describes the current OPG management system and how it supports defence-in-depth, the current plant design features (including significant safety improvements that have been made since the start of operation of Pickering NGS Units 1,4 and 5-8) and the processes that support sustaining and enhancing defence-in-depth. This description establishes the baseline plant, processes and management system for the Pickering NGS Defence-in-Depth Assessment. Section 18.3 contains the assessment of each level of defence-in-depth, based on the baseline plant and taking into account the results of PSR2. The assessment is supported by information contained in various appendices, as shown in Figure 2. Finally, Section 18.4 provides the conclusions of this Defence-in-Depth Assessment.

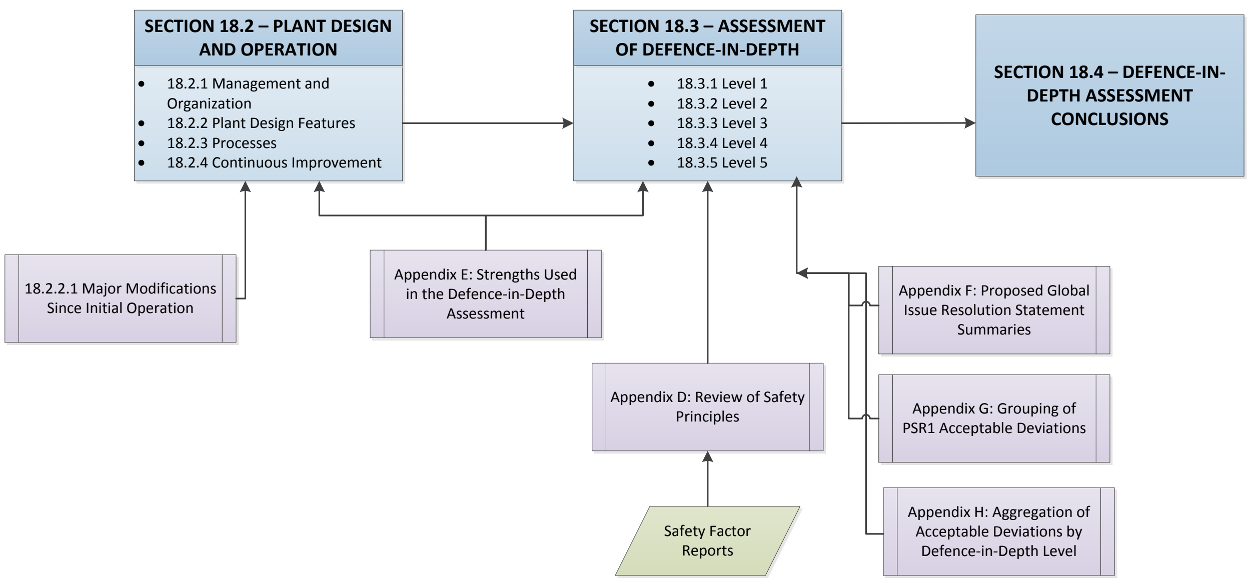

Figure 2: Methodology for Defence-in-Depth Assessment

18.2. Plant Design and Operation

This section describes the Pickering NGS management system and organization, the inherent and engineered design features, and the processes in place that maintain effective barriers between radioactive material and workers, the public and the environment, during normal operation and accidents.

18.2.1. Management and Organization

Nuclear safety is a core value at OPG. This is reflected in OPG Policy N-POL-0001, *Nuclear Safety Policy* [62] that is endorsed by OPG's Board of Directors. The policy places nuclear safety as the overriding priority above that of cost, schedule or production. It requires that all employees conduct themselves in a manner consistent with the behaviour of a healthy nuclear safety culture. Such conduct requires that staff always consider how their everyday activities can impact on the fundamental safety functions of the station.

OPG Charter N-CHAR-AS-0002, *Nuclear Management System* [50], which takes its authority from the *Nuclear Safety Policy* [62], gives authority to OPG Nuclear safety processes and defines responsibilities for the Nuclear Quality Program. OPG Standard N-STD-AS-0020, *Nuclear Management Systems Organizations* [63], outlines the implementation of the quality program and establishes the lines of authority and definition of duties. The well-defined organizational structure and strong lines of authority ensure that the *Nuclear Safety Policy* [62] is implemented effectively.

The safe operation and maintenance of Pickering NGS is under the direct accountability of the Director, Operations and Maintenance, who also ensures that the centre-led organizations effectively use resources to achieve performance targets. The quality and quantity of services provided by these centre-led support organizations are monitored by the Pickering Senior Site Vice President, who holds responsibility for establishing site requirements and priorities.

OPG identifies qualified and competent individuals for key positions with career development and succession planning being key elements in the management capability strategy. The corporate succession plan ensures that individuals with high leadership potential are identified to help continue excellence in nuclear safety.

Management responsibilities related to nuclear safety and protection of the environment are executed through a series of formal programs, as described in N-CHAR-AS-0002, *Nuclear Management System* [50]. The programs cover all aspects of operation including design modifications, engineering change control, maintenance and equipment reliability, integrated aging management, safety analysis, radiation protection, environmental management, security, conventional health and safety, fire protection, and public engagement. Key programs related to defence-in-depth are discussed in more detail in Section 18.2.3. PSR2 identifies that OPG's management system is a Strength (see Appendix E), as are Safety Culture and Use of Operating Experience and Research Findings. Strengths in these areas support defence-in-depth Levels 1, 2, 3, 4 and, for management, all five levels.

Managers at OPG ensure that tasks are executed as defined through programs, such as those listed above, that are specifically designed to achieve higher levels of nuclear and industrial safety, and higher unit reliability through event-free operation. This performance is accomplished through event-free tools such as pre-job briefings, post-job debriefings, self-checking programs, communications, self-assessments, and an observation and coaching program.

In summary, the existing corporate structure supports well-defined lines of responsibility throughout the organization. In particular, the appropriate functions are in place and adequately staffed to support and enhance nuclear safety at all levels of defence-in-depth.

18.2.2. Plant Design Features

Pickering NGS was designed and built to high standards using the principles of defence-in-depth. The design includes a number of robust active and passive safety characteristics, as well as engineered and administrative safety features. These characteristics and features prevent and mitigate accident progression.

18.2.2.1. Major Modifications Since Initial Operation

Numerous modifications have been made to Units 1,4 and Units 5-8 since the units commenced operation. These improvements reflect OPG's continuous improvement philosophy and they bring the station into closer alignment with modern codes and standards. The key modifications that have been made to Units 1,4 are as follows:

- **Fuel Channel Replacement:** As part of the Large Scale Fuel Channel Replacement Program, completed in 1987, all pressure tubes, end-fittings, shield plugs and garter springs were replaced in Units 1-4. This replacement has significantly extended the operating life of the units.
- **Shutdown System Enhancement:** To provide additional Shutdown System trip parameter coverage, additional trip parameters were added to the Unit 1,4 Shutdown System. These additional independent trip parameters, which use diverse instrumentation, are designated as SDSE and are independent from the original Shutdown System trip parameters and trip logic. Also, two additional shutoff rods were installed as part of SDSE bringing the complement of shutoff rods to 23 per reactor.
- **Control Computers:** The digital control computers used for the Reactor Regulating System and the Annunciation System were replaced on Unit 1 and Unit 4.
- **Fire Protection:** The Pickering NGS Units 1,4 Fire Protection Systems were comprehensively upgraded by the OPG Fire Protection Upgrade Program. These upgrades conform to the requirements of CAN/CSA N293-07, National Standard of Canada CAN/CSA-N293-07, *Fire Protection for CANDU Nuclear Power Plants*.
- **ECI Recovery System:** A design change to the configuration of the dump tank outlet piping was made to improve the performance and reliability of the Emergency Coolant Injection (ECI) Recovery System.

- **ECI Strainers:** Installation of additional large surface area strainers to reduce the probability of strainer blockage during recovery operation was completed.
- **Emergency Boiler Water Supply System:** The Emergency Boiler Water Supply (EBWS) System is designed to provide emergency water to the boilers of Pickering Units 1,4 following a postulated main steamline failure within the Pickering NGS A powerhouse. The emergency water is supplied from the discharge headers of the Pickering NGS Units 6 and 7 High Pressure Service Water System.
- **Containment Stack Monitors:** The design of the existing box-up activity monitoring arrangement at Pickering 1,4 was revised to improve Containment system reliability by separation of process and safety systems. This was achieved through the installation of additional radioactivity sensors, mounted external to Containment ventilation system pipework, to monitor instantaneous activity in the Reactor Building ventilation exhaust duct. The new design, which is based on a similar concept to that in place at Pickering 5-8 and Darlington, provides the capability to initiate box-up when required to limit off-site releases.
- **Service Water Systems:** Several design changes to significantly improve the capacity and reliability of the emergency Low and High Pressure Service Water Systems were implemented for Units 1 and 4. The design changes involve larger capacity emergency low and high pressure service water pumps and additional Class IV power service water load shedding components.
- **Inter Station Transfer Bus:** The Class III Inter-Station Transfer Bus (ISTB) is a standby power source to transfer power from Pickering Units 5-8 to the Pickering Units 1- 4 600 V Class II bus, which is normally fed via inverters. In the event inverters fail, the loads are transferred to the ISTB supplied by Pickering NGS Units 5-8.
- **Class II Inverters:** Replacement of the existing motor-generator sets used for providing continuous Class II power with electronic inverters was implemented on Units 1 and 4. This modification was implemented to improve the reliability of the Class II Power System.
- **Instrument Air System:** A design change to combine the low and high pressure instrument air compressors and relocate them to a higher elevation was implemented. Relocation of the compressors makes the instrument Air System less vulnerable to flooding. The new compressors supply instrument air to both Units 1 and 4.
- **Environmental Qualification:** As part of the Pickering A Return to Service Project, significant upgrades were made on operating units to satisfy Environmental Qualification requirements. Systems that are qualified include SDSA, SDSE, ECI (injection and recovery) and Moderator. Extensive PVC cable replacement was completed and all Hydrogen Igniters were replaced.

  A number of other Environmental Qualification initiatives have also been completed. The most significant is the major Environmental Qualification retrofit undertaken in the mid-1980s to improve mitigation of powerhouse harsh environment events. Modifications included strengthening the “H” line wall and the Control Equipment Rooms, protection of Class I and Class II electrical distribution systems, provision of a qualified heat sink and a Powerhouse Venting System with automatic initiation on temperature or pressure.

- **Seismic Assessment:** A seismic assessment was performed to evaluate the seismic capacity of SSCs required to perform the Control, Cool, Contain and Monitoring functions and to identify necessary seismic upgrades. Low seismic capacity components were replaced, structure and component anchorage was upgraded and potential seismic interactions were dispositioned for the return to service of Units 1 and 4. The list of seismic upgrades included:
  - Boiler Room shield wall upgraded
  - Switchgear and panel anchorage upgraded
  - Anchoring of heat exchangers in Vacuum Building basement enhanced
  - Standby Generator oil pump house masonry block wall reinforced
  - Supports for Standby Generator batteries enhanced
  - Supports for Class I batteries enhanced
  - Main Control Room (MCR) and Control Equipment Room panel anchorage upgraded
  - Control Equipment Room structural upgrades
  - Rerouting emergency air supply for airlocks
  - Anchoring Temporary Breathing Air System near emergency Low Pressure Service Water pumps
  - Enhancing supports for bleed valves
  - Enhancing spring hangers
  - Restraining gas bottles and fire extinguishers
  - Improving supports for Reactor Building Air Cooling Units
  - Reviewing proximity issues for various valves
  - Improving Deaerator Storage Tank Anchoring System
  - Providing lateral restraints for the high pressure feedwater heaters
  - Reviewing the Fuel Channel positioning assembly rod
  - Reviewing anchor bolts used on the fuelling machine support column
  - Upgrading mercoid switches
  - Upgrading relays

- A seismic Abnormal Incident Manual was issued and staff has been trained to respond to a seismic event
- Periodic testing of systems credited in seismic analysis
- Pressure Relief Duct analysis
- Piping supports on Recirculating Cooling Water piping

Also, administrative controls have been implemented to ensure that seismic qualification of Pickering NGS Units 1,4 seismic success path SSCs is maintained for the life of the facility.

The key modifications that have been made to Units 5-8 are as follows:

- **Third Emergency Power Generator:** An additional source of power to the Emergency Power System, consisting of three diesel generators capable of delivering a total of 2.5 MW, has been added to Units 5-8 to provide additional redundancy in the Emergency Power System.
- **SG Governor and Controls Upgrade:** This modification was a proactive strategic improvement initiative to maintain Class III power reliability/availability by replacing fuel governor, metering, delivery and control logic systems for the Standby Class Ill Power Generators.
- **Fire Protection Upgrades:** New Fire Detection Systems were installed in the Main Control Room, Control Equipment Rooms, and Cable Spreading Area. Turbine Generator and Transformer fire suppression systems were replaced with modern technology.

In addition, a number of other major improvements have been made that apply to Units 1,4 and Units 5-8. These are:

- **Electrical Power System:** The Electrical Power System at Pickering NGS has been enhanced through design modifications, such that the units are equipped with multiple sources of backup electrical power to ensure that controls and equipment important to safe operation are available during normal and abnormal conditions. These are:
    - Site Electrical System – This distribution system can be used for transferring back-up auxiliary power to any of the unit Class IV systems (High Pressure ECI pump motors, ECI-associated motorized valves for each of Units 1,4 and the electrical services of any single unit that has lost its Class IV power).
    - The Auxiliary Power System is a back-up power supply system that supplies power to selected Group 1 Class IV loads following a sustained loss of Class IV power across Pickering NGS. The system performs this function by supplying power to the Site Electrical System.

  These improvements are assessed as a Strength for the Electrical Power System (see Appendix E).

- **Hydrogen Igniters and Passive Auto-catalytic Recombiners:** A Hydrogen Ignition System has been provided in Units 1,4 and Units 5-8 to safely combine any hydrogen (or deuterium) gases that may be generated during certain scenarios. In addition, Passive Auto-catalytic Recombiners have been installed to control Containment hydrogen levels at reduced hydrogen generation rates, thereby eliminating reliance on the Hydrogen Ignition System in the longer term.
- **Critical Safety Parameter Monitoring:** The capability to monitor post-accident conditions remotely from the Main Control Room is provided in the SDSE Instrument Rooms for Units 1,4 and in the Unit Emergency Control Centre for Units 5-8.
- **Emergency Mitigating Equipment**: Emergency Mitigating Equipment has been provided for an additional makeup water supply for accidents beyond the design basis. Portable diesel-powered pumps can be deployed and can provide cooling water make-up to the secondary side of the boilers, to the Heat Transport System and to the Moderator. Portable diesel-powered generators can provide power for critical monitoring following an extended loss of all AC power event. Additional major Fukushima Project design modifications that have been installed include enhancements to water makeup/cooling capability for the IFBs. In addition, implementation of Phase 2 Emergency Mitigating Equipment modifications is in progress. Phase 2 Emergency Mitigating Equipment provides restoration of power to station equipment for sustained core cooling and restoration of Containment coolers to improve control of Containment pressure following BDBAs.

In summary, Pickering NGS has been continually upgraded and extensively modernized over its decades of operation to align it, as much as practicable, with current industry best practices. Many of the improvements listed in this section are further described in Section 18.3 in terms of how they support defence-in-depth.

18.2.2.2. Current Plant Design Features Important to Defence-in-Depth

Taking into account the major modifications described in the previous sub-section, the key design features of Pickering NGS that are important to the assessment of defence-in-depth are as follows:

- **Quality in Design:** The design and construction of Pickering NGS was undertaken under a formal quality assurance regime. Rigorous quality assurance processes were put in place and have been updated as improved standards become available for design analysis, stress analysis, material control and traceability, fabrication, in-process inspection, installation and welding, commissioning, non-destructive examination, and inspection.

  Currently, design modifications are performed under OPG Program N-PROG-MP-0001, *Engineering Change Control* [64], which meets modern rigorous quality assurance requirements. The engineering change control program defines a systematic process and methodology for controlling design modifications for plant SSCs.

- **Redundancy, Separation and Diversity:** In addition to high quality standards, critical safety functions are diverse and physically separated from process control functions. Redundant components are used where possible, so that the failure of a single component does not cause system failure. The Pickering NGS Units 1,4 and 5-8 designs include protection against common cause events; the design includes provisions to prevent the loss of safety functions due to damage to multiple SSCs.

  For Units 5-8, redundant equipment and circuits are separated and grouped (Group 1 and Group 2) to ensure the safety of the station following a common mode event. Each group is capable – independently of the other group – of safely shutting down the reactor, cooling the Fuel and providing the operator with indications of system conditions.

  Units 1,4 systems have been either qualified or retrofitted to function as required for a given common mode event by ensuring effective separation and diversity. Hazard assessments have been performed that confirm the capability of the design to perform the required safety functions following postulated common mode events.

- **Multiple Barriers:** Five physical barriers exist between the radionuclides and the public. They are the ceramic uranium dioxide fuel matrix, the metallic Zircaloy fuel cladding, the piping that comprises the Primary Heat Transport System boundary, the Containment boundary, and the exclusion zone around the station.

  The first four barriers prevent radioactive release to the environment. So long as they are intact, very little radioactive material will escape from the Containment. The exclusion zone utilizes the concept of distance from the source to mitigate radiological consequences if all of the first four barriers are breached.

- **Radiation Protection in Design:** During the initial design stage, emphasis was placed on the reduction of occupational radiation doses and limiting releases of radioactivity to the environment. The design of Pickering NGS ensures that the layout and operation of facility SSCs and processes are consistent with established radiation protection guidelines and contribute to maintaining occupational radiation exposures ALARA.

  Pickering NGS uses dynamic learning activities to provide workers an opportunity to practice radiation protection fundamentals in a simulated radioactive work environment using remotely controlled radiofrequency technology. OPG has implemented remote reading of radiation detection instrumentation and real-time data transmission to facilitate improved job planning and awareness of current radiological conditions.

  Specific design features at Pickering NGS to control radiation dose include the use of shielding, ventilation and emissions control, radiological zoning and the provision of area radiation monitoring equipment. The use of shielding and ventilation control reduces exposure to external radiation and airborne radioactive material, respectively. The use of emissions control reduces the doses to members of the public.

  The use of advanced technology to support radiation protection is a PSR2 Strength. This Strength demonstrates OPG's commitment to continuous improvement in radiation protection.

- **Reactor Control:** The plant systems are controlled to remain within their operating ranges. The control systems in Pickering NGS have been designed to maintain the reactor operating conditions within the normal operating range, and to effectively respond to transients to avoid the need for safety system actuation.

  Reactor control is highly reliable and prevents process upsets due to measurement failures, etc., with a high degree of redundancy in control devices and process measurements.

- **Automatic Shutdown Systems:** Pickering NGS has highly reliable Shutdown Systems for safety purposes that are independent of the equipment and processes used to control the reactor power and that are poised at all times during at-power operation.

  The Pickering NGS Units 5-8 have two independent, fast-acting and very effective Shutdown Systems. The independent Shutdown Systems are Shutdown System No. 1 (SDS1) (shutoff rods) and Shutdown System No. 2 (SDS2) (Gadolinium injection into the Moderator). Both Shutdown Systems are capable of shutting the reactor down fast enough for all DBAs, such that all limits are met. Both Shutdown Systems can also be manually activated. Both Shutdown Systems are fail safe and will shut down the reactors if electrical power to the system is lost.

  When Pickering NGS Units 1,4 began operation in the early 1970s, their design included a single Shutdown System with two diverse means of inserting negative reactivity into the core: (1) Dropping shutoff rods; and (2) Dumping the Moderator from the Calandria. The original Units 1,4 Shutdown System has been enhanced by retrofitting a Shutdown System Enhancement (SDSE) that provides sets of triplicated sensors and trip logic that are independent of those of the original Shutdown System (SDSA) to increase the reliability of actuation of the shutdown function, achieving system reliability targets for all events. Both systems can achieve their safety function without power or operator intervention, and they can also be manually activated.

- **Heat Removal:** Pickering NGS reactors are equipped with a Heat Transport System that effectively removes heat from the Fuel under normal operating conditions. The system is also effective in responding to anticipated transients and accidents within the design basis, supplemented by the emergency makeup water systems included in the design.

  In normal operation, heat is removed from the Fuel to the Steam Generators by the forced flow of coolant in the Heat Transport System. Steam generated in the Steam Generators is cooled in the condenser by the Condenser Cooling Water System, which rejects the heat to the ultimate heat sink (lake).

  For low power operation and when the reactor is shutdown, the Shutdown Cooling System cools down the Heat Transport System and maintains cooling for an indefinite period of time. The Shutdown Cooling System provides cooling for the Heat Transport System during outage operation and is designed to provide core cooling with the Heat Transport System depressurized to permit maintenance.

In the unlikely event of a pipe break in the Heat Transport System, the ECI System is designed to refill the Heat Transport System, and to provide coolant makeup and heat sink capability in the long term.

For postulated events involving a loss of Steam Generator inventory, a backup boiler water system (the Boiler Emergency Cooling System) is available to remove the decay heat generated in the Fuel. In the short term, the Boiler Emergency Cooling System provides water to Units 1,4 and Units 5-8 for reactor decay heat removal by the boilers for accident situations initiated by or leading to failure of the normal feedwater supply.

For long-term cooling for postulated events involving a loss of Steam Generator inventory, the Emergency Boiler Water Supply System provides emergency water to the boilers of Pickering NGS Units 1,4. In addition, the Emergency Water System is a system supplying long-term emergency makeup to the Units 5-8 boilers, Heat Transport System, ECI recovery heat exchangers, Containment air coolers and the Moderator. The Emergency Water System is powered from the Emergency Power System.

One of the operationally proven safety features at Pickering NGS is the ability to cool the Fuel through natural circulation in the event of a loss of forced flow in the Heat Transport System.

Emergency Mitigating Equipment provided as part of the implementation of lessons learned from the 2011 Fukushima accident can be deployed to prevent significant Fuel damage in the longer term (several hours) following a station blackout. Specifically, Emergency Mitigating Equipment has been provided for an additional makeup water supply for accidents beyond the design basis. Diesel-powered pumps are deployed to draw in lake water to provide cooling water make-up to the secondary side of the boilers, to the Heat Transport System and to the Moderator.

PSR2 identifies a Strength for Heat Removal due to the comprehensive and overlapping suite of heat removal provisions.

- **Containment:** Pickering NGS Containment is a robust Containment System structure that is provided to mitigate the effects of an unlikely Heat Transport System piping break, or other postulated initiating events, by limiting the release of radionuclides to the environment.

  The principle of Negative Pressure Containment is employed in the Pickering NGS. A Vacuum Building, maintained at a very low subatmospheric pressure, is linked to the Reactor Buildings by a pressure relief system. This arrangement ensures that the pressure within the Containment Boundary will be brought below the surrounding atmospheric pressure within a short time following a pressure rise within a Reactor Building. Long-term control of Containment pressure is accomplished through controlled venting via the Filtered Air Discharge System. The purpose of this system is to maintain Containment sufficiently sub-atmospheric following an accident and to provide a filtered and monitored pathway to the environment.

A Hydrogen Ignition System is provided to safely combine any hydrogen (or deuterium) gases generated in Containment following postulated events. The system is capable of addressing very low concentrations of hydrogen in air/steam mixtures, thus preventing the occurrence of high concentrations of hydrogen in Containment. In addition, Passive Auto-catalytic Recombiners have been installed to control Containment hydrogen levels at reduced hydrogen generation rates, and therefore eliminate reliance on the Hydrogen Ignition System in the longer term. The purpose of these two systems is to prevent a potential challenge to Containment integrity by keeping the overall concentration of hydrogen very low.

- **Monitoring Capability:** Values of important plant parameters are displayed in the Main Control Room to ensure that operators have clear and unambiguous indications of the status of plant conditions important for safety, especially for the purpose of identifying and diagnosing the automatic actuation and operation of a safety system or a challenge to defence-in-depth.

  Each Main Control Room contains the main control panels for all the generating units (Units 1,4 or Units 5-8). Each unit has its own control panels, and the panels for all units are of the same form. Two additional panels are provided for common equipment and electrical controls. All indications and controls essential for operation are located on the Main Control Room panels. When the Main Control Room is not available for any reason, the reactor can be monitored and can be safely shut down and maintained in that state indefinitely from the SDSE Instrument Rooms (Pickering Units 1,4) or the Unit Emergency Control Centre (Pickering Units 5-8).

  Also, post-accident monitoring capability of the critical safety parameters is available. By monitoring critical safety parameters and following critical safety parameters restoration procedures via field actions, it is possible to maintain the Control, Cool, Contain and Monitor safety functions externally from the Main Control Room. Capability to monitor post-accident conditions remotely from the Main Control Room is provided in the SDSE Instrument Rooms for Units 1,4 and in the Unit Emergency Control Centre for Units 5-8.

- **Standby Power Systems:** The reactors are equipped with multiple sources of electrical power to ensure that controls and equipment important to safe operation are available. The majority of the on-site power systems are supplied by the unit generator, Standby Generators and batteries, and are designated as Group 1. The Group 1 electrical power systems are divided into the following four classifications:

  - **Class I:** Direct Current (DC) supplies (backed up by batteries) for auxiliaries, control, protection, and safety related equipment.
  - **Class II:** Alternating Current (AC) supplies (backed up by batteries) for control power and supplies for safety-related auxiliaries, instrumentation, protection, and control equipment.
  - **Class III:** AC normally supplied from Class IV power, backed up by the Standby Generators, to safety-related equipment and auxiliaries.
  - **Class IV:** AC supplied from the bulk electrical grid and Unit generators, backed up by the Site Electrical System and the Auxiliary Power System.

The Auxiliary Power System is a back-up power supply system that supplies power to selected Group 1 Class IV loads following a sustained total loss of Class IV power across Pickering NGS.

- **Site Electrical System** – The Site Electrical System is a standby power supply for the Class IV distribution system at both Units 1,4 and Units 5-8. The power source for the Site Electrical System is either the Bulk Electrical System or one or more of the generating units at Pickering NGS or the Auxiliary Power System. The primary purpose of the Site Electrical System is to provide power to the High Pressure ECI pumps.

- **Emergency Power**: The purpose of the emergency power system is to provide power to support critical safety functions during Common Mode events that lead to the loss of Group 1 power. The following comprises emergency power at Pickering NGS:
  - The seismically-qualified Emergency Power System for Units 5-8 supplies power to a specific portion of the Safety-Related Systems in the station. There are 3 separate generator sources supplying power to the Emergency Power System.
  - The Inter Station Transfer Bus supplies power from Pickering Units 5-8 to essential Class II loads at Pickering Units 1,4.
  - The Standby Generators, both the Class II inverters, and the Class I rectifiers at Pickering Units 1,4 are seismically assessed and credited.

  As noted previously, the Pickering NGS electrical system is considered a Strength (see Appendix E) due to the multiple and overlapping provisions and redundant supplies.

- **Protection Against Common Mode Events:** The Pickering NGS Units 1,4 and 5-8 design includes protection against common cause events. The design includes provisions to prevent the loss of safety functions due to damage to multiple SSCs resulting from a common cause. For Units 5-8, redundant equipment and circuits are separated and grouped (Group 1 and Group 2) to ensure the safety of the station following a common mode event. Each group is capable, independently of the other group, of safely shutting down the reactor, cooling the Fuel, and providing the operator with indications of system conditions. For Units 5-8, seismically qualified Emergency Power and Water Systems are provided to support nuclear safety loads following significant seismic events. Units 1,4 systems have been either qualified or retrofitted to function as required for a given common mode event by ensuring effective separation, diversity, and robustness.

  The Pickering NGS design addresses dependent failures, using separation of redundant SSCs for responding to common mode events. Hazard assessments have been performed that confirm the capability of the design to perform the required safety functions following postulated common mode events.

- **Inspectability of Safety Equipment:** Periodic inspection is the non-destructive examination of nuclear equipment, the failure of which can have adverse effects. To support this activity, the safety systems and their support systems are designed to facilitate testing and inspection to ensure that the plant meets or exceeds safety standards.

- **Maintain Subcriticality:** A criticality hazard is not possible with fresh Fuel or with irradiated natural uranium Fuel bundles stored in the IFBs. This is because natural uranium Fuel bundles and light water cannot be made critical. Hence, no criticality concern exists in handling new Fuel or Fuel in the IFBs.
- **Beyond Design Basis Accident Management:** Pickering NGS has implemented and is in the process of further enhancing significant preventive and mitigating modifications to strengthen defence-in-depth against BDBAs, including severe accidents. Emergency Mitigating Equipment Guidelines and Severe Accident Management Guidelines are in place to mitigate accident progression and protect Containment integrity.

  A key line of defence for BDBAs is Emergency Boiler Makeup using Emergency Mitigating Equipment. An additional line of defence is Emergency Mitigating Equipment to provide makeup water to the Moderator. These features are capable of limiting core damage for most BDBAs.

  Additional major Fukushima Project design modifications include:

  - Passive Auto-catalytic Recombiners on all units to supplement the existing Hydrogen Igniters for control of hydrogen in Containment.
  - Enhancements to water makeup/cooling capability for the IFBs.

  In addition, implementation of Phase 2 Emergency Mitigating Equipment modifications is in progress. Phase 2 Emergency Mitigating Equipment includes restoration of power to key station equipment for core cooling and monitoring and to Containment coolers to enhance control of Containment pressure following BDBAs.

  Instrumentation and diagnostic aids to support deployment of Emergency Mitigating Equipment are available to the operators.

  PSR2 identifies a Strength for implementation of Fukushima Action Items (see Appendix E) on the basis that OPG has been proactive and a leading organization in identifying and implementing lessons learned from the 2011 Fukushima accident.

18.2.3. Processes

Pickering NGS is operated and maintained in accordance with current nuclear industry codes and standards consistent with regulatory and safety requirements and industry best practice. Normal plant operation is controlled by detailed, validated and formally approved procedures. In addition, emergency operating procedures are established and implemented to ensure effective operator response to abnormal events. Many of Pickering's operating, maintenance, engineering and other support programs and processes are assessed as Strengths.

OPG has established extensive programs and procedures and employs qualified staff to safely and effectively manage the nuclear plants. The programs and training were developed based on regulatory requirements, CSA standards, IAEA Guides, WANO recommendations and best nuclear industry practices from around the world. As part of continuous improvement, the programs and training are kept up to date, based on self-assessments, benchmarking, and ongoing use of industry OPEX.

OPG has implemented a modern Nuclear Management System (discussed in Section 18.2.1), that governs plant activities ranging from human performance, engineering, operations, maintenance, to environmental management, and support nuclear safety at all levels of defence-in-depth. These programs are aligned with modern industry best practice as evidenced by the few PSR2 Gaps identified in the related Safety Factor Reports, and they typically support multiple levels of defence-in-depth. Some of the key programs are listed and summarized below:

- **Quality Assurance Program:** OPG Charter N-CHAR-AS-0002, *Nuclear Management System* [50] and supporting documents referenced in the charter establish the Nuclear Management System for OPG Nuclear, which assures that systems, equipment and activities are of the required quality throughout the life of the nuclear facilities.
- **Engineering Change Control:** OPG Program N-PROG-MP-0001, *Engineering Change Control* [64] ensures that all modifications to plant SSCs, including software and station engineered tooling, are planned, designed, installed, commissioned, decommissioned, placed into service or removed from service within the SOE, design basis and plant licensing conditions. It defines a systematic process and methodology for controlling design modifications for plant SSCs to meet the requirements of CSA N285.0, *General Requirements for Pressure-Retaining Systems and Components in CANDU Nuclear Power Plants* and CSA N286, *Management System Requirements for Nuclear Power Plants*.

  An aspect of this program, specifically the implementation of Human Factors Engineering, is identified as a Strength for Pickering NGS (see Appendix E).
- **Equipment Reliability:** OPG Program N-PROG-MA-0026, *Equipment Reliability* [47] defines the requirements for establishing and maintaining optimum levels of reliability for components important to nuclear safety, production, and environmental protection. Reliable performance of components means very low numbers of component failures, degraded equipment condition is minimized, and redundancy is maintained on key systems.

  The Equipment Reliability Program contains the following elements which ensure ongoing high levels of reliable performance of critical components:
  - Identifying critical components that require focused attention.
  - Specifying the required maintenance strategies to maintain high levels of reliability.
  - Executing predictive maintenance and preventive maintenance programs.
  - Monitoring system and component condition and implementing plans to restore and maintain system and component health.
  - Taking prompt and effective action, when critical equipment fails, to understand the technical and organizational causes and to prevent a recurrence.

- Identifying and predicting aging and obsolescence issues on important components and embedding mitigating strategies and actions into the business plan.

Pickering NGS's Equipment Reliability Program implementation and execution of the program is a station priority. This program is identified as a Strength for Pickering NGS. System Health reporting, which is an integral element of the Equipment Reliability Program, is also identified as a Strength.

- **Risk and Reliability Program:** OPG Program N-PROG-RA-0016, *Risk and Reliability Program* [54] establishes a framework for the development and use of PSA as a means to manage radiological risks from nuclear accidents and to contribute to safe operation of the reactors. Through execution of this program and its elements, risks from nuclear accidents are identified, monitored and controlled.

  An aspect of this program, specifically Operationalization of Probabilistic Safety Assessments, is identified as a Strength for Pickering. The PSA is used to support conduct of engineering, maintenance and operation at Pickering NGS.

- **Reactor Safety Program:** OPG Program N-PROG-MP-0014, *Reactor Safety Program* [65] defines organizational responsibilities and key program elements for the management of issues related to deterministic nuclear safety analysis, generic safety issues (CANDU Safety Issues) and the following components of safe operation:
  - Safety Analysis Basis
  - SOE
  - BDBA Management
  - Safety Reports

  Deterministic Safety Analysis for Pickering NGS is assessed as a Strength for Pickering NGS. In addition, implementation of the SOE program is identified as a separate Strength.

- **Human Performance Program:** OPG Program N-PROG-AS-0002, *Human Performance* [66] is executed through a series of documents that support management of human performance. Collectively, these documents lay the groundwork for improving and sustaining performance. Specifically, this program provides guidance to reduce the probability and consequences of human error associated with the worker – machine interface required to operate, maintain and support Pickering NGS.

  The Event Free Day Reset indicator is one of the means OPG uses to identify human performance events. The indicator reflects the effectiveness of management in reducing errors and improving organizational processes and activities to reduce the significance and frequency of human performance events.

  The indicators have continually improved at Pickering NGS. Performance improvement has been accomplished by effectively identifying human performance events, investigating the causes to determine corrective actions, performing trending and analysis to identify reoccurring and common issue areas and communicating the results throughout all levels of the organization.

Conventional Health and Safety, a key indicator of the Human Performance Program, has met or exceeded performance objectives and all applicable regulatory requirements.

A separate assessment has been performed to identify Strengths in Pickering NGS. These are listed in Appendix E. Some of the Strengths have also been recognized by external organizations, which indicates that Pickering not only has strong organizational structure and procedures, but also that staff perform in accordance with high safety standards, demonstrating an organization with a strong nuclear safety culture. This is also identified as a Strength.

18.2.4. Continuous Improvement

The continuous improvement process through which OPG strives to improve the safety and performance of its nuclear power plants, is longstanding, ongoing, and covers all aspects of operation. Current performance is compared to management expectations, industry standards of excellence, internal and external OPEX, and regulatory requirements to identify areas with opportunities for improvement, prepare action plans and incorporate enhancements.

Established programs and processes are used to identify and address areas for improvement. OPG participates with industry partners in developing new or revised codes and standards, in research and development activities, in the application of emerging technologies, and in the exchange of OPEX. This is done through membership in organizations such as WANO, INPO, the CANDU Owners Group, the CSA and the Electric Power Research Institute.

In particular, there is ongoing improvement as a result of operating experience from the 2011 Fukushima accident.

Following the March 2011 earthquake in Japan, the safety systems at the Fukushima Daiichi Nuclear Power Plant operated as designed and the reactors were automatically shut down. However, the tsunami that followed disabled power to critical support systems.

OPG acted promptly to understand what had happened at Fukushima Daiichi and confirmed that the OPG nuclear fleet remained safe for continued operation. OPG has completed additional assessments including those requested by the CNSC to review the impact of a similar event (i.e., an event resulting in a total loss of all AC power, subsequently resulting in a total loss of heat sinks) at OPG stations. Enhancements to provisions to maintain or re-establish the Control, Cool, Contain and Monitoring safety functions were assessed to determine those that are most practical to implement and also meet specified requirements. Several enhancements have been implemented and additional ones are being implemented, as discussed under BDBA Management in Section 18.2.2.2.

From a PSA perspective, the Pickering NGS Units 1,4 and 5-8 Level 1 and Level 2 At-Power Internal Events Risk Assessments have been updated as part of the Fukushima Action Item update, and demonstrate the benefits of the Fukushima enhancements.

A *Mutual Aid Agreement for Nuclear Emergency Support* [67] is in place with all Canadian nuclear utilities to provide support in the event of an emergency.

OPG continues to have a strong presence in international forums and with all operators of Canadian nuclear generating stations to ensure that the lessons learned from the 2011 Fukushima accident are applied at Pickering NGS.

As noted previously, implementation of Fukushima Action Items is identified as a Strength for Pickering NGS.

18.3. Assessment of Defence-in-Depth

The concept of defence-in-depth has been applied at the Pickering NGS design stage and throughout its operation over a period of several decades. At the design stage, the focus was on the first three levels of defence-in-depth, i.e., prevention of operation outside normal operating conditions, control of abnormal conditions, and provision of safety systems to effectively mitigate DBAs. For example, defence-in-depth Level 1 systems, i.e., process systems, are designed so that any failure in the system is not propagated to the control systems that control these processes. Similarly a failure in a control system does not propagate to the next level of defence-in-depth, i.e., the safety systems. This is accomplished through design of reliable systems and adequate separation of the control systems from the safety systems. Internationally this is achieved by ensuring adequate buffering of any components shared between the control and safety systems so that the failure cannot be propagated. In CANDU reactors, including Pickering NGS, this is achieved through separation of the control and safety systems. Defence-in-depth Level 2 is achieved by monitoring changes from normal operating conditions by both the Reactor Regulating System and the Special Safety Systems. Digital computerized monitoring of parameters important to safety is used in the design of the Reactor Regulating System. Level 3 includes the provision of inherent safety features, fail-safe design, engineered design features, and procedures that minimize the consequences of DBAs. As part of defence-in-depth, pressure retaining components in any safety system are required to meet the highest design and quality standards. In summary, the baseline plant incorporates extensive defence-in-depth at Levels 1, 2 and 3.

The fourth level of defence-in-depth makes use of the additional inherent capacity and capability of station systems and also relies on many additional systems that are not normally credited in safety analysis for DBAs. They are used to mitigate the consequences of BDBAs, including severe accidents. Such accidents have a very low frequency due to the high reliability of the safety systems and other mitigating provisions. Level 4 provisions are generally backup process systems and as such have been designed such that their failure would not affect the control or safety systems. The recent addition of Emergency Mitigating Equipment supplements the previous Level 4 provisions.

Comprehensive on-site and off-site plans and new facilities and processes have been implemented for response to emergencies as the fifth level of defence. Significant improvements have been implemented in the fourth and fifth levels of defence, based on international OPEX since Pickering NGS Units 1,4 and 5-8 were put into service, as well as new requirements from the CNSC.

A detailed assessment of safety principles for each level based on the assignment in IAEA SRS-46 [8] is provided in Appendix D of this report. The information on the provisions for each of the safety principles is based on the current Pickering NGS design and operation and considers information from sources such as the PSR2 Safety Factor Reports, Probabilistic Safety Assessments and the Safety Reports. The assessments in Appendix D provide overall confirmation that effective and overlapping provisions are in place to meet the objectives of the safety principles.

An assessment based on a detailed review of the safety principles, some of which are applicable to multiple levels of defence-in-depth, is presented for each level of defence in the following sub-sections. The Defence-in-Depth Assessment also takes into consideration the proposed Resolution Plans for the Global Issues (Appendix F), Strengths (Appendix E) and the aggregate impact of the Acceptable Deviations (Appendix H).

18.3.1. Level 1 – Prevention of Abnormal Operation and Failures

The aim of the first level of defence is to prevent deviations from normal operation and failures.

The first level of defence requires high quality in the design and construction of the plant with barriers to prevent the occurrence of abnormal operating conditions. This is particularly important for the physical barriers surrounding the radioactive material in the Fuel. Safe, conservative operation of the plant by qualified staff and a continued focus on preventive maintenance ensures reliable functionality of plant equipment under normal operation and therefore prevents process upsets and failures.

18.3.1.1. Level 1 – Provisions and Barriers

There are 36 safety principles that apply to defence-in-depth Level 1, as shown in Appendix D. The appendix confirms that all of these principles are fulfilled by the Pickering NGS plant design, processes and management system. The safety principles in each of these three areas that are most relevant to Level 1 (prevention of abnormal operation and failures) in the context of extended operation of Pickering NGS are discussed briefly below.

With respect to the plant, the key safety principles that ensure that the design is adequate as a Level 1 barrier are:

- D-158 – General Basis for Design
- D-154 – Proven Technology
- D-195 – Reactor Core Integrity
- D-209 – Reactor Coolant System Integrity
- D-203 – Normal Heat Removal
- D-205 – Startup, Shutdown, and Low Power Operation
- D-188 – Radiation Protection in Design
- S-136 – External Factors Affecting the Plant

- M&C-249 – Achievement of Quality

The key safety principles related to processes that ensure that design requirements continue to be met, that supporting processes are in place to prevent SSC failures, and that fitness for service of SSCs is maintained through the operational life of the station are:

- O-296 Engineering and Technical Support of Operations
- D-150 Design Management
- M&C-246 Safety Evaluation of Design
- O-305 Maintenance, Testing and Inspection
- O-272 Conduct of Operations
- O-288 Normal Operating Procedures
- C-258 Validation of Operating and Functional Test Procedures
- O-284 Operational Limits and Conditions
- O-312 Quality Assurance in Operation

The key safety principles related to the management system and that support the effectiveness of the Level 1 barrier are:

- O-265 Organization, Responsibilities and Staffing
- O-299 Feedback of Operating Experience
- O-278 Training
- M&C-249 Achievement of Quality

Alignment with these key safety principles supports the adequacy of the Level 1 barrier at Pickering NGS. The following discussion describes the specific aspects of Pickering NGS that implement these and the other safety principles related to defence-in-depth Level 1.

At Pickering NGS, defence-in-depth Level 1 includes conservative design and high-quality construction and commissioning which provides a baseline confidence that any unexpected failure of SSCs and changes from normal operations are minimized and accidents are prevented.

Pickering NGS is designed and built to high quality standards, with critical safety functions that are diverse and physically separated from process control functions.

The use of redundant components, so that the failure of a single component does not cause system failure, leads to the use of two out of three voting logic, or channels, in many poised systems (systems available to operate if called on). This requires two of three separate instruments to fail unsafe before the system logic fails. This type of logic also permits on power testing, channel by channel, without impairing the functionality of the system and prevents spurious initiation of a system if one instrument or channel fails. Also, diversity of functions (e.g., process and neutronic measurements) for important control and safety systems is used, so that a common fault in one type of component cannot cause failure of the function. To the extent possible, equipment is designed to fail-safe on loss of electrical power (e.g., shutoff rods drop when they lose power to their clutches). Similarly, pneumatic instruments and components such as air-operated valves, have redundancies and are designed to be fail-safe to the extent possible. Self-actuating devices are employed where possible.

The Pickering NGS Heat Transport System is designed to avoid pressure boundary failure through high quality design and maintenance, provision of adequate pressure relief capability, and comprehensive leak detection capability. Confidence in the integrity of the pressure boundary is supported through appropriate assessments, and research and development.

These design features are described in Section 18.2.2. In addition, a comprehensive and effective Nuclear Management System has been developed and implemented which assures that systems, equipment, and activities are of the required quality throughout the operational life of the plant. The Management System, executed by an effective management and organization as described in Section 18.2.1, governs plant activities ranging from human performance, design and engineering, operations, maintenance, to waste management, and support nuclear safety at all levels of defence-in-depth. These programs are described in Section 18.2.3. These programs support fulfilling the safety requirements of defence-in-depth Level 1.

The safety systems SSCs are maintained within their design basis by N-PROG-MA-0026, *Equipment Reliability* [47] and N-PROG-MP-0008, *Integrated Aging Management* [48], which ensures the condition of critical equipment is understood and that required activities are in place to ensure the ongoing health of these components and systems. The program includes requirements for in-service inspections, maintenance, engineering assessment and confirmatory research and development. These processes provide for the timely detection and mitigation of aging effects in SSCs that impact plant safety and reliability. Regular preventive and predictive maintenance, inspection, testing and servicing of SSCs important to safety and reliability are conducted to maintain SSCs within their design basis.

Operational improvements are implemented continuously based on national and international OPEX in addition to improvements driven by the evolving regulatory requirements.

18.3.1.2. Level 1 – PSR2 Assessment

PSR2 assessments have demonstrated that the plant has been designed conservatively using the appropriate design codes and materials, design procedures, equipment qualification, control of component fabrication, plant construction and commissioning. The PSR2 review has confirmed that the physical plant conditions such as SSC design and construction are sound. Some PSR2 Gaps are associated with update of documentation or analysis to address specific modern codes and standards, and in many cases this work was already in progress. The Gaps do not identify any weaknesses in Level 1 that require design changes.

Level 1 provides the initial basis for protection against external and internal hazards. The review of Safety Factor 7 has confirmed the adequacy of protection of Pickering NGS against internal and external hazards, with account taken of plant design (including confirmation that analyses/methods address the condition of SSCs important to safety), site characteristics, and current analytical methods, safety standards and knowledge.

In parallel with the PSR2 review, an extensive set of Condition Assessments were completed. The Condition Assessments, along with current system and component health programs, provide the station with sufficient information on the condition of SSCs to mitigate aging effects throughout extended operation. The detailed assessment confirmed no component or system aging compromises the current design basis or design basis assumptions. For Special Safety Systems for both Units 1,4 and 5-8, all assessed components were found to support the extended operating period.

The review concluded that the condition of SSCs is well understood and that plant safety and reliability are maintained through a set of systematic and planned surveillance, testing, inspection and maintenance activities using best industry practices and OPEX. The PSR2 review has confirmed that programs continue to be improved in the areas of Condition Assessment, aging management, and obsolescence management.

The conditions of the Pickering NGS SSCs are tracked in System Health Reports and Component Health Reports that are aligned with industry best practices.

In addition, rigorous programs and processes are in place to control and verify design compliance to ensure that the plant is operated within the design basis and within the bounds of the SOE.

Strengths are identified that are related to programs that ensure operation within normal ranges and prevent failures. The Strengths considered most relevant to Level 1 (see Appendix E), which support plant design and physical plant condition thus allowing for the most effective prevention of failures are:

- Heat Removal Systems
- Electrical Power System
- Human Factors Engineering Program
- Environmental Qualification Program
- Effective Equipment Reliability Program
- System and Component Health Reporting
- Major Components Program
- Implementation of Safe Operating Envelope Program
- Deterministic Safety Analysis
- Operationalization of Probabilistic Safety Assessment
- Probabilistic Safety Assessment

Strengths are also identified in broader areas of plant operation. These are:

- Comprehensive Set of Performance Indicators
- Use of Operating Experience and Research Findings
- Radiation Exposure Performance

- Healthy Safety Culture
- Management
- Minimum Staff Complement
- Training
- Advanced Technology to Support Radiation Protection

Note that most of these Strengths are also relevant to some of the other defence-in-depth levels.

As per the assessment in Appendix H, the aggregate impact of Acceptable Deviations associated with defence-in-depth Level 1 is assessed to be very low.

18.3.1.3. Level 1 – Improvement Initiatives

The proposed Resolution Statements to address the Global Issues (Appendix F) are relevant and significant for sustaining and enhancing defence-in-depth Level 1, particularly for the proposed extended operation period.

The Global Issues associated with the most significant proposed Resolution Statements relevant to defence-in-depth Level 1 are:

- Fitness for Service for Major Components and other SSCs for extended operation [GI-1 to GI-4, GI-5, and GI-19]
- Condition Assessments in PSR2 scope [GI-8 and GI-43]

The objective of these initiatives is to enhance confidence in the fitness-for-service for the SSCs for the extended operation period.

18.3.1.4. Level 1 – Conclusions

The assessment has confirmed that at Pickering NGS, effective Level 1 barriers are ensured through the original conservative design supplemented by design improvements implemented since initial operation, comprehensive programs in place, including strong operating and maintenance programs to ensure continued fitness for service and operation within the design basis, and ongoing continuous improvements based on national and international OPEX and evolving regulatory requirements. Given the focus and priority placed on equipment reliability to address the findings in the areas of the equipment condition, this level of defence will continue to be strong and effective for Pickering NGS.

Pickering NGS Units 1,4 and 5-8 design and operation aligns with the 36 safety principles related to defence-in-depth Level 1.

18.3.2. Level 2 – Control of Abnormal Operation and Detection of Failures

Defence-in-depth Level 2 concerns the control of abnormal operation and the detection of failures; a strong Level 2 barrier entails control of power, protective systems, and other surveillance features.

Provisions and barriers are provided to prevent or to control abnormal process conditions, with an objective to bring the plant back to normal operating conditions. Level 2 design features control abnormal plant operation, incorporating inherent characteristics, with account taken for protection against mechanisms capable of causing further deterioration.

18.3.2.1. Level 2 – Provisions and Barriers

There are 32 safety principles that apply to defence-in-depth Level 2, as shown in Appendix D. All but one of these also apply to Level 1, and many also apply to other levels. Appendix D confirms that all of the Level 2 safety principles are fulfilled by the Pickering NGS plant design, processes and management system. The safety principles in each of these three areas that are most relevant to defence-in-depth Level 2 (control of abnormal operation and detection of failures) in the context of extended operation of Pickering NGS are discussed briefly below.

With respect to the plant, the key safety principles that ensure that transients are detected and effectively controlled are:

- D-205 – Startup, Shutdown, and Low Power Operation
- D-230 – Preservation of Control Capability
- D-164 – Plant Process Control Systems
- D-192 – Protection Against Power Transient Accidents

The key safety principles related to processes and that have with a strong focus on the Level 2 barrier are:

- D-227 – Monitoring of Plant Safety Status
- O-312 – Quality Assurance in Operation
- O-284 – Operational Limits and Conditions
- O-290 – Emergency Operating Procedures

The key safety principles related to the management system and that are most closely related to the Level 2 barrier are:

- O-299 – Feedback of Operating Experience
- O-278 – Training
- O-269 – Safety Review Procedures

Alignment with these key Level 2 safety principles supports the adequacy of the Level 2 barrier at Pickering NGS. The following discussion describes the specific aspects of Pickering NGS that implement these and the other safety principles related to defence-in-depth Level 2.

Level 2 defence-in-depth is achieved by detecting changes from normal operating conditions by the Reactor Regulating System, plant process control systems and the Special Safety Systems. The control systems in Pickering NGS maintain the reactor operating conditions within the normal operating range, and effectively respond to anticipated transients to avoid the need for safety system action. Reactor control in Pickering NGS has a high degree of immunity to process upsets, measurement failures, etc., due to extensive redundancy in control devices and process measurements. The ability to maintain control in the presence of partial system failures, combined with high reliability of the Dual Computer Control System, leads to a very high availability of the Reactor Regulating System, which controls reactor power. The Reactor Regulating System prevents or minimizes transients for all but the most serious postulated initiating events.

The normal method of shutting down the reactor is by means of the Reactor Regulating System. Digital computerized monitoring of parameters important to safety is used in the design of the Reactor Regulating System. During plant upsets or potentially undesirable operating conditions, the reactor is shut down or derated automatically by the reactor setback function of the Reactor Regulating System (Units 5-8 include setback and a similar stepback function). The computer system reduces the reactor power setpoint until either the setback signal clears or the power is reduced to a specified low value.

Pickering NGS has the appropriate indications and alarms in the Main Control Room (and in secondary areas should the Main Control Room become uninhabitable) to inform operations staff of mitigating system action and the status of key plant parameters such that initiating events can be controlled.

Provisions are in place for safe handling of the Fuel from its arrival at the plant through to the IFBs and dry storage. A lattice of natural uranium and light water cannot be made critical in any configuration. Hence, no criticality concern exists in handling new Fuel or in the IFB.

The extensive use of Main Control Room simulators for training and validation of system modifications to assess their impact on other systems and human-machine interfaces provides OPG with a safe means of testing and training operators to be prepared for the detection and control of postulated initiating events, thus strengthening the Level 2 barrier.

The PROL requires that operation of Pickering NGS shall conform to the Safety Report and, hence, the safety analysis. SOE Limits and Conditions define the envelope for operating in compliance with safety analysis. A well-established framework of operating procedures is in place which includes actions on the detection of equipment malfunctions to take action ensuring that the plant stays within a well-defined SOE. This contributes significantly as a Strength to this level.

SSCs important to plant safety and reliability are continuously monitored and frequently tested to assure that they operate within their SOE and comply with associated reliability and performance requirements.

18.3.2.2. Level 2 – PSR2 Assessment

Strengths are identified that are related to programs that control changes in operation and provide means to detect failures before they occur. These identified Strengths are common between Level 1 and Level 2, and some of the other levels. The Strengths considered relevant to Level 2 (see Appendix E), which support plant physical condition and operation thus preventing progression to DBAs are:

- Heat Removal Systems
- Electrical Power System
- Human Factors Engineering Program
- Environmental Qualification Program
- Effective Equipment Reliability Program
- Major Components Program
- Implementation of Safe Operating Envelope Program
- Deterministic Safety Analysis
- Operationalization of Probabilistic Safety Assessment
- Probabilistic Safety Assessment

Strengths are also identified in broader areas of plant operation. These are:

- Comprehensive Set of Performance Indicators
- Use of Operating Experience and Research Findings
- Radiation Exposure Performance
- Healthy Safety Culture
- Management
- Minimum Staff Complement Management
- Training
- Advanced Technology to Support Radiation Protection

Note that most of these Strengths are also relevant to some of the other defence-in-depth levels.

As per the assessment in Appendix H, the aggregate impact of Acceptable Deviations associated with defence-in-depth Level 2 is assessed to be very low.

18.3.2.3. Level 2 – Improvement Initiatives

The proposed Resolution Statements to address the Global Issues (Appendix F) are relevant and significant for sustaining and enhancing the safety requirements of defence-in-depth Level 2, particularly for the proposed extended operation period.

The Global Issues associated with the most significant proposed Resolution Statements are common between Levels 1 and 2 of defence-in-depth. These improvements, which are already in progress, are:

- Fitness for Service for Major Components and other SSCs for extended operation [GI-1 to GI-4, GI-5 and GI-19]
- Condition Assessments in PSR2 scope [GI-8 and GI-43]
- Safety Analysis [GI-24, GI-31 and GI-32]

The objective of these initiatives is to enhance confidence in the fitness-for-service for the SSCs and the ability of systems to control transients.

18.3.2.4. Level 2 – Conclusions

The assessment of defence-in-depth Level 2 concludes that the provisions in place are mature and robust and will be enhanced by completion of proposed Resolution Plans related to Level 2.

Pickering NGS Units 1,4 and 5-8 design and operation aligns with the 32 safety principles related to defence-in-depth Level 2.

18.3.3. Level 3 – Control of Accidents Within the Design Basis

The third level of defence consists of barriers to minimize the consequences of accidents should they occur by providing inherent safety features, fail-safe design, additional equipment (including Emergency Mitigating Equipment), and mitigating procedures.

A strong Level 3 barrier is evidenced by the design and the robustness of engineered safety features (e.g., Special Safety Systems) coupled with correspondingly robust operating procedures. The PSR2 and the safety principles review presented in Appendix D identify several effective barriers and Strengths in the areas of Design, Safety Analysis, OPEX, and Management.

18.3.3.1. Level 3 – Provisions and Barriers

There are 38 safety principles that apply to defence-in-depth Level 3, as shown in Appendix D. Many of these apply to Levels 1 and 2 as well, some also apply to Level 4, and five safety principles apply only to Level 3. Appendix D confirms that all of these principles are fulfilled by the Pickering NGS plant design, processes and management system. The safety principles in each of these three areas that are most relevant to defence-in-depth Level 3 (control of accidents within the design basis) in the context of extended operation of Pickering NGS are discussed briefly below.

With respect to the plant, the key safety principles that assure control of accidents within the design basis are:

- D-237 – Control of Accidents within the Design Basis (unique to Level 3)
- D-182 – Equipment Qualification (unique to Level 3)
- D-168 – Automatic Safety Systems (unique to Level 3)
- D-177 – Dependent Failures (unique to Level 3)
- D-200 – Automatic Shutdown Systems
- D-207 – Emergency Heat Removal
- D-217 – Confinement of Radioactive Material
- D-221 – Protection of Confinement Structure

With respect to processes related to ensuring that accidents within the design basis are controlled, the key safety principles are:

- D-174 – Reliability Targets (unique to Level 3)
- M&C-246 – Safety Evaluation of Design
- EP-339 – Assessment of Accident Consequences and Radiological Monitoring
- O-290 – Emergency Operating Procedures

The key safety principles related to the management system and that are most closely related to the Level 3 barrier are:

- O-299 – Feedback of Operating Experience
- O-278 – Training
- O-269 – Safety Review Procedures

Alignment with these key Level 3 safety principles supports the adequacy of the Level 3 barrier at Pickering NGS. The following discussion describes the specific aspects of Pickering NGS that implement these and the other safety principles related to defence-in-depth Level 3.

In Pickering NGS, accidents within the design basis are classified as single failure (i.e., a single process failure) and dual failure (i.e., a process failure combined with a coincidental impairment of a Special Safety System). Safety system impairments considered include an assumed failure of the system to perform its safety function.

Accidents within the design basis include events that have a potential of occurring during the lifetime of the plant, events that would be classified as DBAs, and some dual failures that are BDBAs in the CNSC REGDOC-2.4.1 [15] terminology.

Pickering NGS's Special Safety Systems together with their support systems are capable of controlling accidents within the design basis, and preventing them from progressing to a severe accident.

Analyses demonstrating the effectiveness of the automatic response of the Special Safety Systems are documented in Part 3 of the Pickering 1-4 and Pickering 5-8 Safety Reports [68], [69]. Safety analyses documented in Part 3, Appendix 3 of the Pickering 1-4 and Pickering 5-8 Safety Reports demonstrate the effectiveness of the Shutdown Systems in mitigating accidents.

Unavailability and PSA models are used during the design of modifications to the plant to confirm that the systems meet their system reliability requirements. The models use component failure rates and test frequencies to arrive at predicted system unavailability. During operation, component fault data are collected, and predicted future unavailability is recalculated and reported to the CNSC on a yearly basis for Systems Important to Safety, using this actual component experience. Pickering NGS has highly reliable Shutdown Systems for safety purposes that are designed to be independent of the equipment and processes used to control the reactor power and that are poised at all times during at-power operation.

Pickering units have multiple heat removal systems of adequate capacity. Together with their support systems, these systems ensure that heat generated in the Fuel is transferred to the atmosphere or the lake under normal operating and shutdown/outage conditions, as well as in response to DBAs. These systems are:

- Steam Generators (boilers) supplied by inventory from normal or auxiliary feed water.
- Shutdown Cooling Heat Exchangers supplied by normal or Emergency High Pressure Service Water.
- Emergency heat removal with High Pressure ECI and ECI recovery, with Reactor Building Air Coolers.
- For events involving a loss of boiler inventory, in the short term, the Boiler Emergency Cooling System provides water to both Pickering 1,4 and Pickering 5-8 for reactor decay heat removal by the boilers for accident situations initiated by or leading to failure of the normal feedwater supply.
- For long-term cooling, the Emergency Boiler Water System is designed to provide emergency water to the boilers of Units 1,4.
- In Units 5-8, the Emergency Water System is a seismically qualified system supplying long-term emergency makeup to the boilers, Heat Transport System, ECI recovery heat exchangers, Containment air coolers and the Calandria.

The reactors are equipped with multiple sources of electrical power to ensure that controls and equipment important to safe operation are available. The sources of power are: the grid (off-site power), unit generator, other unit generators (Site Electrical System), Standby Generators, gas turbine/generator sets (Emergency Power System for Units 5-8), Combustion Turbine Unit driven generators (Auxiliary Power System) and batteries.

Standby power from six independent gas turbine driven Standby Generators for Units 1,4 and six for Units 5-8 is dedicated to those loads that are required for the safe shutdown of the reactor and heat sink/cooling of the Fuel core.

The Pickering NGS Units 1,4 and 5-8 designs include protection against common cause events; the design includes provisions to prevent the loss of safety functions due to damage to multiple SSCs. For Units 5-8, redundant equipment and circuits are separated and grouped (Group 1 and Group 2) to ensure the safety of the station following a common mode event. Each group is capable, independently of the other group, of safely shutting down the reactor, cooling the Fuel, and providing the operator with indications of system conditions. Units 1,4 systems have been either qualified or retrofitted to function as required for a given common mode event by ensuring effective separation and diversity. Hazard assessments have been performed that confirm the capability of the design to perform the required safety functions following postulated common mode events.

The seismically-qualified Emergency Power System for Units 5-8 supplies power to a specific portion of the Safety-Related Systems in the station. The purpose of the Emergency Power System is to independently perform the critical reactor safety functions, i.e., Control, Cool and Contain, on total loss of Group 1 distribution systems.

In addition, a third Emergency Power Generator set, consisting of three diesel generators capable of delivering a total of 2.5 MW, has been added to Units 5-8 to provide additional redundancy in the Emergency Power System.

The Auxiliary Power System is a back-up power supply system that supplies power to important Group 1 Class IV loads following a sustained total loss of Class IV power across Pickering NGS following a failure of the Bulk Electrical System. The system performs this function by supplying power to the Site Electrical System.

The ECI System is capable of restoring and maintaining fuel cooling following a LOCA.

One of the proven safety features is the ability to cool the Fuel through natural circulation that occurs in the Heat Transport System when forced circulation is lost.

The Pickering NGS Containment System is designed to retain radioactive material that might be released from the Fuel during an accident, and Containment effectiveness is demonstrated by safety analyses showing that public dose meets the applicable regulatory limits for the full range of accidents considered in the design.

Operating Manuals and Abnormal Incident Manuals are designed to allow the operator to respond to events. If actions identified in Operating Manuals and Abnormal Incident Manuals are unsuccessful in terminating the accident progression, actions will be taken per the Emergency Mitigating Equipment Guidelines to prevent the accident from progressing to a severe accident. Also, post-accident monitoring capability of the critical safety parameters is available. By monitoring critical safety parameters, and following critical safety parameter restoration procedures via field actions, it is possible to maintain the Control, Cool, Contain and Monitor safety functions, including from locations external to the Main Control Room.

A Hydrogen Ignition System is provided to safely combine any hydrogen (or deuterium) gases generated in Containment following DBAs that may produce hydrogen. The system is capable of addressing very low concentrations of hydrogen in air/steam mixtures, thus preventing the occurrence of high concentrations of hydrogen in Containment. In addition, the installation of Passive Auto-catalytic Recombiners provides additional redundancy to the Hydrogen Ignition System for control of hydrogen in Containment and thus ensures Containment integrity, therefore strengthening the capability of Pickering NGS to control accidents within the design basis. The Fukushima review and the actions to address events including the unlikely event of an extended loss of off-site power have further strengthened the robustness of the plant.

18.3.3.2. Level 3 – PSR2 Assessment

Confirmation of the effectiveness of the Level 3 barriers has been significantly enhanced with the completion of the CNSC S-294 [70] compliant PSA, which included internal hazards fire and flooding and external hazards seismic and high winds. This will be further enhanced by completion of the implementation strategy for CNSC REGDOC-2.4.2 [71]. The effectiveness of Level 3 barriers is also confirmed by conformance with CNSC S-98 [72] for specifying reliability targets for systems important to safety at Pickering NGS and monitoring the system reliability performance against those targets.

Strengths are identified that are related to programs that control accidents within the design basis. The Strengths considered most relevant to Level 3 (see Appendix E) and other levels, which support the plant design in meeting requirements for DBAs and for preventing progression to BDBA, are:

- Heat Removal Systems
- Electrical Power System
- Human Factors Engineering Program
- Environmental Qualification Program
- Effective Equipment Reliability Program
- Major Components Program
- Implementation of Safe Operating Envelope Program
- Deterministic Safety Analysis
- Operationalization of Probabilistic Safety Assessment
- Probabilistic Safety Assessment

Strengths are also identified in broader areas of plant operation. These are:

- Comprehensive Set of Performance Indicators
- Use of Operating Experience and Research Findings
- Radiation Exposure Performance
- Healthy Safety Culture

- Management
- Effective Training Programs
- Minimum Staff Complement

As per the assessment in Appendix H, the aggregate impact of Acceptable Deviations associated with defence-in-depth Level 3 is assessed to be very low.

18.3.3.3. Level 3 – Improvement Initiatives

The proposed Resolution Statements to address the Global Issues (Appendix F) are relevant for sustaining and enhancing the safety requirements of defence-in-depth Level 3.

The Global Issues associated with the most significant proposed Resolution Statements relevant to Level 3 are:

- PSA Risk Reduction Plan [GI-27]
- Buried Piping Risk [GI-9]
- Safety Analysis [GI-24, GI-31 and GI-32]

18.3.3.4. Level 3 – Conclusions

The PSR2 assessments and the review of safety principles show an effective Level 3 barrier. Adequate and effective provisions for the control of accidents within the design basis are provided at Pickering NGS. Operators have indications and alarms as well as the capability to perform actions from the Main Control Room for this purpose.

The review confirms that the Pickering NGS has strong Level 3 barriers due to the high quality of the design that includes extensive mitigating provisions, comprehensive accident management procedures, and a robust set of safety analyses.

18.3.4. Level 4 – Control of Severe Plant Conditions

Defence-in-depth Level 4 concerns the control of severe plant conditions, and includes the prevention of accident progression and the mitigation of severe consequences resulting from initial accidents. A strong Level 4 barrier is evidenced by strong complementary measures coupled with robust accident management strategies.

18.3.4.1. Level 4 – Provisions and Barriers

There are 34 safety principles that apply to defence-in-depth Level 4, as shown in Appendix D. Many apply to Levels 1, 2 and 3 as well. Some also apply to Level 5. Three safety principles apply only to Level 4. Appendix D confirms that all of these principles are fulfilled by the Pickering NGS plant design, processes and management system. The safety principles in each of these three areas that are most relevant to Level 4 (control of severe plant conditions) in the context of extended operation of Pickering NGS are discussed briefly below.

With respect to the plant, the key safety principles that are relevant to Level 4 are:

- AM-326 – Engineered Features for Accident Management (unique to Level 4)
- EP-336 – Emergency Response Facilities
- D-233 – Station Blackout
- D-221 – Protection of Confinement Structure
- D-207 – Emergency Heat Removal
- D-227 – Monitoring of Plant Safety Status

With respect to processes related to control of severe plant conditions, the key safety principles are:

- AM-318 – Strategy for Accident Management (unique to Level 4)
- AM-323 – Training and Procedures for Accident Management (unique to Level 4)
- O-290 – Emergency Operating Procedures
- EP-333 – Emergency Plans
- EP-339 – Assessment of Accident Consequences and Radiological Monitoring

The key safety principles related to the management system and that are most closely related to the Level 4 barrier are:

- O-299 – Feedback of Operating Experience
- O-278 – Training
- O-269 – Safety Review Procedures

Safety Principle O-299, Feedback of Operating Experience, is particularly important with respect to lessons learned from the 2011 Fukushima accident.

Alignment with these key Level 4 safety principles supports the adequacy of the Level 4 barrier at Pickering NGS. The following discussion describes the specific aspects of Pickering NGS that implement these and the other safety principles related to defence-in-depth Level 4.

Pickering NGS Units 1,4 and 5-8 have complementary design features for BDBAs. Some of these design features include redundant power systems, design adequacy for internal and external hazards, and hydrogen igniters and Passive Auto-catalytic Recombiners. If actions identified in Operating Manuals and Abnormal Incident Manuals are unsuccessful in terminating the accident progression, actions will be taken per the Emergency Mitigating Equipment Guidelines to prevent the accident from progressing to a severe accident.

Pickering NGS has implemented Severe Accident Management Guidelines for mitigating severe accident progression and protecting Containment. Severe Accident Management Guidelines are a set of written guidance to implement strategies should a BDBA progress to a severe accident. The goals of Severe Accident Management Guidelines are to terminate progression of core damage, if possible, by restoring cooling, and to protect Containment. The Severe Accident Management Guidelines aid in identifying longer-term actions that are required to address post-accident conditions once the station has been returned to a controlled, stable state.

In terms of maintenance of fuel cooling, a key line of defence for BDBAs is Emergency Boiler Makeup using Emergency Mitigating Equipment. An additional line of defence is Emergency Mitigating Equipment to provide water makeup to the Moderator. These features are capable of limiting core damage and support Containment pressure control for most BDBAs.

Emergency Mitigating Equipment has been provided for an additional makeup water supply for accidents beyond the design basis. Portable diesel-powered pumps can be deployed to provide cooling water make-up to the secondary side of the boilers, to the Heat Transport System and to the Moderator. Additional Fukushima Project design modifications have been installed to enhance water makeup/cooling capability for the IFBs.

In addition, implementation of Phase 2 Emergency Mitigating Equipment modifications is in progress. Phase 2 Emergency Mitigating Equipment includes restoration of power to key station equipment to support core cooling and monitoring and to Containment coolers to support control of Containment pressure following BDBAs.

Particular importance is placed on protecting Containment. A strong Level 4 barrier is evidenced by a robust Containment design as well as use of complementary design features and procedures to halt accident progression and mitigate the consequences of Beyond Design Basis conditions.

A Hydrogen Ignition System is provided to safely combine hydrogen (or deuterium) gases generated in Containment. The system is capable of addressing very low concentrations of hydrogen in air/steam mixtures, thus preventing the occurrence of high concentrations of hydrogen in Containment. In addition, Passive Auto-catalytic Recombiners have been installed to control Containment hydrogen levels at reduced hydrogen generation rates, and therefore eliminate reliance on the Hydrogen Ignition System in the longer term.

Emergency planning also encompasses many of the concepts of the Level 4 barrier. A mature emergency response infrastructure is in place, and the requisite qualified staff and expertise are maintained. As well, a *Mutual Aid Agreement for Nuclear Emergency Support* [67] among emergency support organizations from the Canadian nuclear operators has been established for inter-utility emergency support. This aspect of Level 4 is identified as a Strength.

18.3.4.2. Level 4 – PSR2 Assessment

The PSR2 review confirmed that committed Fukushima Action Items that control the progression and consequences of severe accidents have been or are being implemented, including:

- Installation of Passive Auto-catalytic Recombiners on all units (completed)
- Addition of Emergency Mitigating Equipment including portable diesel pumps and diesel generators (completed)
- Enhancements to water makeup/cooling capability for the IFBs (completed)
- Additional flood barriers installed around the Pickering A Standby Generator Fuel Forwarding Pump house (completed)
- Enhancements to Severe Accident Management Guidelines (completed)
- Additional Phase 2 Emergency Mitigating Equipment provisions (in progress)

The review in the Safety Factor 13 Report has confirmed that OPG Nuclear has: a) adequate plans, staff, facilities and equipment in place for dealing with a full range of emergencies, and b) there is regular emergency training and exercises, and adequate arrangements are in place for effective interaction and coordination with local and national authorities.

Strengths are identified that are related to programs that control accidents within and beyond the design basis. The Strengths considered most relevant to Level 4 (see Appendix E), which support plant design improvements thus allowing for the most effective control of severe accident conditions are:

- Implementation of Fukushima Action Items
- Use of Operating Experience and Research Findings
- Emergency Management

As per the assessment in Appendix H, the aggregate impact of Acceptable Deviations associated with defence-in-depth Level 4 is assessed to be very low.

18.3.4.3. Level 4 – Improvement Initiatives

The proposed Resolution Statements to address the Global Issues (Appendix F) are relevant for sustaining and enhancing the safety requirements of defence-in-depth Level 4.

The Global Issues associated with the most significant proposed Resolution Statements relevant to defence-in-depth Level 4 are:

- PSA Risk Resolution Plan [GI-27]
- Implementation of Emergency Mitigating Equipment [GI-40]

18.3.4.4. Level 4 – Conclusions

The measures considered at the first three levels will ensure maintenance of the structural integrity of the core and limit potential radiation hazards for members of the public. The PSR2 assessments and the review of safety principles show that additional design features and procedural provisions are in place and are effective for defence-in-depth Level 4.

The complete implementation of Severe Accident Management Guidelines and the OPEX from the 2011 Fukushima accident has also significantly strengthened this level. OPG is continuing to implement enhancements, such as the Phase 2 Emergency Mitigating Equipment, that will further strengthen defence-in-depth Level 4.

18.3.5. Level 5 – Mitigation of Radiological Consequences

Defence-in-depth Level 5 concerns the mitigation of radiological consequences of releases of radioactive material; a strong barrier indicates a robust emergency response program.

18.3.5.1. Level 5 – Provisions and Barriers

As shown in Appendix D, seven safety principles apply to defence-in-depth Level 5, and of these, three apply to all other levels. One safety principle also applies to Levels 3 and 4, two apply to Levels 4 and 5 and one applies only to Level 5. Appendix D confirms that all of these safety principles are fulfilled. The safety principles that apply to defence-in-depth Level 5 (mitigation of radiological consequences of significant releases of radioactive materials) are:

- S-140 – Feasibility of Emergency Plans (unique to Level 5)
- EP-333 – Emergency Plans
- EP-336 – Emergency Response Facilities
- EP-339 – Assessment of Accident Consequences and Radiological Monitoring
- S-138 – Radiological Impact on the Public and the Local Environment
- O-265 – Organization, Responsibilities and Training
- O-296 – Engineering and Technical Support of Operations

Alignment with these key Level 5 safety principles supports the adequacy of the Level 5 barrier at Pickering NGS. The following discussion describes the specific aspects of Pickering NGS that implement the safety principles related to Level 5.

In the event of an emergency, there are permanent on-site and off-site facilities appropriately equipped for effective emergency response. During the initial emergency phase, Main Control Room staff perform the assessment of plant status. Where possible, the Main Control Room staff also identify damage to plant equipment. Appropriate plant procedures are used and Main Control Room staff initiate an immediate operations response to move towards taking the plant to a safe and stable configuration. The Main Control Room team utilizes resources of the on-site Emergency Operations Centre to mobilize and deploy the necessary emergency teams. Main Control Room staff will seek, as appropriate, consultative, technical and resource assistance from the Site Management Centre who will in turn seek, as appropriate, assistance from the Corporate Emergency Operations Facility. During the response phase, the Main Control Room and Site Management Centre staff will, as a continuing action, evaluate the implementation of the emergency mitigation strategy and modify it as necessary.

The Provincial Emergency Operations Centre, located at the Ministry of Community Safety and Correctional Services in Toronto, is the provincial facility and organization that directs off-site emergency response operations.

Additional off-site emergency response facilities include:

- Durham Region Reception Centres and Emergency Worker Centres
- City of Toronto, Municipal Emergency Operations Centre

OPG Program N-PROG-RA-0001, *Consolidated Nuclear Emergency Plan* [73] provides a written basis that documents concepts, roles and resources required by OPG Nuclear to implement and maintain its emergency response capability to protect the public, employees and the environment in the event of a nuclear emergency. The *Consolidated Nuclear Emergency Plan* [73] defines a nuclear emergency as an emergency which poses an actual or potential hazard to public health and property or the environment from ionizing radiation, whose source is a major nuclear installation. Emergency plans have been prepared under the *Consolidated Nuclear Emergency Plan* [73], and emergency preparedness drills and exercises are mandated and are carried out for Pickering NGS.

The Provincial Nuclear Emergency Response Plan [74] requires Pickering NGS to procure adequate quantities of stable iodine tablets for their Primary Zone population. Potassium Iodide (KI) tablets have been distributed to residences and businesses in the Primary Zone. Designated Primary Zone municipalities are also required to establish and maintain a public alerting system in accordance with the Provincial Nuclear Emergency Response Plan.

The adequacy of the response and mitigation strategies that have been developed is demonstrated primarily through drills and exercises. On an annual basis, OPG's Emergency Preparedness Department assesses the Emergency Response Organization performance and reviews all drill and exercise related corrective actions to monitor status and ensure completeness. As part of the lessons learned from the 2011 Fukushima accident, Beyond Design Basis Emergency Response drills and exercises have been incorporated into the plans.

Integrated and partial emergency exercises have been conducted at Pickering NGS to confirm the satisfactory function of the emergency organization and its equipment.

18.3.5.2. Level 5 – PSR2 Assessment

Both the PSR2 and the safety principles review confirm that OPG has the following significant Strength related to defence-in-depth Level 5:

- Emergency Management.

The program is well established and coordinated both within and external to OPG.

As per the assessment in Appendix H, there are no Acceptable Deviations associated with defence-in-depth Level 5, so there is no impact of Acceptable Deviations on Level 5.

18.3.5.3. Level 5 – Improvement Initiatives

Completion of the Emergency Response Projection enhancements [GI-26] is relevant for sustaining and enhancing the safety requirements of defence-in-depth Level 5.

18.3.5.4. Level 5 – Conclusions

The coordinated emergency response capability of the various response organizations and the implementation of OPEX from the 2011 Fukushima accident support the strength of the Level 5 defence-in-depth provisions. Implementation of the planned improvement initiatives will further enhance the barriers for Level 5 at Pickering NGS.

18.4. Defence-in-Depth Assessment Conclusions

The detailed review of provisions for each level of defence presented above and in Appendix D shows that Pickering NGS Units 1,4 and 5-8 design and operation have adequate and effective barriers in all applicable levels of defence-in-depth and that significant improvements have been implemented since the plant was put into service.

The comprehensiveness of the assessment is assured by assessing each of the safety principles, which are supported by multiple and overlapping provisions, for each level of defence-in-depth. Furthermore, each defence-in-depth level is supported by multiple safety principles providing a second layer of overlap of provisions across levels of defence-in-depth.

The adequacy of these provisions has also been confirmed by the comprehensive PSAs. The Pickering Units 1,4 and 5-8 PSAs demonstrate that the overall plant design has a Core Damage Frequency and Large Release Frequency within the specified risk-based Safety Goals, indicating robustness in the design, and reliable equipment that is capable of responding effectively to accident scenarios. The defence-in-depth will be further strengthened with the implementation of the proposed Resolution Plans.

Implementation of lessons learned from the 2011 Fukushima accident, and installation of additional Emergency Mitigating Equipment for BDBAs has added further capability to the defence-in-depth. The development of Beyond Design Basis Emergency Mitigating Equipment Guidelines and enhancement to the Severe Accident Management Guidelines, to implement the requirements of OPG Standard N-STD-MP-0019, *Beyond Design Basis Accident Management* [75], have resulted in Pickering NGS strengthening its capability to mitigate and respond to low probability BDBAs. The continued implementation of the remaining post-Fukushima initiatives underway at Pickering will provide additional robustness to an already strong program. Implementation of the proposed Resolution Plans will further enhance the defence-in-depth for extended operation.

19. Conclusion of the Assessment of Overall Acceptability of Operation of the Plant

The Global Assessment demonstrates that Pickering NGS will operate safely during the extended operating period. In addition, activities are in progress and planned that will further enhance safe plant operation. The justification for this conclusion is based on the following:

Current Plant State:

i) The Pickering Station Leadership Team has effectively aligned the organization to significantly improve performance in a number of key focus areas. Station performance improvement has been recognized through industry reviews. The plant is safe, and is operated safely.

ii) OPG has comprehensive programs in place to ensure the condition of SSCs important to safety at Pickering 1,4 and Pickering 5-8 is well understood, to assess the level of fitness for service, and to effectively take action to maintain good plant condition. This has led to continuous improvement in the condition of the plant, and plant performance.

iii) OPG has made significant improvements to the Pickering plant design and processes. The plant design enhancements, discussed in Section 18, together with the process enhancements, closely align the plant with safety-significant requirements of modern codes and standards (which in some cases are beyond current requirements), and enhance defence-in-depth. In particular, enhancements made in response to the 2011 Fukushima accident have reduced, and will further reduce, the risk associated with BDBAs.

iv) Design and operation of the plant meet the current deterministic safety analysis dose limits, and processes are in place to ensure the safety analysis accounts for any additional aging effects associated with extended operation. The Probabilistic Safety Assessment shows that the OPG risk-based Safety Goals for Core Damage Frequency and Large Release Frequency are met. Initiatives have been proposed to further enhance the margins to these goals.

v) Radiological dose performance and environmental impact performance are significantly better than regulatory limits. Programs in place ensure the ongoing effectiveness of the radiological protection of workers, the public and the environment.

Results of the Periodic Safety Review:

i) The Global Assessment identifies 24 Strengths (refer to Section 16), indicating that Pickering NGS is well aligned with modern codes, standards and practices in key areas.

ii) The Global Assessment identifies 51 Global Issues (refer to Section 11). Proposed Resolution Plans for Global Issues are developed, and many are in progress to further enhance safety (refer to Section 13), including enhancements to further reduce the risk associated with BDBAs. Most of the proposed Global Issue Resolution Plan actions reflect existing work programs and plans at the station. In particular, for the Global

Issues of highest safety significance (i.e., fitness for service to cover the extended operating period), OPG was already fully aware of these issues and is actively working on addressing them for the extended operating period. None of the Global Issues identify a safety concern that requires additional planned or urgent action to be taken. The proposed Resolution Plans will be supported by specific actions in the Integrated Implementation Plan.

iii) The Global Issues of highest safety significance pertain to fitness for service of SSCs important to safety over the extended operating period. Units will be operated only if fitness for service of SSCs important to safety is assured. OPG has comprehensive programs in place to ensure the condition of SSCs important to safety is well understood, to assess the level of fitness for service, and to effectively take action to maintain good plant condition. The proposed Resolution Plans for these Global Issues will ensure the ongoing fitness for service of SSCs for the operational life of the plant, and these plans are actively being progressed.

iv) The Global Assessment includes a Resolution Plan that proposes the investigation and implementation of design, operational, and/or analytical options to further enhance margins to risk-based Administrative Safety Goals.

v) The assessment of Acceptable Deviations (refer to Appendix H) confirms there is no impact on the conclusion of the Global Assessment, either individually or in aggregate.

vi) The assessment of defence-in-depth of the plant (refer to Section 18) includes a detailed review and confirmation of the adequacy of the provisions for each level of defence. This is based on an assessment of how the related safety principles for each level of defence-in-depth are met, taking into account the plant design, the ongoing operations and maintenance activities at the plant, the identified Strengths, as well as the proposed enhancements identified in the Global Assessment process. The assessment also accounts for the aggregate effect of Acceptable Deviations. The Defence-in-Depth Assessment shows that Pickering Units 1,4 and Pickering Units 5-8 design and operation have adequate and effective barriers in all levels of defence-in-depth.

vii) OPG's organizational structure and management system provides the requisite processes, tools, resources and oversight that will ensure continued safe operation of the plant.

In summary, the current plant design, operation, processes and management system will ensure continued safe operation of Pickering 1,4 and Pickering 5-8 both in the short term, and for extended operation. OPG and the Pickering Station Leadership Team are committed to investing in the plant, and focusing the organization to strive for continued improvement in the plant condition, operation and performance.

Appendix A – Modern Laws, Regulations, Codes and Standards Assessed in PSR2

The modern Laws, Regulations, Codes and Standards in the PSR2 Assessment Basis (refer to Section 2.6.2 of the PSR2 Basis Document [P-REP-03680-00001-R002, *Pickering NGS Periodic Safety Review 2 (PSR2) Basis Document*, June 2016]) are listed in this appendix. The freeze date was January 15, 2016. Where a document was issued in January 2016 but the effective date is unknown, it was considered to have been issued prior to the freeze date. The process for selecting PSR2 Laws, Regulations, Codes and Standards is described in Section D.1.0 of the PSR2 Basis Document [P-REP-03680-00001-R002, *Pickering NGS Periodic Safety Review 2 (PSR2) Basis Document*, June 2016]. The assessments were performed on the safety significant requirements.

Three types of assessments were considered for PSR2:

- Clause-by-Clause review (C): New Laws, Regulations, Codes and Standards referenced in Pickering PROL 48.02/2018 (listed in Appendix C of the Licence Conditions Handbook) were subjected to a clause-by-clause type review. In a clause-by-clause review, conformance with individual clauses is demonstrated by supporting evidence stating whether the requirements stipulated in the requirement document are met.
- High Level review (HL): New Laws, Regulations, Codes and Standards not referenced in Pickering PROL 48.02/2018 but which are in the PSR2 Assessment Basis were subjected to a high level review. In a high level review, the degree of conformance with clauses or groups of clauses in the Law, Regulation, Code or Standard is demonstrated by supporting evidence stating whether the intent of the requirements stipulated in the requirement document is met.
- Incremental review (I): For Laws, Regulations, Codes and Standards that have been reviewed in PSR1 but have had revisions since the last review, a topical review of the changes was performed.

The majority of modern Laws, Regulations, Codes and Standards in the PSR2 Assessment Basis were subjected to an incremental review as part of PSR2. The following table lists the modern Laws, Regulations, Codes and Standards considered in PSR2 and shows the Safety Factor Reports that contain the corresponding assessments, along with the PSR2 Gaps related to each modern Law, Regulation, Code or Standard.

[31] A gap analysis for N290.7-14 was completed by OPG and satisfies the intent of the PSR2 High Level Review. For reasons of security and confidentiality, the findings of the gap analysis are not discussed in this Global Assessment Report.

[32] The assessment of the National Fire Code of Canada in [P-REP-03680-00029 R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 1, 5, 6, and 7*, March 3, 2017] did not create a new SF1 Gap since the same gap is already identified as a COP Review Gap in [P-REP-03680-00024 R000, *Pickering 5-8 Continued Operations Plan Review in Support of PNGS Periodic Safety Review 2*, January 17, 2017].

Appendix B – Global Issues and Proposed Resolution Plans

B.1. GI-1 Fitness for Service for Fuel Channels

SECTION 1 - GI-1 GLOBAL ISSUE SUMMARY					
The goal of GI-1, Fitness for Service for Fuel Channels, is to ensure that Fuel Channels remain fit for service for the extended operating period. This Global Issue comprises four proposed Resolution Statements addressing nine Gaps: three SF2 review task Gaps, one SF4 code review Gap [CSA N285.8-15], one COP Review Gap, three COP Additional Gaps and one SF2 Additional Gap. GI-1 is Safety Significance Level 1 based on deterministic and probabilistic defence-in-depth considerations as well as plant operability considerations. OPG has in place robust FFS programs for major components, such as Fuel Channels, and will not operate a reactor unit unless there is high confidence in demonstrating the FFS of these major components and continued safe operation of Pickering NGS.					
Safety Significance Level:	1	**Category:**	Programmatic, Engineering, Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-1 ASSOCIATED GAPS	
SF2-1	Fitness for Service for Fuel Channels has not been demonstrated for station operation to 2028[33]. ***Review Task #1 Actual Condition of SSCs*** **Associated Resolutions:** GI-1-RS2, GI-1-RS4
SF2-2	OPG does not have approval to operate beyond the current Licence limit of 247,000 Effective Full Power Hours (EFPH) for Fuel Channels. ***Review Task #1 Actual Condition of SSCs*** **Associated Resolutions:** GI-1-RS4
SF2-3	The Fuel Channels LCMP has not been formally updated to address extended station operation to 2028[33]. ***Review Task #1 Actual Condition of SSCs***

[33] As noted in the PSR2 Basis Document [P-REP-03680-00001-R002, *Pickering NGS Periodic Safety Review 2 (PSR2) Basis Document*, June 2016], the current planning basis for Pickering NGS is that Pickering NGS units will operate until the end of 2024. To align with the anticipated expiry date of the next PROL, for the purposes of PSR2 only the period of operation of Pickering NGS units is extended until the end of 2028.

SECTION 2 - GI-1 ASSOCIATED GAPS	
	Associated Resolutions: GI-1-RS2, GI-1-RS3
SF4-16	For the Pickering B ISR, no clause-by-clause review of CSA N285.8 was conducted on the basis that the pressure tubes will be replaced during the refurbishment outage for Pickering Units 5-8, and the condition of these components is well understood and managed through their own specific, detailed life cycle plans and fitness-for-service criteria. However, in November 2015, OPG issued Plan N-REP-31100-10061 R002 for Pickering NGS compliance with pressure tube in-service evaluation requirements in CSA N285.8-15. OPG had submitted a previous compliance plan for the long term use of the 2010 edition of CSA N285.8 and this compliance plan was accepted by the CNSC. The compliance plan was revised to document OPG's compliance to the 2015 edition of CSA N285.8. Since OPG has committed to fulfillment of the commitments in N-REP-31100-10061 R002, successful fulfillment by OPG of the commitments in the compliance plan is required for Pickering operation past 2020. This is therefore a Gap for Pickering PSR2. In particular, the significant changes to CSA N285.8-15 per the CSA Impact Statement will need to be reflected in Pickering procedures, including: • Implementation of statistically based fatigue crack initiation evaluation curves for axial flaws (Clauses D.4.2, D.4.3, and D.3.6); • Implementation of closed-form engineering relation for threshold peak stress for Delayed Hydride Cracking initiation (Clauses D.5 and 5.4.3.4); • Implementation of statistically based threshold relation for peak stress for crack initiation due to hydrided region overloads (Clause D.5); • Implementation of new fracture toughness models for axial through-wall flaws (Clause D.13.2); and • Implementation of Methods 1 and 2 Probabilistic Leak-Before-Break (Clauses 3.1, 7.3 and 7.4) ***Code Review N285.8-15*** **Associated Resolutions:** GI-1-RS1
COP-1	The probabilistic LBB assessments have not yet been fully completed for the entire extended operating period, as work is being performed to demonstrate fitness for service for the pressure tubes in a staged approach. ***Pickering PSR2 Gap COP-1*** **Associated Resolutions:** GI-1-RS1, GI-1-RS4
COP-AG2	Determine if reconfiguration of P7 & P8 Fuel Channels is required prior to 238k EFPH and if necessary, schedule reconfiguration for completion prior to 238k EFPH in the Fuel Channel Life Cycle Management Plan. ***Pickering PSR2 Gap formerly named COP-28*** **Associated Resolutions:** GI-1-RS4

SECTION 2 - GI-1 ASSOCIATED GAPS	
COP-AG3	Assess the susceptible flaws present in the inspected pressure tubes for crack initiation induced by Hydrided Region Overload for applicable loading conditions. ***Pickering PSR2 Gap formerly named COP-29*** **Associated Resolutions:** GI-1-RS1
COP-AG4	Assess and demonstrate the structural integrity of Zr-Nb-Cu loose fitting garter springs for operation during the PSR2 period. ***Pickering PSR2 Gap formerly named COP-30*** **Associated Resolutions:** GI-1-RS4
SF2-AG1	An SF2 Gap related to updating the Fuel Channels Life Cycle Management Plan as well as the Technical Basis used in the Fuel Channels Life Cycle Management Plan, documentation on mitigating actions such as R&D and extent of condition of each aging degradation mechanism, and the potential for CT/LISS contact prior to 2024 due to fuel channel sag, was identified in [P-CORR-00531-05099, e-Doc 5295534, July 12, 2017]. The associated resolution addresses Items (a) and (b) of the reference. Item (c) is addressed by GI-4. **Associated Resolutions:** GI-1-RS4

SECTION 3 - GI-1 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains nine Gaps (three SF2 Gaps, one SF4 Gap, one COP Review Gap, three COP Additional Gaps and one SF2 Additional Gap) that are related to Fitness for Service (FFS), the Life Cycle Management Plan (LCMP) and life extension approval for Fuel Channels.

OPG has well-established programmatic controls to demonstrate FFS for Fuel Channels. FFS is demonstrated through application of the OPG Integrated Aging Management Program (IAMP) [N-PROG-MP-0008-R006B, *Integrated Aging Management*, April 29, 2016], which is compliant with CNSC Regulatory Documents REGDOC-2.6.3 *Aging Management* (which superseded RD-334 *Aging Management for Nuclear Power Plants*), and REGDOC-2.3.3 *Periodic Safety Reviews* (which superseded RD-360 *Life Extension of Nuclear Power Plants*). Integrated Aging Management is based on understanding of the component and system design, materials, degradation mechanisms and operating environment. IAMP provides a Plan – Do – Check – Act cycle of activities to support continued fitness for service throughout the planned service life of the component. Application of the IAMP process, via the OPG Major Components Program [N-PROG-MA-0025-R002, *Major Components*, March 25, 2015], establishes a basis for demonstration of FFS for the Fuel Channels for the target operating life and development of the LCMP. The LCMP documents the strategies and actions planned to facilitate demonstration of FFS of the Fuel Channels throughout the planned operating period. OPG is currently updating the LCMP to comply with applicable requirements of REGDOC-2.6.3 for operation to 2024. FFS is demonstrated and re-assessed on an on-going basis through planned inspections and maintenance, and assessment of inspection results in accordance with the requirements of the CSA N285.4 and N285.8 Standards, and the IAMP and Major

SECTION 3 - GI-1 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

Components Program, using well established programmatic controls.

FFS assessments are based on the condition of the components throughout the life of the plant, usually as determined from the periodic inspections. The inspection results are assessed according to industry standard guideline documents that set out the permissible assessment methodologies and the mandatory requirements. The results are submitted to the regulator in accordance with the CSA N285.4 and N285.8 Standards' requirements, which indicate when regulatory acceptance is required. The inspection techniques and assessment methodologies continue to improve through the Research and Development (R&D) program supported by OPG.

The condition of Pickering Fuel Channels has been projected by OPG to be acceptable for the EFPH values identified in the Assurance of Fuel Channel Fitness for Service submission [P-CORR-00531-04953, *Pickering NGS- Assurance of Fuel Channel Fitness-for-Service for the Assumed Target Life of the Pickering Units*, April 4, 2017] using current assessment methods, models and acceptance criteria. This envelops operation to the end of 2024 for Pickering Units 1,4 and 5-8. OPG acknowledges that there will be continued discussions with CNSC staff regarding methodologies and inputs to the Fuel Channel FFS assessments and compliance with CSA N285.8 Standard that may result in a need to update the FFS assessments. Demonstration of Fuel Channel FFS will be ongoing throughout the planned operating period, following the programmatic controls in place.

LCMPs are prepared based on planned End-of-Operations dates (calendar dates), which are then converted to EFPH values, factoring in outage dates, and anticipated forced loss rates, etc. Each unit is unique in its End-of-Operation EFPH. The LCMPs address legal (regulatory/PIP) requirements, FFS and asset preservation activities. LCMPs are updated on an annual basis to include actions based on results of recent inspections, industry operating experience, R&D findings, and to address activities required due to changes in End-of-Operations dates. Work requirements are established and incorporated into outage and online plans. All LCMP updates are submitted to the CNSC for review, and a completion ratio report is provided to the CNSC annually per the Licence Conditions Handbook.

The current Fuel Channels LCMP [N-PLAN-01060-10002-R017, *Fuel Channels Life Cycle Management Plan*, October 2016] was submitted to the CNSC [N-CORR-00531-18390, OPG Correspondence, *CNSC Staff's Prior Notification of Document Changes: Life Cycle Management Plans*, December 21, 2016]. This LCMP covers Units 5-8 operation to 2024, and Units 1,4 operation to 2022.

The Fuel Channel Life Confirmation Project has completed most of the R&D work required to provide the information needed to support the demonstration of Fuel Channel Fitness for Service to 2024. R&D efforts to support validation of the fracture toughness model will continue as described in the annual update [N-CORR-00531-18461, *Update #5: Annual Update on Approach to Fitness-for-Service Assessment for Pressure Tubes - Action Item 2014-OPG-4782*, February 13, 2017].

Periodic Inspection Plans, in compliance with CSA N285.4, are complete for operation of Pickering 1,4 and, 5-8 to at least 2022, and will be reviewed and revised as required to cover the extended operating period. Application of the CSA N285.4 Standard, which is included in the PROL, provides a process to demonstrate FFS of the inspected Fuel Channels and to seek CNSC acceptance (via the disposition process) for continued operation if the inspected component conditions do not satisfy the CSA N285.4 acceptance criteria.

The CSA N285.8 compliance plan has been accepted by the CNSC [N-CORR-00531-18357, CNSC Correspondence, e-Doc 5126091, *Darlington and Pickering NGS: Revised CSA N285.8 Compliance*

SECTION 3 - GI-1 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

Plan Submission - New Action Item 2016-OPG-8975, December 5, 2016], on condition of inclusion of CNSC comments provided in the correspondence.

OPG will not operate a unit when Fuel Channel FFS has not been demonstrated.

The current Licence limit for Fuel Channel operation of 247,000 EFPH is expected to be removed or revised when the Pickering Power Reactor Operating Licence is renewed. OPG will provide more detail in the Fuel Channel Life Cycle Management Plan. The LCMP will continue to be submitted annually to CNSC staff as prescribed by the Licence Conditions Handbook. The LCMP will include a summary of relevant R&D and assessment methodology updates that may impact Fuel Channel FFS for Pickering NGS operation to 2024. The LCMP will include a table of all current Fuel Channel FFS assessments that have been provided to CNSC, including a summary of assessment results vs. acceptance criteria and the evaluation period addressed. On the basis of the reported results and the continued plans for inspections and implementation of identified/planned mitigations, OPG will state its level of confidence in demonstrating the continued fitness for service for Fuel Channels to the assumed service life targets or, if necessary, to an adjusted service life based on the results. In this way, with the revised LCMP structure in place, continued reporting will provide ongoing fitness for service assessment projections through the extended operating period, using latest Fuel Channel condition information, projection tools, and limits.

SECTION 4 - GI-1 PRIORITY DETERMINATION

Safety Significance of Global Issue	**Deterministic Considerations**			**Probabilistic Considerations**								**Overall Safety Significance Level**
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	1	N/A	**1**	4	1	4	1	N/A	N/A	N/A	**1**	**1**

Rationale:

Addressing this Global Issue assures the ongoing Fitness for Service of Fuel Channels for the operational life of the station. The Fuel Channels are part of the Heat Transport System pressure boundary and, as such, assurance of fitness for service is essential for the safe operation of the plant. As discussed in Section 3 of this Global Issue, OPG has an ongoing effective Major Components Program in place to ensure Fuel Channel fitness for service. In addition, OPG will operate a unit only with Fuel Channels that are fit for service.

SECTION 4 - GI-1 PRIORITY DETERMINATION

Nevertheless, this Global Issue has Safety Significance Level 1 for deterministic considerations with respect to Defence in Depth (E1), since addressing it will ensure the effectiveness of the pressure boundary barrier, which is consistent with the definition of Safety Significance Level 1 in Table E1 in the PSR2 Basis Document. Safety Significance Levels (E2) is considered not applicable, since this Global Issue potentially impacts a physical nuclear safety barrier, whereas E2 primarily relates to issues that impact other objectives or are indirectly related to nuclear safety. Hence, the overall Safety Significance Level of 1 for deterministic considerations is dictated by the E1 categorization.

With respect to probabilistic considerations, the Fuel Channels represent a safety barrier, the effectiveness of which can potentially be impacted by a postulated initiating event with a frequency of approximately 10^{-2}/y. Consistent with Table F2 in the PSR2 Basis Document, the Safety Significance Level is 1 for Defence-in-Depth (F2). Similarly, the Safety Significance Level with respect to Plant Operability (F4) is 1, since addressing this Global Issue will prevent an extended period of plant shutdown due to fitness for service issues.

A Safety Significance Level of 4 is assigned for Reactor Safety – Core Damage Frequency (F1). Potential failure of Fuel Channels is accounted for in the Probabilistic Safety Assessment, and resolution of this Global Issue will ensure that the assumptions in the Probabilistic Safety Assessment regarding Fuel Channel failure frequency remain valid. Therefore, the change in the Core Damage Frequency will be less than 10^{-7}/y, which corresponds to the fourth row of Table F1 in the PSR2 Basis Document, for which the Safety Significance Level is 4.

With respect to Public Radiation Safety (F3), the radiological consequences of a postulated Fuel Channel failure are already accounted for in the safety analysis and shown to be within regulatory limits. Therefore, this Global Issue will result in no adverse change in Public Radiation Safety (F3), which is the determining factor for the applicability of this consideration, and thus the Safety Significance Level is 4.

This Global Issue has no direct impact on the other probabilistic considerations, i.e., Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these probabilistic considerations are not applicable.

In summary, both deterministic and probabilistic considerations dictate that this Global Issue has Safety Significance Level 1. As noted, OPG's existing programs address this issue on an ongoing basis to ensure Fuel Channel fitness for service for the operational life of the station.

SECTION 5 - GI-1 RESOLUTION PLAN

GI-1-RS1	Complete CSA N285.8 Compliance Plan activities, including responding to comments specified in [N-CORR-00531-18357, CNSC Correspondence, e-Doc 5126091, *Darlington and Pickering NGS: Revised CSA N285.8 Compliance Plan Submission - New Action Item 2016-OPG-8975*, December 5, 2016]. (SF4-16) (COP-1) (COP-AG3) This Resolution Statement also includes/addresses GI-22.
GI-1-RS2	Review and revise if/as required the CSA N285.4 compliant Periodic Inspection Plans for Fuel Channels for Pickering NGS to cover the extended operating period. (SF2-1) (SF2-3)

SECTION 5 - GI-1 RESOLUTION PLAN	
GI-1-RS3	Update the Fuel Channels LCMP [N-PLAN-01060-10002-R017, OPG Plan, *Fuel Channels Life-Cycle Management Plan*, October 2016] for Pickering Units 1,4 for the extended operating period. (SF2-3) This Resolution Statement also includes/addresses GI-22 and GI-33.
GI-1-RS4	Update the structure of the Fuel Channels LCMP [N-PLAN-01060-10002-R017, OPG Plan, *Fuel Channels Life-Cycle Management Plan*, October 2016] to demonstrate compliance with REGDOC-2.6.3 for operations to 2024, and to include a summary of relevant R&D and assessment methodology updates that may impact Fuel Channel FFS for Pickering NGS operation. The LCMP structure will include a table of all current Fuel Channel FFS assessments that have been provided to CNSC, as well as a summary of assessment results vs. acceptance criteria and the evaluation period addressed. The FFS for Fuel Channels includes demonstration of sufficient margin of the structural integrity of the pressure tubes, calandria tubes and garter springs (annulus spacers) during the continued operational life of the plant. Based on the reported results, R&D activities, and the continued plans for inspections as well as implementation of identified/planned mitigations, the LCMP will establish a basis to demonstrate the continued fitness for service of Fuel Channels. (SF2-1) (SF2-2) (COP-1) (COP-AG2) (COP-AG4) (SF2-AG1 Items (a) and (b)) OPG is actively progressing this work in support of extended operations at Pickering NGS.

B.2. GI-2 Fitness for Service for Feeders

SECTION 1 - GI-2 GLOBAL ISSUE SUMMARY					
The goal of GI-2, Fitness for Service for Feeders, is to ensure that Feeders remain fit for service for the extended operating period. This Global Issue comprises one proposed Resolution Statement addressing three Gaps: two SF2 review task Gaps and one COP Review Gap. GI-2 is Safety Significance Level 1 based on deterministic and probabilistic defence-in-depth considerations as well as plant operability considerations. OPG's Integrated Aging Management Program, N-PROG-MP-0008-R006, is supported by the Major Components Program, N-PROG-MA-0025-R002, and provides the systematic governance process to ensure ongoing Feeder fitness for service. Life Cycle Management Plans developed under this governance are in place. The Life Cycle Management Plans currently cover the period to 2022 for Pickering 1,4 and 2024 for Pickering 5-8. The proposed Resolution Plan primarily comprises activities to update the Life Cycle Management Plan, to document the basis for ensuring that Feeders will remain fit for service for the extended operating period. The update is to include a planned Feeder replacement plan/schedule to address the extended operating period. Completion of the proposed Resolution Plan will support and strengthen Level 1 defence-in-depth for the extended operating period.					
Safety Significance Level:	1	**Category:**	Programmatic, Engineering, Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-2 ASSOCIATED GAPS	
SF2-4	Fitness for Service for Feeders has not been demonstrated for station operation to 2028[33]. ***Review Task #1 Actual Condition of SSCs*** **Associated Resolutions:** GI-2-RS1
SF2-5	The Feeders LCMP has not been formally updated to address extended station operation to 2028[33]. ***Review Task #1 Actual Condition of SSCs*** **Associated Resolutions:** GI-2-RS1
COP-8	The Pickering Feeder replacement schedule/plan (including Feeder IDs and the supporting rationale, including life limits, for specific Feeder replacement) has not been updated to support extended operation for Pickering Units 1,4 and 5-8. ***Pickering PSR2 Gap COP-8*** **Associated Resolutions:** GI-2-RS1

SECTION 3 - GI-2 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains three Gaps (two SF2 Gaps and one COP Review Gap) that are related to FFS and the LCMP for Feeders.

In a process similar to that described in GI-1, OPG has well established programmatic controls to demonstrate FFS for Feeders. FFS is demonstrated through application of the OPG Integrated Aging Management Program (IAMP) [N-PROG-MP-0008-R006, *Integrated Aging Management*, April 29, 2016]. IAMP is based on understanding of the component and system design, materials, degradation mechanisms and operating environment. IAMP provides a Plan – Do – Check – Act cycle of activities to support continued fitness for service throughout the planned service life of the component. Application of the IAMP process, via the OPG Major Components Program [N-PROG-MA-0025-R002, *Major Components*, March 25, 2015] establishes a basis for demonstration of FFS for the Feeders for the target operating life and development of the LCMP. The LCMP documents the strategies and actions planned to facilitate demonstration of FFS of the Feeders throughout the planned operating period. FFS is demonstrated and re-assessed on an on-going basis through planned inspections and maintenance, and assessment of inspection results in accordance with the requirements of the CSA N285.4 Standard, and the IAMP and Major Components Program, using well established programmatic controls.

LCMPs are prepared based on planned End-of-Operations dates (calendar dates), which are then converted to EFPH values, factoring in outage dates, and anticipated forced loss rates etc. Each unit is unique in its End-of-Operation EFPH or its component end-of-life date. The current Feeders LCMP [N-PLAN-01060-10001-R018, OPG Plan, *Feeders Life Cycle Management Plan*, October 2016] was submitted to the CNSC [N-CORR-00531-18390, OPG Correspondence, *CNSC Staff's Prior Notification of Document Changes: Life Cycle Management Plans*, December 21, 2016]. This LCMP covers Units 5-8 operation to 2024, and Units 1,4 operation to 2022.

Periodic Inspection Plans, in compliance with CSA N285.4, are complete for operation of Pickering 1,4 and 5-8 to at least 2022, and will be reviewed and revised as required to cover the extended operating period. Application of the CSA N285.4 Standard, which is included in the PROL, provides a process to demonstrate FFS of the inspected Feeders and to seek CNSC acceptance (via the disposition process) for continued operation if the inspected component conditions do not satisfy the CSA N285.4 acceptance criteria.

All LCMP updates are submitted to the CNSC for information and a completion status report is provided to the CNSC annually.

SECTION 4 - GI-2 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	1	N/A	**1**	4	1	4	1	N/A	N/A	N/A	**1**	**1**

Rationale:

Addressing this Global Issue assures the ongoing fitness for service of Feeders for the operational life of the station. The Feeders are part of the Heat Transport System pressure boundary and, as such, assurance of fitness for service is important for the safe operation of the plant. As discussed in Section 3 of this Global Issue, OPG has an ongoing effective Major Components Program in place to ensure Feeders fitness for service. In addition, OPG will operate a unit only with Feeders that are fit for service.

Nevertheless, this Global Issue has Safety Significance Level 1 for deterministic considerations with respect to Defence in Depth (E1), since addressing it will ensure the effectiveness of the pressure boundary barrier, which is consistent with the definition of Safety Significance Level 1 in Table E1 in the PSR2 Basis document. Safety Significance Levels (E2) is considered not applicable, since this Global Issue potentially impacts a physical nuclear safety barrier, whereas E2 primarily relates to issues that impact other objectives or are indirectly related to nuclear safety. Hence, the overall Safety Significance Level of 1 for deterministic considerations is dictated by the E1 categorization.

With respect to probabilistic considerations, the Feeders represent a safety barrier, the effectiveness of which can potentially be impacted by a postulated initiating event of frequency of approximately 10^{-2}/y. Consistent with Table F2 in the PSR2 Basis Document, the Safety Significance Level is 1 for Defence in Depth (F2). Similarly, the Safety Significance Level with respect to Plant Operability (F4) is 1, since addressing this Global Issue will prevent an extended period of plant shutdown due to fitness for service issues.

A Safety Significance Level of 4 is assigned for Reactor Safety – Core Damage Frequency (F1). Potential failure of feeders is accounted for in the Probabilistic Safety Assessment, and resolution of this Global Issue will ensure that the assumptions in the Probabilistic Safety Assessment regarding Feeder failure frequency remain valid. Therefore, the change in the Core Damage Frequency will be less than 10^{-7}/y, which corresponds to the fourth row of Table F1 in the PSR2 Basis Document, for which the Safety Significance Level is 4.

With respect to Public Radiation Safety (F3), the radiological consequences of a postulated Feeder failure are already accounted for in the safety analysis and are within regulatory limits. Therefore, this

SECTION 4 - GI-2 PRIORITY DETERMINATION
Global Issue will result in no adverse change in Public Radiation Safety (F3), which is the determining factor for the applicability of this consideration, and thus the Safety Significance Level is 4. This Global Issue has no direct impact on the other probabilistic factors, i.e., Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these probabilistic considerations are not applicable. In summary, both deterministic and probabilistic considerations dictate that this Global Issue has Safety Significance Level 1. As noted, OPG's existing programs address this issue on an ongoing basis to ensure fitness-for-service of the Feeders for the operational life of the station.

SECTION 5 - GI-2 RESOLUTION PLAN	
GI-2-RS1	Update the Feeders LCMP [N-PLAN-01060-10001-R018, OPG Plan, *Feeders Life Cycle Management Plan*, October 2016], based on updated Fitness for Service assessment for Pickering Units 1,4 for the extended operating period. The LCMP update is to support continued demonstration that predicted Feeder condition, with identified and planned mitigations, is acceptable for the intended operation, including any potential impact of Fuel Channel elongation on Feeder integrity. The Feeders LCMP update is to include a planned Feeder replacement plan/schedule to address the extended operating period. (SF2-4) (SF2-5) (COP-8) This Resolution Statement also includes/addresses GI-22 and GI-33. OPG is actively progressing this work in support of extended operation at Pickering NGS.

B.3. GI-3 Fitness for Service for Steam Generators

SECTION 1 - GI-3 GLOBAL ISSUE SUMMARY					
The goal of GI-3, Fitness for Service for Steam Generators, is to ensure that Steam Generators remain fit for service for the extended operating period. This Global Issue comprises one proposed Resolution Statement addressing three Gaps: two SF2 review task Gaps and one COP Review Gap. GI-3 is Safety Significance Level 1 based on deterministic and probabilistic defence-in-depth considerations as well as plant operability considerations. OPG's Integrated Aging Management Program, N-PROG-MP-0008-R006, is supported by the Major Components Program, N-PROG-MA-0025-R002, and provides the systematic governance process to ensure ongoing Steam Generator fitness for service. Life Cycle Management Plans developed under this governance are in place. The Life Cycle Management Plans currently cover the period to 2022 for Pickering 1,4 and 2024 for Pickering 5-8. The proposed Resolution Plan primarily comprises activities to update the Life Cycle Management Plan, to document the basis for ensuring that Steam Generators will remain fit for service for the extended operating period. Completion of the proposed Resolution Plan will support and strengthen Level 1 defence-in-depth for the extended operating period.					
Safety Significance Level:	1	**Category:**	Programmatic, Engineering, Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-3 ASSOCIATED GAPS	
SF2-6	Fitness for Service for Steam Generators has not been demonstrated for station operation to 2028[33]. ***Review Task #1 Actual Condition of SSCs*** **Associated Resolutions:** GI-3-RS1
SF2-7	The Steam Generators LCMP has not been formally updated to address extended station operation to 2028[33]. ***Review Task #1 Actual Condition of SSCs*** **Associated Resolutions:** GI-3-RS1
COP-9	Demonstration has not been completed for extended operation[33] to confirm that sufficient margin remains in the operating life of the Pickering Steam Generators (residual life based on the TLAA), Steam Generator tubes and tube supports, shell, attachment welds and other internals considering the original design requirements and the OPEX on in-service degradation with respect to: • thermal cyclic fatigue;

SECTION 2 - GI-3 ASSOCIATED GAPS

- mechanical fatigue;
- corrosion allowances; and
- other types of degradation mechanisms.

Pickering PSR2 Gap COP-9

Associated Resolutions: GI-3-RS1

SECTION 3 - GI-3 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains three Gaps (two SF2 Gaps and one COP Review Gap) that are related to FFS and the LCMP for Steam Generators.

In a process similar to that described in GI-1, OPG has well established programmatic controls to demonstrate FFS for Steam Generators. FFS is demonstrated through application of the OPG Integrated Aging Management Program (IAMP) [N-PROG-MP-0008-R006, *Integrated Aging Management*, April 29, 2016]. IAMP is based on understanding of the component and system design, materials, degradation mechanisms and operating environment. IAMP provides a Plan – Do – Check – Act cycle of activities to support continued fitness for service throughout the planned service life of the component. Application of the IAMP process, via the OPG Major Components Program [N-PROG-MA-0025-R002, *Major Components*, March 25, 2015] establishes a basis for demonstration of FFS for the Steam Generators for the target operating life and development of the LCMP. The LCMP documents the strategies and actions planned to facilitate demonstration of FFS of the Steam Generators throughout the planned operating period. FFS is demonstrated and re-assessed on an on-going basis through planned inspections and maintenance, and assessment of inspection results in accordance with the requirements of the CSA N285.4 Standard, and the IAMP and Major Components Program, using well established programmatic controls.

LCMPs are prepared based on planned End-of-Operations dates (calendar dates), which are then converted to EFPH values, factoring in outage dates, and anticipated forced loss rates etc. Each unit is unique in its End-of-Operation EFPH or its component end-of-life date. The current Steam Generators LCMP [N-PLAN-33110-10009-R007, OPG Plan, *Steam Generators Life Cycle Management Plan*, October 2016] was submitted to the CNSC [N-CORR-00531-18390, OPG Correspondence, *CNSC Staff's Prior Notification of Document Changes: Life Cycle Management Plans*, December 21, 2016]. This LCMP covers Units 5-8 operation to 2024, and Units 1,4 operation to 2022.

Periodic Inspection Plans, in compliance with CSA N285.4, are complete for operation of Pickering 1,4 and, 5-8 to at least 2022, and will be reviewed and revised as required to cover the extended operating period. Application of the CSA N285.4 Standard, which is included in the PROL, provides a process to demonstrate FFS of the inspected Steam Generators and to seek CNSC acceptance (via the disposition process) for continued operation if the inspected component conditions do not satisfy the CSA N285.4 acceptance criteria.

All LCMP updates are submitted to the CNSC for information and a completion status report is provided to the CNSC annually.

SECTION 4 - GI-3 PRIORITY DETERMINATION

Safety Significance of Global Issue	**Deterministic Considerations**			**Probabilistic Considerations**								**Overall Safety Significance Level**
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	1	N/A	**1**	4	1	4	1	N/A	N/A	N/A	**1**	**1**

Rationale:

Addressing this Global Issue assures the ongoing fitness for service of Steam Generators for the operational life of the station. The Steam Generators are part of the Heat Transport System pressure boundary and, as such, assurance of fitness for service is important for the safe operation of the plant. As discussed in Section 3 of this Global Issue, OPG has an ongoing effective Major Components Program in place to ensure Steam Generator fitness for service.

Nevertheless, this Global Issue has Safety Significance Level 1 for deterministic considerations with respect to Defence in Depth (E1) since addressing it will ensure the effectiveness of the pressure boundary barrier, which is consistent with the definition of Safety Significance Level 1 in Table E1 in the PSR2 Basis document. Safety Significance Levels (E2) is considered not applicable since this Global Issue potentially impacts a physical nuclear safety barrier, whereas E2 primarily relates to issues that impact other objectives or that are indirectly related to nuclear safety. Hence, the overall Safety Significance Level of 1 for deterministic considerations is dictated by the E1 categorization.

With respect to probabilistic considerations, the Steam Generator tubes represent a safety barrier, the effectiveness of which can be impacted by a postulated initiating event of frequency of approximately 10^{-2}/y. Consistent with Table F2 in the PSR2 Basis Document, the Safety Significance Level is 1 for Defence in Depth (F2). The Safety Significance Level with respect to Plant Operability (F4) is also 1, since addressing this Global Issue prevents an extended period of plant shutdown due to fitness for service issues.

Safety Significance Level 4 is assigned to Core Damage Frequency (F1) since this Global Issue has an insignificant impact on this consideration. With respect to Public Radiation Safety (F3), the radiological consequences of a Steam Generator tube failure are already accounted for in the safety analysis and are within regulatory limits. Therefore, this Global Issue will result in no adverse change in Public Radiation Safety (F3), which is the determining factor for the applicability of this consideration, and thus the Safety Significance Level is 4. This Global Issue has no direct impact on the other probabilistic factors: Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these probabilistic considerations are not applicable.

SECTION 4 - GI-3 PRIORITY DETERMINATION
In summary, both deterministic and probabilistic considerations dictate that this Global Issue has Safety Significance Level 1. As noted, OPG's existing programs address this issue on an ongoing basis to ensure Steam Generators fitness for service for the operational life of the station.

SECTION 5 - GI-3 RESOLUTION PLAN	
GI-3-RS1	Update the Steam Generators LCMP [N-PLAN-33110-10009-R007, OPG Plan, *Steam Generators Life Cycle Management Plan*, October 2016], based on updated Fitness for Service assessment for Pickering Units 1,4 for the extended operating period. The LCMP update is to support continued demonstration that predicted Steam Generator condition, with identified and planned mitigations, is acceptable for the intended operation. (SF2-6) (SF2-7) (COP-9) This Resolution Statement also includes/addresses GI-22 and GI-33. OPG is actively progressing this work in support of extended operation at Pickering NGS.

B.4. GI-4 Fitness for Service for Reactor Components and Structures

SECTION 1 - GI-4 GLOBAL ISSUE SUMMARY					
The goal of GI-4, Fitness for Service for Reactor Components and Structures, is to ensure that the Reactor Components and Structures remain fit for service for the extended operating period. The major equipment within this category includes the Calandria Vessel, Calandria Tubes, Guide Tubes, Moderator Inlet Piping and Nozzles, Reactivity Control Units, Calandria Relief Ducts, Lattice Tubes and End Fittings, as well as Exposed Carbon Steel Components in the Calandria Vault. This Global Issue comprises two proposed Resolution Statements addressing nine Gaps: two SF2 review task Gaps, six COP Review Gaps and one SF2 Additional Gap. GI-4 is Safety Significance Level 2 based on deterministic and probabilistic defence-in-depth considerations as well as plant operability considerations. OPG's Integrated Aging Management Program, N-PROG-MP-0008-R006, is supported by the Major Components Program, N-PROG-MA-0025-R002, and provides the systematic governance process to ensure the ongoing fitness for service of Reactor Components and Structures. Life Cycle Management Plans developed under this governance are in place. The Life Cycle Management Plans currently cover the period to 2022 for Pickering 1,4 and 2024 for Pickering 5-8. The proposed Resolution Plan includes activities to update the Life Cycle Management Plan, to document the basis for ensuring that Reactor Components and Structures will remain fit for service for the extended operating period. In addition, the proposed Resolution Plan includes updating measurements and analysis of the gap between Liquid Injection Shutdown System nozzles and Calandria Tubes, and implementing mitigation strategies, if required. Completion of the proposed Resolution Plan will support and strengthen Level 1 defence-in-depth for the extended operating period.					
Safety Significance Level:	2	**Category:**	Programmatic, Engineering, Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-4 ASSOCIATED GAPS	
SF2-8	Fitness for Service for Reactor Components and Structures has not been demonstrated for station operation to 2028[33]. ***Review Task #1 Actual Condition of SSCs*** **Associated Resolutions:** GI-4-RS1, GI-4-RS2
SF2-9	The Reactor Components and Structures LCMP has not been formally updated to address extended station operation to 2028[33]. ***Review Task #1 Actual Condition of SSCs*** **Associated Resolutions:** GI-4-RS1

SECTION 2 - GI-4 ASSOCIATED GAPS	
COP-2	Demonstration of adequate margin to operate the Pickering Units 5-8 SDS2 LISS by performing piping fatigue and aging analysis has not been completed for the extended operation period[33] and for the period until LISS can be demonstrated to no longer be required. ***Pickering PSR2 Gap COP-2*** **Associated Resolutions:** GI-4-RS2
COP-10	Fitness for Service demonstration of the Pickering Units 1,4 and 5-8 Calandrias to address the full period of extended operation[33] has not been completed. ***Pickering PSR2 Gap COP-10*** **Associated Resolutions:** GI-4-RS1
COP-11	The Pickering Calandria Tube life assessment has not been updated for the full period of extended operation[33]. ***Pickering PSR2 Gap COP-11*** **Associated Resolutions:** GI-4-RS1, GI-4-RS2
COP-12	OPG requirements and plans for inspection and monitoring of Reactor Components have not been updated to address the full period of extended operation[33] of Pickering Units 1,4 and 5-8. ***Pickering PSR2 Gap COP-12*** **Associated Resolutions:** GI-4-RS1
COP-13	The Calandria and internal structures Technical Basis Document for Pickering Units 1,4 and 5-8, which includes OPEX, and FFS rationale to support that Calandria and internal components will remain fit has not been updated for the full period of extended operation[33]. ***Pickering PSR2 Gap COP-13*** **Associated Resolutions:** GI-4-RS1
COP-26	A review for the full period of extended operation[33] has not been completed of evidence that Calandria and internal structure guide tube springs for Pickering Units 1,4 and 5-8 will remain fit for service. ***Pickering PSR2 Gap COP-26*** **Associated Resolutions:** GI-4-RS1
SF2-AG1	An SF2 Gap related to updating the Fuel Channels Life Cycle Management Plan as well as the Technical Basis used in the Fuel Channels Life Cycle Management Plan, documentation on mitigating actions such as R&D and extent of condition of each aging degradation mechanism, and the potential for CT/LISS contact prior to 2024 due to fuel channel sag, was identified in [P-CORR-00531-05099, e-Doc 5295534, July 12, 2017].

SECTION 2 - GI-4 ASSOCIATED GAPS

The associated resolution addresses Item (c) of the reference. Items (a) and (b) are addressed by GI-1.

Associated Resolutions: GI-4-RS2

SECTION 3 - GI-4 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains nine Gaps (two SF2 Gaps, six COP Review Gaps and one SF2 Additional Gap) that are related to FFS and the LCMP for Reactor Components and Structures.

In a process similar to that described in GI-1, OPG has well established programmatic controls to demonstrate FFS for Reactor Components and structures. FFS is demonstrated through application of the OPG Integrated Aging Management Program (IAMP) [N-PROG-MP-0008-R006, *Integrated Aging Management*, April 29, 2016]. IAMP is based on understanding of the component and system design, materials, degradation mechanisms and operating environment. IAMP provides a Plan – Do – Check – Act cycle of activities to support continued fitness for service throughout the planned service life of the component. Application of the IAMP process, via the OPG Major Components Program [N-PROG-MA-0025-R002, *Major Components*, March 25, 2015] establishes a basis for demonstration of FFS for the Reactor Components and structures for the target operating life and development of the LCMP. The LCMP documents the strategies and actions planned to facilitate demonstration of FFS of the Reactor Components and structures throughout the planned operating period. FFS is demonstrated and re-assessed on an on-going basis through planned inspections and maintenance, and assessment of inspection results in accordance with the IAMP and Major Components Program, using well established programmatic controls.

LCMPs are prepared based on planned End-of-Operations dates (calendar dates), which are then converted to EFPH values, factoring in outage dates, and anticipated forced loss rates etc. Each unit is unique in its End-of-Operation EFPH or its component end-of-life date. The current Reactor Components and Structures LCMP [N-PLAN-01060-10003-R014, OPG Plan, *Reactor Components and Structures Life Cycle Management Plan*, October 2016] was submitted to the CNSC [N-CORR-00531-18390, OPG Correspondence, *CNSC Staff's Prior Notification of Document Changes: Life Cycle Management Plans*, December 21, 2016]. This LCMP covers Units 5-8 operation to 2024, and Units 1,4 operation to 2022.

Based on work performed under CANDU Owners Group (COG) Joint Project JP 4271 [COG-JP-4271-004, COG Report, *Calandria Fitness For Life Extension Guidelines: Phase 3*, May 2013], no component is identified as "must be replaced after 30 years operation" and there are no active degradation mechanisms or adverse conditions that would require imminent actions in the Pickering Units for operation extension for an additional 210,000 EFPH beyond 30 years of operation.

Baseline Calandria Tube - Liquid Injection Shutdown System (CT-LISS) nozzle gap assessments [N-PLAN-01060-10003-R014, OPG Plan, *Reactor Components and Structures Life Cycle Management Plan*, October 2016] show no contact is predicted to:

Unit 5: 268,000 EFPH

Unit 6: 256,000 EFPH

SECTION 3 - GI-4 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

Unit 7: >300,000 EFPH

Unit 8**:** 283,000 EFPH

These assessments use the baseline measurements of CT-LISS gaps in the units, except for Unit 7 where an additional measurement was done to obtain gap closure rate information. Additional measurements of CT-LISS nozzle gaps, per the Reactor Components and Structures LCMP [N-PLAN-01060-10003-R014, OPG Plan, *Reactor Components and Structures Life Cycle Management Plan*, October 2016], will be used to refine the gap closure rates. In the event that CT-LISS nozzle contact is predicted prior to the End-of-Operations, mitigation strategies will be developed and implemented.

All LCMP updates are submitted to the CNSC for information.

SECTION 4 - GI-4 PRIORITY DETERMINATION

Safety Significance of Global Issue	**Deterministic Considerations**			**Probabilistic Considerations**								**Overall Safety Significance Level**
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	2	N/A	**2**	4	2	4	2	N/A	N/A	N/A	**2**	**2**

<u>Rationale:</u>

Addressing this Global Issue assures the ongoing fitness for service of Reactor Components and structures for the operational life of the station. Reactor functions can be impacted by the aged conditions of these components and structures and, as such, assurance of fitness for service is important for the safe operation of the plant. As discussed in Section 3 of this Global Issue, OPG has an ongoing effective Major Components Program in place to ensure fitness for service of the Reactor Components and structures.

Nevertheless, this Global Issue has Safety Significance Level 2 for deterministic considerations with respect to Defence in Depth (E1) since ensuring fitness for service will prevent a reduction in margin of safety to the public or station personnel (Table E1 of the PSR2 Basis Document). Safety Significance Levels (E2) is considered not applicable since this Global Issue can have a direct impact on nuclear safety, whereas E2 primarily relates to issues without a direct impact on nuclear safety. Hence, the overall Safety Significance Level of 2 for deterministic considerations is dictated by the E1 categorization.

SECTION 4 - GI-4 PRIORITY DETERMINATION

With respect to probabilistic considerations, this Global Issue is assigned Safety Significance Level 2 for Defence in Depth (F2). This is because addressing the issues related to Calandria Tube/Liquid Injection Shutdown System nozzle gap or active aging mechanisms will prevent a potential adverse impact on the reactor Shutdown System, preventing a potential loss in the reliability of this system in mitigating events with frequency of approximately 10^{-2}/y. Similarly, the Safety Significance Level with respect to Plant Operability (F4) is also 2, since an extended period of plant shutdown as a result of fitness for service issues is expected to have low probability (less than 0.1). Safety Significance Level 4 is assigned to Core Damage Frequency (F1) and Public Radiation Safety (F3) since this Global Issue has an insignificant impact on these considerations. This Global Issue has no direct impact on the other probabilistic factors, i.e., Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these probabilistic considerations are not applicable.

In summary, both deterministic and probabilistic considerations dictate that this Global Issue has Safety Significance Level 2. As noted, OPG's existing programs address this issue on an ongoing basis to ensure Reactor Components and structures fitness for service for the operational life of the station.

SECTION 5 - GI-4 RESOLUTION PLAN

GI-4-RS1	Update the Reactor Components and Structures LCMP [N-PLAN-01060-10003-R014, OPG Plan, *Reactor Components and Structures Life Cycle Management Plan*, October 2016], based on updated Fitness for Service assessment and an updated Technical Basis Document [N-PLAN-01060-10008 R00, *Reactor Components & Structures Life Cycle Management Plan: Technical Basis Document*, 2010] for Pickering Units 1,4 for the extended operating period. The LCMP update is to support continued demonstration that predicted Reactor Components and Structures condition, with identified and planned mitigations, is acceptable for the intended operation. (SF2-8) (SF2-9) (COP-10) (COP-11) (COP-12) (COP-13) (COP-26) This Resolution Statement also includes/addresses GI-22 and GI-33.
GI-4-RS2	Perform measurements, as required, of CT-LISS nozzle gaps on Units 5-8 to refine the gap closure rates. Using this new measurement data, update analyses as required, to demonstrate Fitness for Service. Implement mitigation strategies if CT-LISS nozzle contact is predicted within the extended operating period. (SF2-8) (COP-2) (COP-11) (SF2-AG1 Item (c)). This Resolution Statement also includes/addresses GI-22. OPG is actively progressing this work in support of extended operation at Pickering NGS.

B.5. GI-5 Completeness of Class 1 Piping / Components Service Limits Assessment (Excluding Major Components)

SECTION 1 - GI-5 GLOBAL ISSUE SUMMARY					
The goal of GI-5, Completeness of Class 1 Piping/Components Service Limits Assessment (excluding major components), is to confirm the adequacy of the service limits assessments for Nuclear Class 1 piping and components for the extended operating period. This Global Issue comprises one proposed Resolution Statement and one item requiring No Further Action, addressing three Gaps: one SF2 review task Gap and two COP Review Gaps. GI-5 is Safety Significance Level 2 based on deterministic and probabilistic defence-in-depth considerations as well as plant operability considerations. The service limits assessments for Nuclear Class 1 components (including piping) are complete to 2028 [P-CORR-33000-00001], but the updated piping assessments have not incorporated environmental factors. Therefore, the proposed Resolution Plan comprises activities to confirm the adequacy of the service limits assessments for Nuclear Class 1 Piping (excluding major components) after accounting for the impact of environmental factors such as irradiation, temperature, humidity, etc. Completion of the proposed Resolution Plan will support and strengthen Level 1 defence-in-depth for the extended operating period.					
Safety Significance Level:	2	**Category:**	Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-5 ASSOCIATED GAPS	
COP-3	Demonstration of adequate margin to operate the Pickering Primary Heat Transport piping has not been completed for the extended operation period and for the period until Primary Heat Transport piping integrity has been demonstrated to no longer be required. ***Pickering PSR2 Gap COP-3*** **Associated Resolutions:** GI-5-NFA1
COP-22	The final report of the Service Limits Assessment for Class 1 components has not been updated taking the full period of extended operation into account for Pickering Units 1,4 and 5-8. ***Pickering PSR2 Gap COP-22*** **Associated Resolutions:** GI-5-NFA1
SF2-10	Environmental Factors have not been incorporated into the Service Limits Assessment for Class 1 piping. ***Review Task #1 Actual Condition of SSCs***

SECTION 2 - GI-5 ASSOCIATED GAPS

Associated Resolutions: GI-5-RS1

SECTION 3 - GI-5 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains three Gaps (one SF2 Gap and two COP Review Gaps) that are related to the service limits of Class 1 Piping and Components (excluding Major Components).

SECTION 4 - GI-5 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	2	N/A	**2**	3	2	4	2	N/A	N/A	N/A	**2**	**2**

Rationale:

Addressing this Global Issue is part of assuring the fitness for service of Class 1 Piping/Components (excluding Major Components) for the operational life of the station. Class 1 Piping/Components Service Limits of the Major Components are addressed in the Major Components LCMPs (GI-1, GI-2, and GI-3). Resolution of this Global Issue will confirm that the original design of Class 1 Piping/Components (excluding Major Components) covers the extended operating period.

This Global Issue has Safety Significance Level 2 for deterministic considerations with respect to Defence in Depth (E1) since addressing it will contribute to preventing a margin reduction in fitness-for-service of the Heat Transport System barrier throughout the extended operation period (row 2 of Table E1 in the PSR2 Basis Document). Safety Significance Levels (E2) is considered not applicable, since this Global Issue potentially can have a direct impact on nuclear safety, whereas E2 primarily relates to issues without a direct impact on nuclear safety. Moreover, assignment of Safety Significance Level 2 for Defence in Depth (E1) subsumes any considerations for Safety Significance Levels (E2). Hence, the overall Safety Significance Level of 2 for deterministic considerations is dictated by the E1 categorization.

With respect to probabilistic considerations, for Defence in Depth (F2), this Global Issue has a Safety

SECTION 4 - GI-5 PRIORITY DETERMINATION
Significance Level 2 since confirming that service level C conditions for the Heat Transport System are met throughout the operational life is a means to confirm that safety margins are preserved. Therefore, row 3 of Table F2 in the PSR2 Basis Document is applicable, with 2 being the highest Safety Significance Level in this row. Similarly, the Safety Significance Level with respect to Plant Operability (F4) is 2, because the probability of an extended period of plant shutdown due to this Global Issue is less than 0.1. Safety Significance Level 3 is assigned to Core Damage Frequency (F1) since the failure probability of Class I piping is very low. Safety Significance Level 4 is assigned to Public Radiation Safety (F3) since this Global Issue has an insignificant impact on these considerations. This Global Issue has no direct impact on the other probabilistic considerations, i.e., Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these probabilistic considerations are not applicable. In summary, both deterministic and probabilistic considerations dictate that this Global Issue has Safety Significance Level 2. As noted, OPG's existing programs address this issue on an ongoing basis to ensure fitness for service of Class 1 Piping/Components (excluding Major Components) for the operational life of the station.

SECTION 5 - GI-5 RESOLUTION PLAN	
GI-5-RS1	Confirm the adequacy of the service limits assessments for Nuclear Class 1 Piping after accounting for impact of environmental factors (for example: irradiation, temperature, humidity). Note – This Resolution Statement does not address Major Components. (SF2-10) This Resolution Statement also includes/addresses GI-33.
GI-5-NFA1	The service limits assessments for Nuclear Class 1 components (including piping) are complete to 2028 [P-CORR-33000-00001, *Pickering NGS Service Limits Assessment of Nuclear Class 1 Components for Potential Life Extension*, June 2016]. No further action is required. Note – This resolution does not address Major Components. (COP-3) (COP-22)

B.6. GI-6 Impact of the Revised Criticality Coding on the Cable Surveillance Program

SECTION 1 - GI-6 GLOBAL ISSUE SUMMARY					
The goal of GI-6, Impact of the Revised Criticality Coding on the Cable Surveillance Program, is to ensure that the on-going implementation of the Cable Surveillance Program takes into account the revised Criticality Coding for determining Cable Risk Rating for the extended operating period. This Global Issue comprises one proposed Resolution Statement addressing one SF2 review task Gap. GI-6 is Safety Significance Level 3 based on deterministic defence-in-depth considerations. The Cable Surveillance Program [N-PROC-MA-0099 R001] establishes scope for low and medium voltage electrical cables connected to Criticality Code 1 or Criticality Code 2 components. The proposed Resolution Plan comprises activities to reassess the impact of the changes in the Cable Criticality Coding and update the scope of the Cable Surveillance Plan accordingly. Completion of the proposed Resolution Plan will support and strengthen Levels 1, 2, 3 and 4 defence-in-depth for the extended operating period because the relevant cables are part of both process systems and mitigating systems.					
Safety Significance Level:	3	**Category:**	Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-6 ASSOCIATED GAPS	
SF2-13	The Cable Surveillance Program risk assessment and Condition Assessments currently use out of date criticality coding. ***Review Task #1 Actual Condition of SSCs*** **Associated Resolutions:** GI-6-RS1

SECTION 3 - GI-6 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains one SF2 Gap related to the Cable Surveillance Program. The Cable Surveillance Program [N-PROC-MA-0099 R001, OPG Nuclear Procedure, *Cable Surveillance*, August 19, 2014] establishes scope for low and medium voltage electrical cables connected to Criticality Code 1 (CC1) or Criticality Code 2 (CC2) components. Recently, changes in Criticality Code occurred as a result of the Criticality Code review project performed by OPG. The on-going implementation of the Cable Surveillance program needs to take into account the revised Criticality Coding for determining Cable Risk Rating for CC1 or CC2 components.

SECTION 4 - GI-6 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	**Overall Safety Significance Level**
	3	N/A	**3**	4	N/A	N/A	N/A	N/A	N/A	N/A	**4**	**3**

Rationale:

This Global Issue is related to the impact of the revised Criticality Coding on the Cable Surveillance Program. The ongoing and future implementation of the Cable Surveillance Program will take into account the updated equipment Criticality Coding when screening for potentially higher risk cables (Criticality Code 1 (CC1) or Criticality Code 2 (CC2)).

Regarding deterministic considerations, this Global Issue is assigned Safety Significance Level 3 for Defence in Depth (E1) since a safety function could be impacted by the issue (row 3 of Table E1 in the PSR2 Basis Document). Safety Significance Levels (E2) is assessed as not applicable since E2 primarily relates to issues without a direct nuclear safety impact. Therefore, Safety Significance Level 3 is selected for deterministic considerations.

Safety Significance Level 4 is assigned to Core Damage Frequency (F1) since the impact of this issue on core damage frequency is expected to be less than 10^{-7}/y. This Global Issue has no or insignificant impact on Defence in Depth (F2), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these probabilistic considerations are not applicable.

In summary, the overall Safety Significance Level is 3. Work is in progress on addressing this Global Issue.

SECTION 5 - GI-6 RESOLUTION PLAN

GI-6-RS1	Reassess the impact of the changes in the cable Criticality Coding and update the scope of the cable surveillance plan accordingly. (SF2-13)

B.7. GI-7 Pickering Buried Piping Fitness for the Extended Operating Period

SECTION 1 - GI-7 GLOBAL ISSUE SUMMARY					
The goal of GI-7, Pickering Buried Piping Fitness for the Extended Operating Period, is to ensure the continued fitness of Pickering Buried Piping for the extended operating period. This Global Issue comprises two proposed Resolution Statements addressing two Gaps: one SF2 review task Gap and one SF1 Additional Review Finding Gap originating from the Darlington IIP. GI-7 is Safety Significance Level 3 based on deterministic and probabilistic defence-in-depth considerations as well as plant operability considerations. Assessments were completed [NA44/NK30-IR-58150-00001] confirming the adequacy of the buried piping to 2020 for Pickering 1,4 and to 2025 for Pickering 5-8, contingent on continuation of condition monitoring per the Buried Piping Program [N-PLAN-04916-10002-R003]. Action Request AR# 28175307 tracks implementation of the governance revision to apply a graded approach in the event that leakage from buried piping occurs. The proposed Resolution Plan comprises activities to update the Buried Piping Program asset management plan and risk ranking for the extended operating period, and to update governance to reflect a graded approach in the event that any leakage in fuel oil piping occurs. Completion of the proposed Resolution Plan will support and strengthen Levels 1, 3 and 4 defence-in-depth for the extended operating period because buried piping is associated with both process and mitigating systems.					
Safety Significance Level:	3	**Category:**	Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-7 ASSOCIATED GAPS	
SF2-14	The Buried Piping Program risk assessment and Condition Assessments have not been updated for extended operation to 2028[33]. ***Review Task #1 Actual Condition of SSCs*** **Associated Resolutions:** GI-7-RS1
SF1-35	Darlington Gap IIP-OI 063 was identified based on the requirement to replace single wall fuel oil piping with double wall piping if degraded piping is found. AR# 28175307 was initiated which required revision of N-PROC-MA-0088, *Buried Piping Program Requirements* to use a graded approach for the replacement of single walled piping with double walled material in instances of leakage. AR# 28175307 currently has corrective actions in place and is expected to be completed by Q1 2020. This issue is also applicable to Pickering NGS and is therefore a Gap for Pickering PSR2. ***Additional Review Findings*** **Associated Resolutions:** GI-7-RS2

SECTION 3 - GI-7 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains two Gaps (one SF1 Gap and one SF2 Gap) related to the Buried Piping Program.

Assessments were completed [NA44-IR-58150-00001, *Assessment of Cathodic Protect ion on Buried Piping Systems in Pickering A Nuclear Generating Station for Continued Operation until 2020*, June 2013] [NK30-IR-58150-00001, *Assessment of Cathodic Protection on Buried Piping Systems in Pickering B Nuclear Generating Station for Continued Operation until 2025*, December 2010] confirming the adequacy of the buried piping to 2020 for Pickering 1,4 and to 2025 for Pickering 5-8, contingent on continuation of condition monitoring per the Buried Piping Program [N-PLAN-04916-10002-R003, OPG Plan*, Buried Piping Program Asset Management Plan*, January 30, 2017]. An update to the Buried Piping Program is required for the extended operating period.

During the Darlington ISR, an assessment was completed [NK38-REP-03680-10204-R002, *Additional Analysis of DNGS ISR Fire Protection Related Issues*, January 12, 2015] that proposed a graded approach to addressing leakage in fuel oil piping. This graded approach recognizes the nuclear safety importance of the systems being supplied with fuel oil, and would allow these systems to be temporarily repaired while awaiting further corrective action, allowing the systems to remain in service. Action Request AR# 28175307 tracks implementation of the governance revision.

SECTION 4 - GI-7 PRIORITY DETERMINATION

	Deterministic Considerations			Probabilistic Considerations								
Safety Significance of Global Issue	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	**Overall Safety Significance Level**
	3	N/A	**3**	4	3	4	3	N/A	N/A	N/A	**3**	**3**

Rationale:

This issue is related to the Buried Piping Program. Addressing this Global Issue assures the ongoing fitness for service of Pickering buried piping for the operational life of the station. Safety functions can be impacted by the aged conditions of this piping and, as such, assurance of fitness for service is essential to ensure the adequacy of these safety functions.

This Global Issue has Safety Significance Level 3 for deterministic considerations with respect to

SECTION 4 - GI-7 PRIORITY DETERMINATION

Defence in Depth (E1) since assuring fitness for service prevents an adverse impact on a safety function (row 3 of Table E1 in the PSR2 Basis Document). Safety Significance Levels (E2) is considered not applicable because this Global Issue potentially impacts a nuclear safety barrier, whereas E2 primarily relates to issues that impact other objectives or are indirectly related to nuclear safety. Hence, the overall Safety Significance Level of 3 for deterministic considerations is dictated by the E1 categorization.

With respect to probabilistic considerations, this Global Issue is assigned Safety Significance Level 3 with respect to Defence in Depth (F2). This is because resolving this issue will prevent a partial loss of safety margin of a system important to safety in mitigating high probability events (frequency $>10^{-2}$/y). Similarly, the Safety Significance Level with respect to Plant Operability (F4) is also 3, since an extended period of plant shutdown as a result of fitness for service issues is expected to have a probability less than 0.01.

Safety Significance Level 4 is assigned for Reactor Safety – Core Damage Frequency (F1). The potential failure of safety related piping is insignificant in the Probabilistic Safety Assessment, and resolution of this Global Issue will ensure that the assumptions in the Probabilistic Safety Assessment regarding piping failure frequency remain valid. Therefore, the change in the Core Damage Frequency will be less than 10^{-7}/y, which corresponds to the fourth row of Table F1 in the PSR2 Basis Document, for which the Safety Significance Level is 4.

Resolution of this Global Issue is not expected to have any significant impact on Public Radiation Safety (F3) and accordingly this consideration is assigned Safety Significance Level 4. The other probabilistic considerations, i.e., Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7) are not applicable to this Global Issue. Hence, the overall Safety Significance Level of 3 for probabilistic considerations is dictated by F2 and F4 categorizations.

In summary, both deterministic and probabilistic considerations dictate that this Global Issue has Safety Significance Level 3. As noted, OPG is completing activities to ensure the fitness for service of Pickering buried piping for the operational life of the station.

SECTION 5 - GI-7 RESOLUTION PLAN

GI-7-RS1	Update the Buried Piping Program asset management plan [N-PLAN-04916-10002 R003, *Buried Piping Program Asset Management Plan*, January 2017] and risk ranking [P-MAN-04916-00001-R002, *Pickering Strategy Manual for Selection of Systems and Components for Inspection – Buried Piping*, March 2014] for the extended operating period. (SF2-14)
GI-7-RS2	Update governance to reflect a graded approach in the event that leakage in fuel oil piping occurs. This graded approach recognizes the nuclear safety importance of the systems being supplied with fuel oil, and would allow these systems to be temporarily repaired while awaiting further corrective action, allowing the systems to remain in service. This will involve document revision of Buried Piping Program Requirements [N-PROC-MA-0088-R003, *Buried Piping Program Requirements*, April 7, 2015]. (SF1-35)

B.8. GI-8 Completion / Updating of the Condition Assessments

SECTION 1 - GI-8 GLOBAL ISSUE SUMMARY					
The goal of GI-8, Completion/Updating of the Condition Assessments, is to confirm the completeness of the Pickering Condition Assessments (CAs) for the extended operating period. This Global Issue comprises two proposed Resolution Statements addressing four Gaps: two SF2 review task Gaps and two SF2 Additional Gaps. GI-8 is Safety Significance Level 2 based on deterministic and probabilistic defence-in-depth considerations as well as plant operability considerations. OPG has completed a significant amount (~95%) of CA work for the extended operating period. No issues have been found that significantly impact safety [P-REP-03680-00005 R001]. The proposed Resolution Plan comprises activities to complete and update the CAs for the piping systems and Commodity Groups for the extended operating period. Piping systems include many systems for which the CAs have been completed, e.g., the Heat Transport and Moderator Systems. Commodity Groups comprise components having common attributes encompassing all SSCs in Systems Important to Safety and Safe Operating Envelope systems. Recommendations resulting from updating the CAs will be assessed and included, as appropriate, in the CA action plans in the System and Component Health Reports per current governance. The final actions will also be tracked to completion as part of a process that will be created by OPG to track and report on progress to the CNSC. Completion of the proposed Resolution Plan will support and strengthen Level 1 defence-in-depth for the extended operating period.					
Safety Significance Level:	2	**Category:**	Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-8 ASSOCIATED GAPS	
SF2-12	Condition Assessments for in-scope piping systems are not complete for station operation to 2028[33]. ***Review Task #1 Actual Condition of SSCs*** **Associated Resolutions:** GI-8-RS1, GI-8-RS2
SF2-15	Updated Detailed Condition Assessments are not complete for Commodity Groups in the scope of PSR2 for station operation to 2028[33]. ***Review Task #1 Actual Condition of SSCs*** **Associated Resolutions:** GI-8-RS1, GI-8-RS2
SF2-AG4	An SF2 Gap related to knowledge of the actual condition of Structures, Systems, and Components Important to Safety and actions to address findings, was identified in [P-CORR-00531-05099, e-Doc 5295534, July 12, 2017]. **Associated Resolutions:** GI-8-RS2

SECTION 2 - GI-8 ASSOCIATED GAPS	
SF2-AG8	An SF2 Gap related to Obsolescence of Digital Controllers and a review of Critical Safety Parameters Monitoring Instrumentation was identified in [P-CORR-00531-05099, e-Doc 5295534, July 12, 2017]. The associated resolution addresses Item (b) of the reference. Item (a) is being addressed as described in [P-CORR-00531-05132, *Pickering Periodic Safety Review 2- Process for Addressing CNSC Identified Additional Gaps*, September 18, 2017]. **Associated Resolutions:** GI-8-RS1

SECTION 3 – GI-8 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains two SF2 Gaps and two SF2 Additional Gaps related to the Condition Assessments (CAs).

OPG has completed a significant amount (~95%) of CA work for the extended operating period. No issues have been found that significantly impact safety [P-REP-03680-00005 R001, *Pickering NGS PSR2 Safety Factor 2 Report – Actual Condition of Structures, Systems and Components Important to Safety*, March 2017].

The recommendations included in the Condition Assessments identify activities for current and extended operating life. The set of recommendations will be assessed and prioritized as per normal practice [N-PROC-MP-0060 R005B, OPG Nuclear Procedure, *Aging Management Process*, October 2015] associated with Aging Management assessments. When finalized, the set of actions will be tracked in System and Component Health Reports per current governance. The final actions will also be tracked to completion as part of a process that will be created by OPG to track and report on progress to the CNSC.

This overarching Global Issue will include the Irradiated Fuel Bay (IFB) Structures, Systems and Components; secondary side pressure retaining components; Deaerator and Deaerator Storage Tanks; Fuelling Machines and Fuelling Machine Bridge Ball Screws, as well as the Primary Heat Transport Auxiliary Piping Systems and Primary Heat Transport Valves.

The instrumentation and sensing devices used for CSPM have been assessed as part of the Condition Assessments of other systems, for example, under the Boiler Feed System for boiler level. Similarly, assessment of display and annunciation related components is included in systems such as Digital Control Computers, Boiler Steam and Water Systems, Electrical Systems etc.

As part of the Integrated Aging Management Program, the ongoing evaluation of the condition of critical SSCs, including the instrumentation related to CSPMs, is accomplished through the regular update of Condition Assessments. Critical components associated with CSPM are included in the Aging Management scope for PSR2.

SECTION 4 – GI-8 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	2	N/A	**2**	4	2	4	2	N/A	N/A	N/A	**2**	**2**

Rationale:

Addressing this Global Issue assures the completion of Condition Assessments for various systems and components to demonstrate fitness for service and good operating condition for the extended operating period. Safety functions can be impacted by the aged conditions of systems important to safety and, as such, completion of their Condition Assessment will identify required actions to ensure the equipment remains in good condition for the extended operating period. As discussed in Section 3 of this Global Issue, OPG has completed the majority of the Condition Assessments and no issues have been identified that significantly impact safety.

Nevertheless, this Global Issue has Safety Significance Level 2 for deterministic considerations with respect to Defence in Depth (E1), since ensuring fitness for service will preserve the integrity of the plant physical barriers (row 2 of Table E1 in the PSR2 Basis Document). Safety Significance Levels (E2) is considered not applicable because this Global Issue can have a direct impact on nuclear safety, whereas E2 primarily relates to issues without a direct impact on nuclear safety. Hence, the overall Safety Significance Level of 2 for deterministic considerations is dictated by the E1 categorization.

With respect to probabilistic considerations, this Global Issue is assigned Safety Significance Level 2 with respect to Table F2 in the PSR2 Basis Document. This is because resolving the issue preserves safety margins for systems important to safety in mitigating initiating events with a frequency $>10^{-2}$/y (row 3 of Table F2 in the PSR2 Basis Document). Similarly, the Safety Significance Level with respect to Plant Operability (F4) is also 2, because an extended period of plant shutdown as a result of fitness for service issues is expected to have a probability less than 0.1.

Safety Significance Level 4 is assigned to Core Damage Frequency (F1) and Public Radiation Safety (F3) since this Global Issue has an insignificant impact on these considerations. This Global Issue has no impact on the other probabilistic considerations, i.e., Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these considerations are not applicable.

In summary, both deterministic and probabilistic considerations dictate that this Global Issue has Safety Significance Level 2. As noted, OPG's existing programs address this issue on an ongoing basis to ensure the Condition Assessments are completed and updated.

SECTION 5 – GI-8 RESOLUTION PLAN	
GI-8-RS1	Complete and update Condition Assessments (CA) for the piping systems and commodity groups in PSR2 scope for station operation for the extended operating period. Resulting recommendations will be assessed and included, as appropriate, in the CA action plans in the System and Component Health Reports. OPG is actively progressing with this work. (SF2-12) (SF2-15) (SF2-AG8 Item (b)) This Resolution Statement includes/addresses GI-10, GI-20, GI-21, GI-22, GI-29, and GI-49 for Condition Assessments.
GI-8-RS2	Develop and implement a process to track and report aging-management-related actions from the Condition Assessment recommendations. (SF2-12) (SF2-15) (SF2-AG4) As the aging-management related actions will be tracked using the process described, cross-references from Global Issues whose Resolution Statements may generate such actions, are not included in this report.

B.9. GI-9 Seismic Capacity of the Conveyor Tube and Fuel Basket Stacking Arrangement

SECTION 1 - GI-9 GLOBAL ISSUE SUMMARY					
The goal of GI-9, Seismic Capacity of the Conveyor Tube and Fuel Basket Stacking Arrangement, is to confirm the seismic capacity of the Pickering 5-8 IFB conveyor tube and fuel basket stacking arrangement in the Pickering IFBs for the extended operating period. This Global Issue comprises one proposed Resolution Statement and one item requiring No Further Action, addressing two SF2 review task Gaps. GI-9 is Safety Significance Level 3 based on deterministic and probabilistic defence-in-depth considerations. The seismic capacity assessment of the Pickering 5-8 IFB conveyer tube has been completed [NK30-CALC-35260-00001 R000], demonstrating the adequacy of the design. No Further Action is required for this Gap. The proposed Resolution Plan comprises activities to complete the required assessment to support the current fuel basket stacking arrangements in the Pickering IFBs. Completion of the proposed Resolution Plan will support and strengthen Level 1 defence-in-depth for the extended operating period.					
Safety Significance Level:	3	**Category:**	Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-9 ASSOCIATED GAPS	
SF2-17	The seismic capacity of the current spent fuel basket stacking arrangements in the Pickering IFBs needs to be documented. ***Review Task #4 Spent Fuel Storage Facilities*** **Associated Resolutions:** GI-9-RS1
SF2-18	The seismic capacity of the Pickering 058 IFB conveyer tunnel needs to be documented. ***Review Task #4 Spent Fuel Storage Facilities*** • **Note – Per GI-9-NFA1, this Gap has been fully addressed.** **Associated Resolutions:** GI-9-NFA1

SECTION 3 - GI-9 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains two SF2 Gaps related to the seismic capacity of the Pickering 5-8 IFB conveyor tube and fuel basket stacking arrangement in the Pickering IFBs. As per SCR #s P-2013-05015 and P-2015-11143 and AR # 28182003, the seismic capacities of the current spent fuel basket stacking arrangements in the Pickering IFBs and the Pickering 5-8 conveyer

SECTION 3 - GI-9 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

tube are to be documented.

SECTION 4 - GI-9 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	3	N/A	**3**	N/A	3	N/A	N/A	N/A	N/A	N/A	**3**	**3**

Rationale:

As discussed in Section 5 of this Global Issue, for this Global Issue, the resolution of this Global Issue will support the current spent fuel basket stacking arrangements in the Pickering IFBs. The seismic capacity assessment of the Pickering 5-8 IFB conveyer tube has been completed demonstrating the adequacy of the design.

Regarding deterministic considerations, the Safety Significance Level determined from Table E1 in the PSR2 Basis Document is Safety Significance Level 3 since resolution of this issue confirms the capability of the safety function (first column, third row of Table E1 in the PSR2 Basis Document). Table E2 in the PSR2 Basis Document is assessed as not applicable because this Global Issue can have a direct impact on nuclear safety, whereas E2 primarily relates to issues without a direct impact on nuclear safety. The overall Safety Significance Level for deterministic considerations is 3.

Regarding probabilistic considerations, Defence in Depth (F2) is the dominant consideration because of the potential impact on a barrier. Safety Significance Level 3 is assigned to Defence in Depth (F2) on the basis that seismic qualification of the spent fuel basket stacking arrangements precludes a partial loss of safety on a secondary parameter, i.e., the bottom row of Table F2 in the PSR2 Basis Document. The most conservative Safety Significance Level for this row is selected. This Global Issue has no impact on the other probabilistic considerations, i.e., Core Damage Frequency (F1), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these considerations are not applicable.

In summary, the overall Safety Significance Level is 3. OPG has activities underway to fully address this issue.

SECTION 5 - GI-9 RESOLUTION PLAN	
GI-9-RS1	Complete the required assessment to support the current fuel basket stacking arrangements in the Pickering IFBs. This seismic related issue was noted in the response to Fukushima Action Item FAI 2.1.2. Additional investigation is required to support the current spent fuel basket stacking arrangements in the Pickering IFBs. (SF2-17)
GI-9-NFA1	The seismic capacity assessment of the Pickering 5-8 IFB conveyer tube has been completed [NK30-CALC-35260-00001 R000, OPG Engineering Calculation, *PNGSB Conveyor Tube Seismic Assessment*, March 2017], demonstrating the adequacy of the design. No further action is required. (SF2-18)

B.10. GI-10 IFB Condition

SECTION 1 - GI-10 GLOBAL ISSUE SUMMARY					
The goal of GI-10, IFB Condition, is to ensure the adequacy of the condition of the Pickering IFBs for the extended operating period. This Global Issue comprises one proposed Resolution Statement and one Cross Reference to GI-8, addressing two Gaps: one SF2 review task Gap and one SF4 review task Gap. GI-10 is Safety Significance Level 3 based on deterministic and probabilistic defence-in-depth considerations. The leakage from the IFB-B liner to the interspace is being tracked and OPG has already submitted a detailed action plan for addressing this issue [P-CORR-00531-04624, OPG Correspondence, *Response to CNSC Action Item 2014-48-5386 Status Update: CNSC Review of 2013 Groundwater Monitoring Results Report – Pickering B IFB Leak Mitigation*, February 26, 2016]. The status update of the project was provided in [P-CORR-00531-04865, OPG Correspondence, *Status Update: Pickering B Irradiated Fuel Bay Leak Mitigation Project #13-40703, Action Item 2014-48-5386*, November 17, 2016]. The proposed Resolution Plan comprises activities to complete the Pickering 5-8 IFB Leakage Mitigation Project to mitigate leaks from the IFB-B liner to the interspace. In addition, completion of the Condition Assessment of the IFB SSCs is cross-referenced to GI-8, Completion/Updating of the Condition Assessments.					
Safety Significance Level:	3	**Category:**	Engineering, Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-10 ASSOCIATED GAPS	
SF2-16	Action plans to correct the leakage in IFB-B are not complete. ***Review Task #4 Spent Fuel Storage Facilities*** **Associated Resolutions:** GI-10-RS1
SF4-2	Per Safety Factor 4 Review Task #9, there is a Gap with respect to the Aging Management practices of IFB facilities at Pickering NGS that is to specifically produce a CA for the Pickering 1-4 IFB SSCs and the Pickering Auxiliary IFB SSCs. It is noted that work to address this Gap is currently underway as part of the Pickering NGS Condition Assessments for the Pickering IFBs that will be addressed under Safety Factor Report 2, *Actual Condition of Structures, Systems and Components*. Since this work is not yet complete, this is identified as a Gap for Pickering PSR2. ***Review Task #9: Management of Aging for Spent Fuel Storage Facilities*** **Associated Resolutions:** GI-8-RS1

SECTION 3 - GI-10 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains two Gaps (one SF2 Gap and one SF4 Gap) that are related to the conditions of the IFBs.

The IFB-B leakage (CNSC Action Item 2014-48-5386) is being tracked by OPG. OPG has already submitted a detailed action plan for addressing this issue [P-CORR-00531-04624, OPG Correspondence, *Response to CNSC Action Item 2014-48-5386 Status Update: CNSC Review of 2013 Groundwater Monitoring Results Report – Pickering B IFB Leak Mitigation*, February 26, 2016]. OPG committed to provide the CNSC with a status update on Project # 13-40703 “Pickering B 90580 Irradiated Fuel Bay (IFB) Leak Mitigation” to address CNSC Action Item 2014-48-5386 by November 23, 2016. The status update of the project was provided in [P-CORR-00531-04865, OPG Correspondence, *Status Update: Pickering B Irradiated Fuel Bay Leak Mitigation Project #13-40703, Action Item 2014-48-5386*, November 17, 2016].

Work to assess the IFB SSCs is currently underway as part of the Pickering NGS Condition Assessments for the Pickering IFBs (see also GI-8).

SECTION 4 - GI-10 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								**Overall Safety Significance Level**
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	3	N/A	**3**	N/A	3	4	N/A	4	N/A	4	**3**	**3**

Rationale:

Resolution of this Global Issue will address leakage of the IFB liner to the interspace in IFB-B, as well as other aging-related and Condition Assessment issues for the IFBs. OPG has activities underway to address both aspects of this Global Issue.

Regarding deterministic considerations, Defence in Depth (E1) usually refers to barriers associated with the reactor. However, the IFBs also represent a physical barrier to the release of radioactive material from the station, so the Safety Significance Level is determined from Table E1 of the PSR2 Basis Document. On the basis that IFB issues, even liner leakage, do not impair the capability of safety provisions to effectively terminate an initiating event (first column of Table E1), Safety Significance Level 3 is selected. The last column of Table E1 is also relevant, as it refers to

SECTION 4 - GI-10 PRIORITY DETERMINATION

operational performance, for which Safety Significance Level 3 is also applicable since, from an operational perspective, improvements related to liner leakage are warranted. Table E2 is deemed not applicable, since this Global Issue can have a direct impact on nuclear safety, whereas E2 primarily relates to issues without a direct impact on nuclear safety. The overall Safety Significance Level for deterministic considerations is, therefore, 3.

Regarding probabilistic considerations, Defence in Depth (F2) is the dominant consideration due to the potential impact on a barrier to release. A Safety Significance Level of 3 is assigned on the basis that leakage into the interspace is at most only a partial loss of a barrier, so the bottom row of Table F2 is applicable. The most conservative Safety Significance Level for this row is selected, i.e., Safety Significance Level 3.

IFB leakage into the interspace is not expected to have any impact on Public Radiation Safety (F3), Occupational Radiation Safety (F5) or Environment (F7), but for conservatism, a Safety Significance Level of 4 is selected for these considerations.

As IFB issues do not affect the reactor core, Core Damage Frequency (F1) is not impacted. The potential for IFB events to contribute to the Large Release Frequency is addressed in the safety analysis program, so Table F1 is not applicable to this Global Issue. Plant Operability (F4) is not applicable either, since the issues associated with this Global Issue do not represent a loss of operating margin, which is the lowest condition for this consideration being assigned a Safety Significance Level. Emergency Preparedness (F6) is not applicable, since any minor IFB leakage to the interspace will not impact the response to a postulated initiating event.

In summary, the overall Safety Significance Level for this Global Issue is 3. Actions are in progress to address this Global Issue.

SECTION 5 - GI-10 RESOLUTION PLAN

GI-10-RS1	Complete the Pickering 5-8 IFB Leakage Mitigation Project [P-CORR-00531-04865, OPG Correspondence, *Status Update: Pickering B Irradiated Fuel Bay Leak Mitigation Project #13-40703, Action Item 2014-48-5386*, November 17, 2016] to mitigate leaks from IFB-B to the interspace. (SF2-16)
GI-10-XRF-GI-8-RS1	Complete the Condition Assessment of the IFB SSCs. (SF4-2)

B.11. GI-11 Fuel Management and Surveillance Software Upgrade

SECTION 1 - GI-11 GLOBAL ISSUE SUMMARY					
The goal of GI-11, Fuel Management and Surveillance Software Upgrade, is to ensure that CNSC Action Item 2016-OPG-8250 regarding the requirements for long-term core surveillance activities is addressed for the extended operating period. This Global Issue comprises one Acceptable Deviation, addressing one COP Review Gap. GI-11 is Safety Significance Level 4 based on deterministic safety significance levels considerations. OPG has provided a response to Action Item 2016-OPG-8250 [N-CORR-00531-18204] indicating that a status update will be provided with details of revised station documents, responses to suggestions for improvement, and a progress update on the fuel monitoring plan. The proposed Resolution Plan assesses this issue as an Acceptable Deviation because OPG is actively progressing completion of its commitment outside PSR2, and because of its very low Safety Significance.					
Safety Significance Level:	4	**Category:**	Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-11 ASSOCIATED GAPS	
COP-15	There are remaining issues from Generic Action Item (GAI) 01G01 *Fuel Management and Surveillance Software Upgrade* (AI 2016-OPG-8250). ***Pickering PSR2 Gap COP-15*** **Associated Resolutions:** GI-11-AD1

SECTION 3 - GI-11 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains one COP Review Gap related to Fuel Management and Surveillance Software. CNSC staff provided closure of Generic Action Item (GAI) 01G01, *Fuel Management and Surveillance Software Upgrade* and opened AI 2012-OPG-3465 to track associated actions. This AI was subsequently closed and a new AI (2016-OPG-8250) was opened to track the CNSC staff request that relevant OPG governance and/or station documents be revised to explicitly capture requirements for the long-term core surveillance activities identified. OPG has provided a response to this Action Item [N-CORR-00531-18204, OPG Correspondence, *Darlington and Pickering NGS: Fuel Management Surveillance Software Upgrade – New Action Item 2016-OPG-8250*, September 16, 2016] indicating that a status update will be provided with details of revised station documents, responses to suggestions for improvement, and a progress update on the fuel monitoring plan. This issue applies to Pickering Units 1,4 and Units 5-8.

SECTION 4 - GI-11 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	N/A	4	**4**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**4**

Rationale:

Resolution of this Global Issue will confirm the adequacy of certain approximations in the Fuel Management and Surveillance Software. Actions to address this Global Issue are underway.

Regarding deterministic considerations, this Global Issue is not associated with a physical barrier, so Defence in Depth (E1) is not applicable. For Safety Significance Levels (E2), Safety Significance Level 4 is determined to be applicable, since resolution of this issue may help identify areas that need more attention, in this case the station core model or fuel management software. Therefore, an overall Safety Significance Level of 4 is selected for deterministic considerations.

For this Global Issue, the probabilistic considerations are not applicable. This Global Issue has no impact on Core Damage Frequency (F1) or probabilistic Defence in Depth (F2), nor does it impact Plant Operability (F4), Public Radiation Safety (F3), Occupational Radiation Safety (F5), Emergency Preparedness (F6) or Environment (F7). The issue will result in confirmation of or enhancements to software that is already in service and is not addressing a deficiency. Therefore, probabilistic considerations have no impact on the overall Safety Significance Level.

In summary, the overall Safety Significance Level is 4. OPG is addressing this issue outside of PSR2.

SECTION 5 - GI-11 RESOLUTION PLAN

GI-11-AD1	OPG is actively progressing completion of the OPG commitment to provide additional information to address Action Item 2016-OPG-8250 (AR # 28193296) on fuel management and surveillance software, outside of PSR2. This issue is related to providing additional information on the Fuel Management and Surveillance Software and as per the very low safety significance (Safety Significance Level 4); it is assessed as an Acceptable Deviation. (COP-15)

B.12. GI-12 Extending the Environmental Qualification of Equipment

SECTION 1 - GI-12 GLOBAL ISSUE SUMMARY					
The goal of GI-12, Extending the Environmental Qualification of Equipment, is to confirm the environmental qualification of components for the extended operating period for components whose qualification would otherwise expire (referred to as life-limited components). This Global Issue comprises one proposed Resolution Statement, addressing one SF3 review task Gap. GI-12 is Safety Significance Level 3 based on deterministic and probabilistic defence-in-depth considerations. The proposed Resolution Plan comprises activities to update Environmental Qualification Assessments (EQAs) for life-limited components to support the extended operating period. Completion of the proposed Resolution Plan will support and strengthen Level 3 defence-in-depth for the extended operating period.					
Safety Significance Level:	3	**Category:**	Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-12 ASSOCIATED GAPS	
SF3-1	Per Review Task #3, the Environmental Qualification Program N-PROG-RA-0006, *Environmental Qualification Program* requires that whenever equipment on the EQL approaches the end of its qualified life, action must be taken to sustain the qualified status of that equipment regardless of what the station current life is taken to be. Hence, all EQAs will need to be re-assessed to ensure qualification is maintained in order to support continued operation of Pickering NGS beyond 2020. The current Environmentally Qualified life of all Pickering NGS SSCs may not necessarily extend to 2028[33] and a full review of Environmentally Qualified life-limited components impacted by operation past 2020 will need to be undertaken prior to life extension of Pickering NGS. This is therefore identified as a gap exists for Pickering PSR2. It is noted that work to address this gap is currently underway as part of the update of Pickering NGS Condition Assessments for Safety-Related Systems and Life Cycle Management Plans for Major Components. ***Review Task #3 Qualification of Installed Equipment*** **Associated Resolutions:** GI-12-RS1

SECTION 3 - GI-12 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains one SF3 Gap related to the Environmental Qualification of equipment. A review of Environmentally Qualified life-limited components impacted by operation past 2020 will need to be undertaken. (See GI-1, GI-2, GI-3, GI-4 and GI-8).

SECTION 4 - GI-12 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	3	N/A	**3**	4	3	N/A	N/A	N/A	N/A	N/A	**3**	**3**

Rationale:

Resolution of this Global Issue will complete Environmental Qualification re-assessments to ensure the equipment will perform its safety functions in support of extended operation. OPG is actively progressing this work.

Regarding deterministic considerations, the Safety Significance Level determined from Table E1 in the PSR2 Basis Document is 3. This is because ensuring Environmental Qualification for extended operation will ensure the capability of safety provisions to effectively terminate an initiating event (first column, third row in Table E1 in the PSR2 Basis Document) and the issue does not affect the safety function capability for more than one level of protection (second column, third row in Table E1 in the PSR2 Basis Document). Safety Significance Levels (E2) is considered not applicable, since this Global Issue has a direct nuclear safety impact, whereas E2 primarily relates to issues that impact other objectives or are indirectly related to nuclear safety. The overall Safety Significance Level for deterministic considerations is 3.

Regarding probabilistic considerations, Defence in Depth (F2) is assigned Safety Significance Level 3. This is on the basis that confirming Environmental Qualification of the equipment associated with Systems Important to Safety precludes a reduction in the reliability of a System Important to Safety in responding to events of frequency $>10^{-3}$/y, or reduction in the reliability of a back-up system in responding to events of frequency $> 10^{-2}$/y. Safety Significance Level 4 is assigned for Reactor Safety – Core Damage Frequency (F1). Potential failure of equipment is accounted for in the Probabilistic Safety Assessment, and resolution of this Global Issue will ensure that the assumptions in the Probabilistic Safety Assessment regarding equipment failure frequency remain valid. Therefore, the change in the Core Damage Frequency will be less than 10^{-7}/y, which corresponds to the fourth row of Table F1 in the PSR2 Basis Document, for which the Safety Significance Level is 4.

This Global Issue has no impact on the other probabilistic considerations, i.e., Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these considerations are not applicable.

In summary, the overall Safety Significance Level is 3. OPG has activities underway to address this

SECTION 4 - GI-12 PRIORITY DETERMINATION
issue.

SECTION 5 - GI-12 RESOLUTION PLAN	
GI-12-RS1	Complete EQA re-assessments to support the extended operating period. OPG is actively progressing this work in support of extended operation at Pickering NGS. (SF3-1)

B.13. GI-13 Seismic Qualification - N289

SECTION 1 - GI-13 GLOBAL ISSUE SUMMARY					
The goal of GI-13, Seismic Qualification – N289, is to confirm that seismic qualification is adequately addressed with respect to the CSA N289 series of standards. This Global Issue comprises four Acceptable Deviations and one item requiring No Further Action addressing four Gaps: three SF3 code review Gaps and one COP Review Gap that also originates from a code review. GI-13 is Safety Significance Level 4 based on deterministic and probabilistic defence-in-depth considerations as well as core damage frequency considerations. Pickering NGS meets the intent of the codes and standards that were in place at the time of original design and construction. The Gaps related to modern requirements for seismic analysis, seismic testing procedures and seismic instrumentation requirements are resolved as three Acceptable Deviations based on the results of the PSA based Pickering Seismic Margin Assessments conducted as part of the Fukushima Integrated Action Plan, relevant assessments performed for Darlington, and their very low Safety Significance. The COP Review Gap identified with respect to the minimum number of cycles used for seismic fatigue analysis is assessed to require No Further Action for Units 5-8 because a review of actual design reports confirmed that the number of cycles used and continued to be used in seismic analyses meet or exceed CSA N289.3 requirements. For Units 1,4, the Gap with respect to the minimum number of cycles is assessed as an Acceptable Deviation because the systems and components are designed to American Society of Mechanical Engineers (ASME) requirements, including required cycles for fatigue analysis, and the Seismic Margin Assessment demonstrates that the risk associated with seismic hazards is sufficiently low.					
Safety Significance Level:	4	**Category:**	Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-13 ASSOCIATED GAPS	
SF3-2	For N289.3-10, *Design Procedures for Seismic Qualification of Nuclear Power Plants* there is a gap associated with Safety Factor 3. Clause 4.4.4.5 of CSA N289.3-10 states: “The power spectral density (PSD) function of each time-history shall be calculated and shown to not have any significant gaps in energy over the frequency intervals outlined in Table 2….” The calculation of PSD is not addressed in the Pickering A or B PRA Based SMAs. The Pickering NGS A PRA Seismic Guide and the OPG PRA Guide do not identify any requirements for PSD. Also, evidence in the form of a calculation for time histories which represent the design ground motion was not found (which is a precursor for the PSD calculation). The lack of evidence of calculated time histories was also identified as a gap in the Darlington ISR (ISR Issues #D352 and #D617 – Documented evidence in the form of a calculation to show that the generated time history correctly represents the design ground response spectrum within the prescribed requirements has not been provided). The closure reference for #D352 and #D617 makes use of the detailed assessment performed in NK38-REP-03680-10224 R000 which is specific to Darlington. A similar assessment for Pickering NGS could not be found. As a result, there is a gap for PSR2 to provide similar evidence to show that: a) the generated time history used within seismic analyses of Safety-

SECTION 2 - GI-13 ASSOCIATED GAPS	
	Related Systems correctly represents the design ground response spectrum for the Pickering site in compliance with N289.3-10, and b) the PSD function of each time-history has been calculated and shown to not have any significant gaps in energy over the frequency intervals. ***Code Review N289.3-10*** **Associated Resolutions:** GI-13-AD1
SF3-3	For N289.4-12, *Testing Procedures for Seismic Qualification of Nuclear Power Plants Structures, Systems, and Components* there is a Gap associated with Safety Factor 3. Station-specific documents (including the Darlington seismic design guide, Darlington Reports and Darlington-specific technical specifications for seismic qualification) were used as the basis for compliance in the clause-by-clause Darlington code refresh review for clauses 4.2.1, 4.2.2.2, 4.2.3.1, 4.2.5, 4.3.2, 5.2.2.2.5, 5.7, 5.8.1, 5.8.1.2, 7.2.1, 7.7.1, 7.7.4 and 8.2. Pickering-specific seismic design guides, reports and technical specifications that are equivalent to those used to demonstrate Darlington compliance with the changes made in CSA N289.4-12 were identified. However, a detailed review to confirm that the Pickering-specific documents fully comply with the requirements of the clauses listed above is needed. As a result, this is a PSR2 Gap. ***Code Review N289.4-12*** **Associated Resolutions:** GI-13-AD2
SF3-4	For N289.5-12, *Seismic Instrumentation Requirements for Nuclear Power Plants and Nuclear Facilities* there is a gap associated with Safety Factor 3. Darlington ISR Issues #D622, D623 and D624 require no further action for Darlington as they were either classified as Acceptable Deviations or were closed. However, the issues are identified as a PSR2 gap for the following reasons: (Note: These gaps are closely related and are therefore identified as a single PSR2 gap.) • Darlington ISR Issue #624 refers to specific Darlington instrumentation in order to classify the gaps as Acceptable Deviations. It must be demonstrated that Pickering seismic instruments have the same capabilities as the Darlington instruments (fleet-wide or Pickering-specific standards that would ensure that the Pickering seismic instruments have the same capabilities as the Darlington instruments could not be found). Therefore, this is identified as a gap for PSR2. • Darlington ISR Issue #D622 was deemed to be of low safety significance. The same rationale may apply at Pickering, but first it must be demonstrated that Pickering has the same set up of seismic instruments as Unit 0 at Darlington. Therefore, this is identified as a gap for PSR2. • Darlington ISR Issue #D623 was deemed to be of low safety significance. The same rationale may apply at Pickering, but first it must be demonstrated that similar accelerometers are used at Pickering, and that their locations are not affected by strong ambient vibration. Therefore, this is identified as a gap for PSR2. ***Code Review N289.5-12***

SECTION 2 - GI-13 ASSOCIATED GAPS	
	Associated Resolutions: GI-13-AD3
COP-17	A review that considers the minimum number of cycles used for seismic fatigue analysis has not been completed for the level of compliance of Pickering NGS plant structures supporting the operation of Pickering reactors with CSA N289.3- M81, *Design Procedures for Seismic Qualification of CANDU Nuclear Power Plants*, Clause 5.13.2 in the context of extended operation. ***Pickering PSR2 Gap COP-17*** **Associated Resolutions:** GI-13-AD4, GI-13-NFA1

SECTION 3 - GI-13 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains four Gaps (three SF3 Gaps and one COP Review Gap) that are related to the CSA N289 series (seismic qualification).

SECTION 4 - GI-13 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	4	N/A	**4**	4	4	N/A	N/A	N/A	N/A	N/A	**4**	**4**

Rationale:

This Global Issue relates to conformance with the safety-significant requirements of the CSA N289 series of standards on seismic qualification. The proposed Resolution Plan for this Global Issue comprises four Acceptable Deviations and one resolution with No Further Action.

Regarding deterministic considerations, the Safety Significance Level determined from Table E1 in the PSR2 Basis Document is 4, as the proposed Resolution Plan rationale shows that this issue does not affect a safety function (first column, row 4 of Table E1 in the PSR2 Basis Document). Safety Significance Levels (E2) is assessed as not applicable since this Global Issue has a direct nuclear

SECTION 4 - GI-13 PRIORITY DETERMINATION

safety impact, whereas E2 primarily relates to issues without a direct impact on nuclear safety. The overall Safety Significance Level for deterministic considerations is 4.

Regarding probabilistic considerations, the gaps associated with this Global Issue are analytical and/or related to instrumentation, testing and documentation, and their resolution does not impact the outcome of the Seismic PSA. Therefore, Safety Significance Level 4 is selected for Core Damage Frequency (F1), corresponding to a change in core damage frequency less than 10^{-7}/y. Defence in Depth (F2) is assigned Safety Significance Level 4 since this Global Issue has no significant impact on safety margin (refer to Table F2 in the PSR2 Basis Document). Given the nature of the gaps comprising this Global Issue, its resolution will have no impact on Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these considerations are not applicable.

In summary, the overall Safety Significance Level is 4.

SECTION 5 - GI-13 RESOLUTION PLAN

GI-13-AD1	The time-history method is a typical method for seismic qualification that has been employed at Pickering NGS. Time-history ground motion inputs at Pickering NGS were established based on the requirements of CSA N289.3-M81. [NA44-REP-02004-0119, Seismic Soil-Structure Interaction Analysis of Pickering NGS A Reactor Building, March 1996; P-REP-25140-00001-R02, Pickering Nuclear Vacuum Building Seismic Analysis, August 2010; NK30-REP-21 001-00002, Reactor Building Seismic Analysis, February 2012]. New power spectral density (PSD) requirements are stipulated in Clause 4.4.4.5 of the most recent version of the Standard (N289.3-10). However, in accordance with Clause 5.4 of CSA N289.1-08 R2013, an acceptable method of re-evaluating existing Nuclear Plants for seismic considerations is Seismic PSA. The Pickering NGS seismic qualification design response spectra were assessed to be appropriate and adequate as part of the Pickering NGS 1,4 and 5-8 Seismic Margin Assessments conducted as part of the Pickering A and Pickering B Probabilistic Safety Assessments [P-REP-03611-00006-R000, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014] and reviewed and concurred by the CNSC staff in [P-CORR-00531-04875, *Pickering NGS: Probabilistic Risk Assessment Based Seismic Margin Assessment,* November 2016]. In addition, the seismic spectra for Pickering and Darlington were prepared using similar methodologies, and the Darlington spectrum results were shown to be adequate in comparison with the new power spectral density requirements [NK38-REP-03680-10224 *Spectrum-enveloping N289.3 Code Compliance of Darlington NGS Seismic Time Histories,* July 25, 2014]. For these reasons, and as per the very low safety significance (Safety Significance Level 4), this is assessed as an Acceptable Deviation. (SF3-2)
GI-13-AD2	With respect to CSA N289.4-12 Testing Procedures for Seismic Qualification of Nuclear Power Plants, similar to the assessment conducted for Darlington as outlined in [P-REP-03680-00004 PNGS PSR2 Code and Standard Reviews for Safety Factors 2, 3 and 4, July 13, 2016], OPG's Aging Management governance

SECTION 5 - GI-13 RESOLUTION PLAN	
	[N-PROG-MP-0008-R006, Integrated Aging Management, April 29, 2016] applies equally for Pickering NGS, and this ensures that aging degradation effects are considered for Pickering equipment impacted by this Standard. In addition, the robustness of the Equipment Reliability Program at Pickering [N-PROG-MA-0026 Equipment Reliability, May 26, 2016], and the results of the Pickering Seismic Margin Assessments conducted as part of the Pickering A and Pickering B Probabilistic Safety Assessments [P-REP-03611-00006-R000, Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan, April 30, 2014] confirm that the original design and seismic qualification of Pickering NGS provides an adequate level of safety from the earthquake hazard at the Pickering NGS site. OPG's commitment [N-CORR-00531-05661, Design Codes and Standards Effective Dates for OPG Nuclear Fleet, April 2012] to using CSA N289.4-12 for testing procedures for seismic qualification of nuclear power plant SSCs will ensure that the requirements will be followed. Furthermore, OPG governance is in place to ensure that CSA N289.4 is followed for seismic qualification of SSCs at OPG Nuclear Facilities [N-STD-MP-0025, *General Requirements For Seismic Qualification of OPG Nuclear Facilities*, October 27, 2016; Section 1.6]. As described in Sections 1.7.1 to 1.7.8 of N-STD-MP-0025, administrative controls have been developed to ensure that seismic qualification of SSCs performing safety-related functions during and following an earthquake is maintained for the life of the facility. For these reasons, and as per the very low safety significance (Safety Significance Level 4), this is assessed as an Acceptable Deviation. (SF3-3)
GI-13-AD3	Since the time of the Darlington NGS ISR, OPG has installed in-plant seismic instrumentation to monitor seismic activity at Pickering NGS (and at Darlington) in order to meet the intent of CSA standard N289.5-M91 [NK30-DM-61150-10001, *Pickering Nuclear: Seismic Monitoring* System, September 2013; N-GUID-02004-10000-R00, *Seismic Monitoring of OPG Nuclear Generating Stations*, December 2010]. Also, OPG has established procedures - Abnormal Incidents Manuals - that detail station response to earthquakes. Clear responsibilities are established to support monitoring and post-seismic response to an event [NK30-AIM-058-09013-6.0, *Abnormal Incident Manual: Seismic/Common Mode Event*; NA44-AIM-014-09013-06, *Abnormal Incident Manual: Seismic Event*]. Darlington ISR Issues #D622, D623 and D624 require no further action for Darlington as they were either classified as Acceptable Deviations or were closed. The Pickering Seismic Monitoring System was installed in 2012/2013 with the intent to meet the requirements of N298.4-M91, the same as those for Darlington seismic instrumentation; the rationales for acceptable deviations applied for Darlington NGS also apply to Pickering NGS. OPG is also a contributor to the operation of the Southern Ontario Seismic Network (SOSN) which provides detailed free-field seismic records covering Southern Ontario. These systems support in-plant monitoring of the station's response to seismic events. The results of the Pickering Seismic Margin Assessments conducted as part of the Pickering A and Pickering B Probabilistic Safety Assessments [P-REP-03611-00006-R000, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan,* April 30, 2014] demonstrate the adequacy of the instrumentation and response to a seismic event at Pickering NGS. For these reasons, and as per the very low

SECTION 5 - GI-13 RESOLUTION PLAN	
	safety significance (Safety Significance Level 4), this is assessed as an Acceptable Deviation. (SF3-4)
GI-13-AD4	[Units 1,4] Pickering Units 1,4 Class 1 systems and components are designed to ASME Code Section III which betters the CSA N289.3 requirement, including required cycles for fatigue analysis. [For example: SR-30-33126-1, *Primary Heat Transport System (Stress Report) Feeder Pipes Units 5 to 8*, October 1982; NA44-DS-33126-00005-R00, *Pickering 'A' – Design Specification For Primary Heat Transport System (PHTS) Feeders For Units 1 and 4,* January 2009; NA44-REP-31100-2.0148, *Pickering GS 'A' Units 1 and 2 LSFCRP Feeder Connection Stress Analysis (West End),* August 1985]. Furthermore, Seismic Margin Assessment is an accepted method for assessing seismic qualification. The Pickering A seismic design basis [NA44-REP-02004-0073, *Seismic Assessment of Pickering 'A' Nuclear Generating Station*, February 1998; NA44-02004-0346-R1, *Seismic Margin Analysis Of Primary Heat Transport Main Circuit And Main Steam Piping At Pickering NGS A*, October 1997; NA44-REP-02004-0344-R1, *Seismic Margin Assessment Of Calandria And Fuelling Machine*, October 1997] was established using the EPRI Seismic Margin Assessment (SMA) methodology [Electric Power Research Institute, *A Methodology for Assessment of Nuclear Power Plant Seismic Margin*, Report NP-6041-SL, Revision 1, August 1991]. The SMA-based Probabilistic Safety Assessment for Pickering Units 1,4 [NA44-REP-03611-00022 R000, *PRA-Based Seismic Margin Assessment of PNGS-A*, January 2014] demonstrates that risk associated with seismic hazard is sufficiently low. For continuing analysis of potential new modifications, the requirements of CSA N289.3-10 Clause 5.13.2 would be met or bettered, consistent with the modelling methodology in place at OPG for such work as noted above. For these reasons, and as per the very low safety significance (Safety Significance Level 4), this is assessed as an Acceptable Deviation for Pickering 1,4. (COP-17)
GI-13-NFA1	[Units 5-8] With respect to the CSA N289.3-10 Clause 5.13.2 requirement on the minimum number of cycles used for seismic fatigue analysis, for Pickering 5-8, seismic structural analysis codes/modelling better the CSA N289.3-10 Clause 5.13.2 requirements for minimum number of cycles used for seismic fatigue analysis [OPG Memorandum, NK30-REF-68000-0476807, *Disposition of Continued Operations – 102 Action AR 28134792-07*, September 2013]. For continuing analysis of potential new modifications, the requirements of CSA N289.3-10 Clause 5.13.2 would be met or bettered, consistent with the modelling methodology in place at OPG for such work [DG-30-68000-2 R1, *Pickering NGS B Seismic Qualification of Safety Related Systems*]. No further action is required for Pickering 5-8. (COP-17)

B.14. GI-14 Environmental Qualification Program Issues

SECTION 1 - GI-14 GLOBAL ISSUE SUMMARY					
The goal of GI-14, Environmental Qualification Program Issues, is to ensure that complete Environmental Qualification documentation is in place for the extended operating period. This Global Issue comprises one item assessed as requiring No Further Action and one Acceptable Deviation, addressing two SF3 Audit and Self-Assessment Gaps. GI-14 is Safety Significance Level 4 based on deterministic safety significance levels considerations. CNSC staff has confirmed that the Action Notice on the Environmental Qualification documentation backlog has been completed by OPG [P-CORR-00531-04874]. For this reason, the proposed Resolution Plan assesses the documentation backlog Gap as requiring No Further Action. The proposed Resolution Plan also comprises activities in progress to revise the Environmental Qualification Assessment for Tefzel cables (AR # 28170757). This issue is related to an Environmental Qualification Assessment documentation update and, as per the very low Safety Significance, it is assessed as an Acceptable Deviation.					
Safety Significance Level:	4	**Category:**	Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-14 ASSOCIATED GAPS	
SF3-5	The Environmental Qualification documentation backlog (e.g., Document Change Requests for Environmental Qualification Assessments) increased from 9% in Q4 2013 to 14% in Q4 2014. As a result, CNSC staff requested that OPG assess and create a corrective action plan to ensure that Environmental Qualification information remains current and more specifically to reduce and manage the document revision backlog. This is a Gap for PSR2 since the CNSC identified this issue in an Action Notice following a regulatory inspection and the associated action (AR#28179009) is due to be completed by Q3 2016. ***Audit and Self-Assessment Reviews*** • **Note – Per GI-14-NFA1, this Gap has been fully addressed.** **Associated Resolutions:** GI-14-NFA1
SF3-6	Pickering NGS is in non-compliance with N-PROC-RA-0044, *Environmental Qualification Assessment* for not correcting the documentation discrepancy for Unit 5-8 Vertical Flux Detector Tefzel cables with justification for a new qualified life value. As a result, CNSC staff requested that OPG revise the Environmental Qualification Assessment for Tefzel cables to reflect the change of qualified life of the Vertical Flux Detectors. This is a Gap for PSR2 since the CNSC identified this issue in an Action Notice following a regulatory inspection and the associated action (AR#28170757) is due to be completed by Q4 2016. ***Audit and Self-Assessment Reviews*** **Associated Resolutions:** GI-14-AD1

SECTION 3 - GI-14 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains two SF3 Gaps related to the Environmental Qualification Program.

CNSC staff identified the issue on the Environmental Qualification documentation backlog in an Action Notice (AN1) following a regulatory inspection [P-CORR-00531-04483, CNSC Correspondence, e-Doc 4766363, *Pickering NGS: CNSC Type II Compliance Inspection Report: PRPD-2015-005, Environmentally Qualified Equipment Inspection, New Action Item 2015-48-6459*, June 3, 2015]. Following implementation of corrective actions, this Action Notice (AN1) was subsequently confirmed complete by CNSC staff [P-CORR-00531-04874, e-Doc 5109031, *Pickering NGS: Followup to OPG Response to CNSC Type II Compliance Inspection: Environmentally Qualified Equipment, Action Item 2015-48-6459*, November 4, 2016].

SECTION 4 - GI-14 PRIORITY DETERMINATION

Safety Significance of Global Issue	**Deterministic Considerations**			**Probabilistic Considerations**								**Overall Safety Significance Level**
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	N/A	4	**4**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**4**

<u>Rationale:</u>

This Global Issue is related to an update of Environmental Qualification Assessment documentation, and is being addressed by OPG.

Regarding deterministic considerations, this Global Issue is not associated with a physical barrier, so Defence in Depth (E1) is not applicable. Safety Significance Levels (E2) is assigned Safety Significance Level 4 since resolution of this issue “may help identify areas that need more attention”, in this case the Environmental Qualification Assessment documentation update. Therefore, Safety Significance Level 4 is selected for deterministic considerations.

This Global Issue has no direct impact on the probabilistic considerations, i.e., Core Damage Frequency (F1), Defence in Depth (F2), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) or Environment (F7). Therefore, probabilistic considerations are not applicable.

SECTION 4 - GI-14 PRIORITY DETERMINATION
In summary, the overall Safety Significance Level is 4. OPG is addressing this issue.

SECTION 5 - GI-14 RESOLUTION PLAN	
GI-14-AD1	Revision of the EQA for Tefzel cables is in progress (AR # 28170757). Visual inspection of the Vertical Flux Detector cables for Units 5-8 and review of ten sample EQAs for extent of condition have been completed. The revision of the EQA [NK30-EQA-31740-10000-R001, OPG Environmental Qualification Assessment, *HESIR Flux Detector Assembly*] is being actively progressed outside of PSR2. This issue is related to an EQA documentation update and as per the very low safety significance (Safety Significance Level 4); it is assessed as an Acceptable Deviation. (SF3-6)
GI-14-NFA1	The Action Plan (AR # 28179009) for Environmental Qualification Assessments (EQAs) to manage the document revision backlog is complete. The related CNSC Action Notice (AN1) was subsequently confirmed complete by CNSC staff [P-CORR-00531-04874, e-Doc 5109031, *Pickering NGS: Followup to OPG Response to CNSC Type II Compliance Inspection: Environmentally Qualified Equipment, Action Item 2015-48-6459*, November 4, 2016]. No further action is required. (SF3-5)

B.15. GI-15 Governance Issues

SECTION 1 - GI-15 GLOBAL ISSUE SUMMARY					
The goal of GI-15, Governance Issues, is to ensure that Gaps on various Governance issues are addressed for the extended operating period. This Global Issue comprises two items assessed as requiring No Further Action and one Acceptable Deviation, addressing four Gaps: one SF1 code review Gap [CSA N290.8-15], one SF4 review task Gap, one SF5 Gap from additional review findings and one SF5 Additional Gap. GI-15 is Safety Significance Level 4 based on deterministic safety significance levels considerations. The OPG Governance and the proposed Resolution Plans relevant to the identified Gaps are summarized as follows: • The Gap related to obsolescence of services or supplies external to the plant is addressed in OPG-PROC-0058, which specifies that any potential disruptions to the supply of items and/or services that may adversely impact OPG shall be addressed in a consistent and expedient manner. The proposed Resolution Plan, therefore, assesses this Gap as requiring No Further Action. • The Gap related to controls on the introduction of supplier-provided digital equipment into OPG nuclear power plants is addressed through processes outlined in N-PROG-MP-0001. The proposed Resolution Plan, therefore, assesses this Gap as an Acceptable Deviation. • The Gaps related to the use of the best estimate approach or a similarly conservative approach for analysis of operational events is addressed in Nuclear Safety Analysis governing document N-MAN-03600-10005-R006. These Gaps are assessed as requiring No Further Action because of their very low Safety Significance (Level 4) and because they are being addressed outside of PSR2.					
Safety Significance Level:	4	**Category:**	Programmatic	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-15 ASSOCIATED GAPS	
SF4-1	The conclusion of Safety Factor 4 Review Task #7 is that programs for timely detection and mitigation of aging mechanisms and/or aging effects, including obsolescence of technology, have been established. However, N-STD-MA-0024, *Obsolescence Management* does not explicitly address obsolescence of services or supplies external to the plant. This is therefore identified as a Gap for Pickering PSR2. ***Review Task #7 Detection and Mitigation of Aging Systems*** • **Note – Per GI-15-NFA1, this Gap has been fully addressed.** **Associated Resolutions:** GI-15-NFA1
SF5-7	The Darlington Integrated Implementation Plan (IIP) [OPG Report, NK38-REP-03680-10185 R002, *Darlington NGS Integrated Implementation Plan (IIP)*, April 30, 2015] identified a Gap

SECTION 2 - GI-15 ASSOCIATED GAPS	
	(IIP-OI 055) related to use of the best estimate approach for analysis of operational events at Darlington NGS. The action for Darlington (AR 28175247, Target Completion Date Q1 2020) was to revise OPG governing document N-MAN-03600-10005, *Nuclear Safety Analysis*, to require the use of the best estimate approach or a similarly conservative approach for analysis of operational events. This action is also applicable for Pickering NGS and is therefore a Gap for Pickering PSR2. ***Additional Review Findings in Section 4.4 of Safety Factor 5 Report*** • **Note – Per GI-15-NFA2, this Gap has been fully addressed.** **Associated Resolutions:** GI-15-NFA2
SF1-34	Clause 4.7 of N290.8-15 mandates that the technical specification requires the supplier to identify and describe all digital items included in their equipment. In the event that the use of digital items is identified by OPG in advance of issuing a Request for Proposal or Request for Quotation, existing OPG procedures are adequate for ensuring that requirements related to digital items are documented in the technical specification. However, a requirement for a supplier to self-identify whether their product contains any digital items is not reflected in OPG governing documents This has therefore been identified as a PSR2 Gap. ***Code Review N290.8-15*** **Associated Resolutions:** GI-15-AD1
SF5-AG3	An SF5 Gap related to implementation of a Best Estimate Analysis or similarly conservative approach for Operational Events, or justification for the continued use of the existing conservative approach, was identified in [P-CORR-00531-05090, e-Doc 5289137, June 30, 2017]. **Associated Resolutions:** GI-15-NFA2

SECTION 3 - GI-15 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue consolidates four Gaps on various OPG governance issues. This includes one SF4 Gap, one SF5 Gap, one SF1 Gap and one SF5 Additional Gap.

SECTION 4 - GI-15 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	N/A	4	**4**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**4**

Rationale:

This Global Issue includes minor issues related to governance updates.

Regarding deterministic considerations, this Global Issue is not associated with a physical barrier, so Defence in Depth (E1) is not applicable. Safety Significance Levels (E2) is assigned Safety Significance Level 4 since resolution of this issue "may help identify areas that need more attention", in this case governance updates. Therefore, Safety Significance Level 4 is selected for deterministic considerations.

With respect to probabilistic considerations, this Global Issue has no impact on Core Damage Frequency (F1) or Defence in Depth (F2), nor does it impact Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) or the Environment (F7). Therefore, probabilistic considerations are not applicable.

In summary, the overall Safety Significance Level is 4.

SECTION 5 - GI-15 RESOLUTION PLAN

GI-15-AD1	OPG has established stringent controls on the introduction of digital equipment at its nuclear power plants. Technical specifications are prepared when performing design modifications, non-identical component replacements and item equivalencies. These processes, as outlined in N-PROG-MP-0001 *Engineering Change Control*, invoke detailed procedures which ensure appropriate specification of requirements with respect to digital equipment and embedded digital items, and include checks and confirmation of the form of equipment supplied via these processes. To add additional defence to the existing provisions, a Documentation Change Request has been filed (#140057) to update specification preparation governance to require suppliers to identify and describe digital items in equipment provided. The implementation of this change will be managed outside of PSR2. As per the very low safety significance (Safety

SECTION 5 - GI-15 RESOLUTION PLAN	
	Significance Level 4), it is assessed as an Acceptable Deviation. (SF1-34)
GI-15-NFA1	Obsolescence of services and supplies for any reason (business discontinuation/interruption, failure of a qualification audit, low volume interactions) is addressed by OPG-PROC-0058 [OPG-PROC-0058 R011, OPG Procedure, *Procurement Activities*, March 2017]. Section 1.20.5 of OPG-PROC-0058 specifies that any potential disruptions to the supply of items and/or services that may adversely impact OPG shall be addressed in a consistent and expedient manner. For nuclear and/or OPG wide suppliers: When OPG becomes aware of a potential supplier interruption a Station Condition Record (SCR) titled “Possible Supplier Interruption: [vendor name]” shall be initiated. Specific actions to address a supplier interruption of any type are then addressed by N-PROC-MM-0010 [N-PROC-MM-0010 R021, OPG Nuclear Procedure, *Establishing and Maintaining Ontario Power Generation Approved Suppliers List*, February 2017]. Among other things, this governance mandates an Approved Supplier List Oversight Committee meeting (ASLOC), which reviews impacts on internal stakeholders and initiates corrective actions as may be required. This governance ensures the risk posed by potential discontinuation of any external supplies or services is effectively mitigated. Furthermore, many of the same external services and supplies required for Pickering are also required for the Darlington station. Darlington is being refurbished to operate far beyond the Pickering extended operating period. OPG’s processes will provide assurance of supply of external services and supplies for the extended life of Darlington and Pickering stations. Accordingly, SF4-1 is adequately addressed by OPG-PROC-0058 [OPG-PROC-0058 R011, OPG Procedure, *Procurement Activities*, March 2017] and N-PROC-MM-0010 [N-PROC-MM-0010 R021, OPG Nuclear Procedure, *Establishing and Maintaining Ontario Power Generation Approved Suppliers List*, February 2017]. As a further enhancement, a Document Change Request has been filed to update N-PROC-MP-0060 on Aging Management to cross reference to the Procurement Activities Procedure OPG-PROC-0058. This work will be managed outside of PSR2. This review has identified that no change is required to N-STD-MA-0024 to address this issue. No further action is required in PSR2. (SF4-1)
GI-15-NFA2	Section 1.4.8.3 of OPG Nuclear Safety Analysis governing document [N-MAN-03600-10005-R006, OPG Manual, *Nuclear Safety Analysis*, September 2016] has been revised to include the use of the best estimate approach or a conservative approach for analysis of operational events. No further action is required. (SF5-7) (SF5-AG3)

B.16. GI-16 Concession Related to N285.5-M90

SECTION 1 - GI-16 GLOBAL ISSUE SUMMARY					
The goal of GI-16, Concession Related to N285.5-M90, is to confirm that concessions granted from CNSC for compliance with CSA N285.5 Periodic Inspection of CANDU Nuclear Power Plant Containment Components remain valid for the extended operating period. This Global Issue comprises two items assessed as requiring No Further Action and one Acceptable Deviation addressing one SF4 code review Gap [CSA N285.5]. GI-16 is Safety Significance Level 4 based on deterministic defence-in-depth considerations. Pickering is currently in compliance with CSA N285.5-08 Update No. 1 [P-CORR-00531-04186]. The approach to situations where components are deemed inaccessible for inspection is addressed in the OPG Periodic Inspection Program (PIP). The PIP Compliance Matrices state that full or partial disassembly of components will not be undertaken specifically for periodic inspection, as this may result in component damage. The CNSC have confirmed their finding that the revised PIPs satisfactorily meet the requirements of CSA N285.5-08 Update No. 1 [P-CORR-00531-04186]. This is not impacted by operation beyond 2020. The proposed Resolution Plan assesses the issue regarding the numerical rules for inspection of identical components as requiring No Further Action because Pickering follows the CSA N285.5-08 requirements. Similarly, the subject requirements of CSA N285.5-M90 for the timing of inspections are assessed as requiring No Further Action because they have been excluded from CSA N285.5-08. The issue regarding the extent of inspections for components deemed inaccessible is assessed as an Acceptable Deviation because of its very low Safety Significance.					
Safety Significance Level:	4	**Category:**	Programmatic	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-16 ASSOCIATED GAPS	
SF4-9	There were a number of concessions granted from the CNSC for compliance with N285.5-M90 that will need to be reconciled for Pickering for the period of PSR2: (Since these Gaps are all concession-related and associated with N285.5-M90, they are tracked under a single PSR2 Gap). a) The Pickering B ISR Gap associated with N285.5-M90 clause 4.5.1 is closed. However, the disposition of the Gap refers to OPG receiving a concession from the CNSC on the inspection of components deemed to be inaccessible. A similar (updated) concession may be required for Pickering operation past 2020. Therefore, this is a Gap for PSR2. b) The Darlington ISR disposition of the Gaps for N285.5-M90 clauses 8.4.2.1 and 8.4.2.2 refer to OPG receiving a concession from the CNSC that insulation will not be removed in the absence of visible damage to a component, and only “light weight” access covers will be removed. The Darlington ISR states: “This is a concession from the regulator which is not assured in the case of refurbished plant.

SECTION 2 - GI-16 ASSOCIATED GAPS

As such, this represents a Gap". By the same logic it will need to be reconciled for Pickering for the period of PSR2 (life extension past 2020).

c) The Darlington ISR disposition of the Gap for N285.5-M90 for clause 8.5.2.2 refers to an exception of the numerical rules of this clause for reasons of practicality, and that a concession was received from the CNSC. The Darlington ISR stated "… it is categorized as a Gap, because a concession from the CNSC is not assured for a refurbished plant." By the same logic it will need to be reconciled for Pickering for the period of PSR2.

d) Per the Darlington ISR disposition of the Gap for N285.5-M90 clause 8.6.3, although CNSC acceptance was obtained, there is still a non-compliance with a portion of the clause related to the timing of inspections which is noted as needing to be reconciled for a refurbished station. The Darlington ISR stated "This represents a Gap that will need to be reconciled with the regulator for a refurbished station." By the same logic it will need to be reconciled for Pickering for the period of PSR2.

Code Review N285.5-13

Associated Resolutions: GI-16-AD1 (Gap Items a and b), GI-16-NFA1 (Gap Item c), GI-16-NFA2 (Gap Item d)

SECTION 3 - GI-16 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains one SF4 Gap related to CNSC concessions on N285.5-M90 [CSA N285.5-M90, *Periodic Inspection of CANDU Nuclear Power Plant Containment Components*], and whether they are affected by Pickering operation beyond 2020. Note: Pickering is currently in compliance with CSA N285.5-08 Update No. 1 [P-CORR-00531-04186].

The issues are related to:

a) CNSC concession on clause 4.5.1 on the inspection of components deemed to be inaccessible.

b) CNSC concession on clauses 8.4.2.1 and 8.4.2.2, that insulation will not be removed in the absence of visible damage to a component, and that only "light weight" access covers will be removed.

c) CNSC concession on clause 8.5.2.2 on the numerical rules of this clause for reasons of practicality.

The requirement in clause 8.5.2.2 of N285.5-08 states that the number of areas to be inspected for identical components in a multi-unit station shall not be fewer than that specified in Table 2 of the standard. Pickering follows the requirements identified in Table 2 of CSA N285.5-08 and the PIPs developed in accordance with CSA N285.5-08 have been accepted by the CNSC [P-CORR-00531-04186]. Therefore, this is no longer a Gap.

d) Clause 8.6.3: The requirements of N285.5-M90 Clause 8.6.3 have been excluded from N285.5-08. Therefore, this is no longer a Gap.

SECTION 4 - GI-16 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	**Overall Safety Significance Level**
	4	N/A	**4**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**4**

Rationale:

Resolution of this Global Issue will confirm applicability of a previously approved concession related to periodic inspection of Containment components.

Regarding deterministic considerations, Defence in Depth (E1) has Safety Significance Level 4 on the basis that no safety function is impacted by the issue. The Safety Significance Level determined from Table E2 in the PSR2 Basis Document is not applicable. The overall significance level for deterministic considerations is 4.

Regarding probabilistic considerations, this Global Issue has no impact on Core Damage Frequency (F1) or Defence in Depth (F2), nor does it impact Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) or the Environment (F7). Therefore probabilistic considerations are not applicable.

In summary, the overall Safety Significance Level is 4.

SECTION 5 - GI-16 RESOLUTION PLAN

GI-16-AD1	SF4-9 Gap Items a and b: CSA N285.5 Clauses 4.5.1, 8.4.2.1 and 8.4.2.2 are related to extent of inspection. The approach to situations where components are deemed inaccessible for inspection is addressed in the following OPG documents: Section 9.2 *Extent and Areas of Inspection* and Appendix F CAN/CSA-N285.5 *Compliance Matrices* of [NK30-PIP-03642.2-00001 R003, OPG Plan, *Pickering Nuclear Generating Station “B” Periodic Inspection Program for Containment Components*, July 31, 2012], [NA44-PIP-03642.2-00001 R002, OPG Plan, *Pickering Nuclear Generating Station “A” Periodic Inspection Program for Containment Components*, July 31, 2012] and Section 9.2 *Extent and Areas of Inspection* and Appendix G CAN/CSA-N285.5-08 *Compliance Matrices* of [P-PIP-03642.2-00001 R003, OPG Plan, *Pickering Nuclear Generating Station Periodic*

SECTION 5 - GI-16 RESOLUTION PLAN	
	Inspection Program for Unit 0 Containment Components, July 31, 2012]. The Compliance Matrices state that full or partial disassembly of components will not be undertaken specifically for periodic inspection, as this may result in component damage. The above PIPs have been accepted by the CNSC. In [NK30-CORR-00531-04876, CNSC Correspondence, e-Doc 3256609/ 2.01, *Pickering NGS-B Integrated Safety Review (ISR) - CNSC Review of Acceptable Deviations and Discrepancies for the Plant Design Safety Factor Report,* June 27, 2008], it is stated that the CNSC has accepted the reasonableness of the proposed solution to the above discrepancy and in [P-CORR-00531-04186, *Transition to 2008 Edition of CSA N285.5 Update No. 1 – Periodic Inspection of CANDU Nuclear Power Plant Containment Components – Submission of Periodic Inspection Programs,* November 2012], the CNSC confirmed their finding that the revised PIPs satisfactorily meet the requirements of CSA N285.5-08 Update No. 1. This is not impacted by operation beyond 2020. Appendix E of the Periodic Inspection Plans for Pickering B, e.g., [NK30-PIP-03641.2-00001, *Pickering Nuclear Generating Station B Periodic Inspection Plan for Unit 5*, August 2006] and Section 4 of the Periodic Inspection Plans for Pickering A, e.g., [NA44-PIP-03641.2-00001, *Pickering Nuclear Generating Station A Periodic Inspection Plan for Unit 1*, September 2006], state that "*Where the inspection of a system or component would necessitate the dismantling of equipment, the required inspection should be performed when the equipment is dismantled for other reasons (i.e., maintenance)*". As per the very low safety significance (Safety Significance Level 4), this is assessed as an Acceptable Deviation. (SF4-9, Items a and b)
GI-16-NFA1	The Pickering PIPs, accepted by the CNSC [P-CORR-00531-04186], are consistent with the requirements identified in Clause 8.5.2.2 and Table 2 of CSA N285.5-08, which relate to the number of areas to be inspected for identical components in a multi-unit station. No action is required. (SF4-9, Item c)
GI-16-NFA2	Clause 8.6.3 of the M90 edition of CSA N285.5 has been excluded from the 2008 edition of the standard. Pickering Containment PIPs have been accepted by the CNSC and the CNSC confirmed their finding that the PIPs satisfactorily meet the requirements of CSA N285.5-08 Update No. 1 [P-CORR-00531-04186, *Transition to 2008 Edition of CSA N285.5 Update No. 1 – Periodic Inspection of CANDU Nuclear Power Plant Containment Components – Submission of Periodic Inspection Programs,* November 14, 2012]. No action is required. (SF4-9, Item d)

B.17. GI-17 FFS of Fiberglass Reinforced Plastic Material for the Extended Operating Period

SECTION 1 - GI-17 GLOBAL ISSUE SUMMARY					
The goal of GI-17, FFS of Fiberglass Reinforced Plastic Material for the Extended Operating Period, is to confirm that the Fiberglass Reinforced Plastic (FRP) components remain fit for service for the extended operating period. This Global Issue comprises one item assessed as requiring No Further Action addressing one SF4 code review Gap [CSA N285.5-13]. GI-17 is Safety Significance Level 2 based on deterministic and probabilistic defence-in-depth considerations as well as plant operability considerations. The changes in N285.5-13 relative to N285.5-08 that are applicable to FRP material that is used at Pickering NGS have been assessed for fitness for service to 2024 [NA44-PLAN-34220-00002 R001, *Life Cycle and Aging Management Program Plan for Fiberglass-Reinforced Plastic Components in the Pickering NGS Vacuum Building*, September 27, 2012]. The proposed Resolution Plan assesses this issue as requiring No Further Action because the adequacy of the FRP material used at Pickering NGS has been assessed for fitness for service to 2024.					
Safety Significance Level:	2	**Category:**	Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-17 ASSOCIATED GAPS	
SF4-10	The changes in N285.5-13 relative to N285.5-08 that are applicable to Fiberglass Reinforced Plastic material that is used at Pickering NGS have only been assessed for fitness for service to 2024 in the Pickering Continued Operations Plan. These changes related to aging management (monitoring and test programs) for FRP materials. As a result, additional assessment is required for Pickering to address FRP aging management at Pickering for operation to 2028[33], and to confirm the current program aligns with N285.5-13 clauses 8.2, 8.3.3, 8.3.4 and A.6.1.2 (Note: This Gap only exists if Pickering NGS intends to operate past 2024). ***Code Review N285.5-13*** **Associated Resolutions:** GI-17-NFA1

SECTION 3 - GI-17 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains one SF4 gap related to FFS of Fiberglass Reinforced Plastic (FRP). The changes in N285.5-13 relative to N285.5-08 that are applicable to FRP material that is used at Pickering NGS have been assessed for fitness for service to 2024 [NA44-PLAN-34220-00002 R001, *Life Cycle and Aging Management Program Plan for Fiberglass-Reinforced Plastic Components in the*

SECTION 3 - GI-17 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

Pickering NGS Vacuum Building, October 2012], [P-CALC-34000-00006 R000, *Material Properties for FRP Components Used in Pickering Vacuum Building Based on 2015 Test Results*, March 2017].

SECTION 4 - GI-17 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	2	N/A	**2**	4	2	4	2	N/A	N/A	N/A	**2**	**2**

Rationale:

Addressing this Global Issue will ensure the fitness for service of Fiberglass-Reinforced Plastic Components in the Pickering NGS Vacuum Building for the operational life of the station. As discussed in Section 3 of this Global Issue, the fitness for service of these components is currently assured to 2024.

This Global Issue is assigned Safety Significance Level 2 for deterministic considerations with respect to Defence in Depth (E1) since ensuring ongoing fitness for service will avoid a reduction in margin of safety to public or station personnel. This is consistent with the definition of Safety Significance Level 2 in Table E1 in the PSR2 Basis Document. Safety Significance Levels (E2) is considered not applicable because this Global Issue can have an impact on nuclear safety, whereas E2 primarily relates to issues without a direct impact on nuclear safety. Hence, the overall Safety Significance Level is 2 for deterministic considerations.

With respect to probabilistic considerations, this Global Issue is conservatively assigned Safety Significance Level 2 with respect to Table F2 in the PSR2 Basis Document, since resolution of this issue will exclude a possible reduction in the reliability of System Important to Safety for any probable relevant event (third row of Table F2 in the PSR2 Basis Document). Similarly, the Safety Significance Level with respect to Plant Operability (F4) is also 2, since an extended period of plant shutdown as a result of fitness for service issues is expected to have a probability less than 0.1.

Safety Significance Level 4 is assigned to Reactor Safety - Core Damage Frequency (F1) and Public Radiation Safety (F3) since this Global Issue will have an insignificant impact on these probabilistic considerations.

This Global Issue has no impact on the other probabilistic considerations, i.e., Occupational Radiation

SECTION 4 - GI-17 PRIORITY DETERMINATION
Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these probabilistic considerations are not applicable. In summary, both deterministic and probabilistic considerations dictate that this Global Issue has Safety Significance Level 2. As noted, the fitness for service of these components has been demonstrated to 2024.

SECTION 5 - GI-17 RESOLUTION PLAN	
GI-17-NFA1	The adequacy of the FRP material used at Pickering NGS has been assessed for fitness for service to 2024. (SF4-10)

B.18. GI-18 N287.7 - In-Service Examination and Testing Requirements for Concrete Containment Structures

SECTION 1 - GI-18 GLOBAL ISSUE SUMMARY					
The goal of GI-18, N287.7 – In-Service Examination and Testing Requirements for Concrete Containment Structures, is to confirm that the requirements of CSA N287.7 are satisfied for the extended operating period. This Global Issue comprises one item assessed as requiring No Further Action and one Acceptable Deviation, addressing two SF4 code review Gaps [CSA N287.7]. GI-18 is Safety Significance Level 4 based on deterministic defence-in-depth considerations. This Global Issue addresses two specific issues related to CSA N287.7. The first relates to the accuracy and repeatability capability of standard available commercial sensors in testing equipment. OPG will continue to request concessions pending resolution of this issue through the CSA committee that is working to update CSA N287.7 with respect to this issue. The second issue relates to compliance with the standard for a sealant used in repairs. OPG has addressed this issue and the related Action Item 2013-8-4515 has been closed by the CNSC [P-CORR-00531-04787]. The proposed Resolution Plan assesses the issue regarding the accuracy and repeatability requirements in testing equipment as an Acceptable Deviation because of its very low Safety Significance. The issue regarding the Dow Corning sealant is assessed as requiring No Further Action because it has been addressed to the satisfaction of the CNSC.					
Safety Significance Level:	4	**Category:**	Analytical, Programmatic	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-18 ASSOCIATED GAPS	
SF4-11	N287.7-08 clause 7.11.2 Table 1 involving non-compliance with accuracy and repeatability requirements for dew point temperature was a Gap for Darlington. No evidence can be found that this has been addressed for Pickering NGS. This is therefore a Gap for Pickering PSR2. ***Code Review N287.7-08*** **Associated Resolutions:** GI-18-AD1
SF4-12	OPG initiated a Regulatory Management action to provide the CNSC with the latest Dow Corning 995 material test report in response to an Action Notice raised in the CNSC Type II Inspection. The work is currently in progress. Therefore, this is a Gap for Pickering PSR2. ***Code Review N287.7-08*** • **Note – Per GI-18-NFA1, this Gap has been fully addressed.** **Associated Resolutions:** GI-18-NFA1

SECTION 3 - GI-18 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains two SF4 Gaps related to in-service examination and testing requirements for Concrete Containment Structures.

The Gap SF4-11 is related to N287.7-08 clause 7.11.2 on the accuracy requirement for dew point temperature measurement and repeatability requirement for pressure transmitter measurements for leakage rate testing. Current instrumentation data does not meet the accuracy requirement for dew point temperature of ± 1°C and for pressure transmitter measurement repeatability requirement of ± 0.001% of full scale. Currently industry can meet ± 2°C for dew point temperature accuracy, and ± 0.05% full scale for pressure transmitter measurement repeatability.

As per Action Notice 3 (AN3) of CNSC Action Item 2013-8-4515, OPG committed to develop and implement corrective actions to address the repairs that were performed with the Dow Corning sealant in order to become compliant with sub-section 6.6.1 of the Periodic Inspection Program for the Reactor Building [NK30-PIP-03643.2-00001-R003, OPG Plan, *Pickering Nuclear GSB – Reactor Building Periodic Inspection Program*, February 2014]. Based on OPG's AN3 update and request for closure [NK30-CORR-00531-07245, OPG Correspondence, *CNSC Action Item 2013-8-4515, AN3 Update and Request for Closure – Pickering Units 5 to 8: CNSC Type II Compliance Inspection Report, # PRPD-2013-182*, June 29, 2016], CNSC staff confirmed that OPG meets the closure criteria for (AN3) and has closed the Action Item 2013-8-4515 [P-CORR-00531-04787, CNSC Correspondence, e-Doc 5034577, *Pickering NGS: Closure of CNSC Action Item 2013-8-4515, Type II Compliance Inspection – Implementation of CSA N285.4, N285.5 and N287.7*, July 7, 2016].

SECTION 4 - GI-18 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	4	N/A	**4**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**4**

Rationale:

This Global Issue is related to in-service examination and testing for Concrete Containment Structures.

Regarding deterministic considerations, this Global Issue has Safety Significance Level 4 with respect

SECTION 4 - GI-18 PRIORITY DETERMINATION
to Defence in Depth (E1). This is because, as discussed in Section 3 of this Global Issue, the gap is against a requirement for accuracy and repeatability of measurements that cannot be met. CNSC has accepted applicable concessions for the issue, and the CSA committee is working to update CSA N287.7. E2 Safety Significance Levels is considered not applicable. Therefore, Safety Significance Level 4 is selected for deterministic considerations. This Global Issue has no direct impact on probabilistic considerations, i.e., Core Damage Frequency (F1), Defence in Depth (F2), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) or Environment (F7). Therefore, probabilistic considerations are not applicable. In summary, the overall Safety Significance Level is 4.

SECTION 5 - GI-18 RESOLUTION PLAN	
GI-18-AD1	A CSA committee is working to update CSA N287.7 to account for accuracy and repeatability capability of standard available commercial sensors in testing equipment. OPG is actively participating on this committee. Until such time as N287.7 is revised, OPG will continue to request appropriate concessions from the CNSC when leak rate testing is required. Examples of concession approvals are [NK30-CORR-00531-07225, *Pickering NGS: Concession Request for Instrumentation Related to Unit 8 Containment Leak Rate Testing*, e-Doc 4970098, April 2016] and [NA44-CORR-00531-07599, *Pickering NGS: Concession Request for Instrumentation Related to Unit 4 Containment Leak Rate Testing*, e-Doc 4937932, February 2016]. As per the very low safety significance (Safety Significance Level 4), this is assessed as an Acceptable Deviation. (SF4-11).
GI-18-NFA1	The Action Notice (AN3) of Action Item 2013-8-4515 has been addressed to the satisfaction of the CNSC [P-CORR-00531-04787, CNSC Correspondence e-Doc 5034577, *Pickering NGS: Closure of CNSC Action Item 2013-8-4515, Type II Compliance Inspection – Implementation of CSA N285.4, N285.5 and N287.7*, July 7, 2016]. No further action is required. (SF4-12)

B.19. GI-19 FFS of Containment for the Extended Operating Period

SECTION 1 - GI-19 GLOBAL ISSUE SUMMARY					
The goal of GI-19, FFS of Containment for the Extended Operating Period, is to ensure that the safety-significant civil structures of Containment remain fit for service for the extended operating period. This Global Issue comprises one proposed Resolution Statement and one item assessed as requiring No Further Action, addressing 3 Gaps: one SF4 code review Gap [CSA N287.7-08], and two COP Review Gaps. GI-19 is Safety Significance Level 2 based on deterministic and probabilistic defence-in-depth considerations. Containment building structures are covered by Administrative Requirements for In Service Inspection and Testing for Concrete Containment Structures [N-PROC-MA-0066 R005]. The Periodic Inspection Programs (PIPs) cover the Vacuum Building and the Pressure Relief Duct, the Vacuum Building Post Tensioning Rods and the Reactor Buildings. The final report for the PIP inspection program incorporates all results, and any repairs and recommendations, arising from the PIP inspections to ensure fitness for service of the Reactor Buildings, Pressure Relief Duct and Vacuum Building structures. OPG's path forward with regard to demonstrating whether the foundation steel H-piles at the Pickering site will withstand their design loads for all civil structures that they support for operation beyond 2020 was communicated to the CNSC [P-CORR-00531-04896]. The proposed Resolution Plan comprises activities to demonstrate the FFS of the foundation steel H-piles at the Pickering site for the extended operating period. The remaining issues are assessed as requiring No Further Action because the Containment PIPs are in place to cover the extended operating period. Completion of the proposed Resolution Plan will support and strengthen Level 1 defence-in-depth for the extended operating period.					
Safety Significance Level:	2	**Category:**	Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-19 ASSOCIATED GAPS	
SF4-13	Actions #31, #32, and #33 from the Pickering Units 5-8 Continued Operations Plan are related to N287.7 and although complete, need to be reassessed for Pickering operation past 2020. (COP Action #31 involved submission of Periodic Inspection Plans and Life Cycle Management Plans for a number of safety-significant civil structures. COP Action #32 involved submission of Aging Management Plans for Concrete Containment Structures to the CNSC for acceptance. COP Action #33 involved revising the Reactor Building Periodic Inspection Plan and submitting to the CNSC for acceptance.) ***Code Review N287.7-08*** Note: Actions #32 and #33 are covered under this Global Issue. **Associated Resolutions:** GI-19-NFA1

SECTION 2 - GI-19 ASSOCIATED GAPS	
COP-16	Reassessment of the Vacuum Building Outage schedule and basis for maintaining a fully serviceable Containment boundary has not been completed for extended operation and until Negative Pressure Containment can be demonstrated to no longer be required. ***Pickering PSR2 Gap COP-16*** • **Note – Per GI-19-NFA1, this Gap has been fully addressed.** **Associated Resolutions:** GI-19-NFA1
COP-25	An assessment of margin to operate all the Pickering Reactor Building foundations has not been completed for the period of extended operation and until Reactor Building integrity can be demonstrated to no longer be required. This issue applies also to the Vacuum Building and Pressure Relief Duct for the extended operation period and for the period until the Negative Pressure Containment System integrity can be demonstrated to no longer be required. ***Pickering PSR2 Gap COP-25*** **Associated Resolutions:** GI-19-RS1

SECTION 3 - GI-19 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains three Gaps (one SF4 Gap and two COP Review Gaps) that are related to fitness for service of Containment.

Non-Containment safety-related civil structures are covered in GI-43.

SF4-13 includes three actions (#31, #32, and #33) from the Pickering Units 5-8 COP [NK30-PLAN-00531-00001 R005, OPG Plan, *Pickering 5-8 Continued Operations Plan*, November 2015]. Action #31 states “Include the periodic inspection programs and LCMPs for the safety-significant civil structures that are under the scope of CSA N291-08, but not covered by the N287.7 standard”. This applies to non-Containment structures and accordingly is not dealt with in this Global Issue but is considered in GI-43. Action #32 involved submission of Aging Management Plans for Concrete Containment Structures to the CNSC for acceptance. Action #33 involved revising the Reactor Building Periodic Inspection Plan and submitting to the CNSC for acceptance. Accordingly, both Actions #32 and #33 pertain to issues that are within the scope of this Global Issue (GI-19).

Containment building structures are covered by Periodic Inspection Programs per [N-PROC-MA-0066 R005, OPG Nuclear Procedure, *Administrative Requirements for In Service Inspection and Testing for Concrete Containment Structure*, April 24, 2014].

NA44-PIP-03643.2-00002-R002 [NA44-PIP-03643.2-00002 R002, OPG Plan, *Pickering Nuclear GS – PRD & VB Periodic Inspection Program*, February 4, 2014] covers the Vacuum Building and the Pressure Relief Duct, NA44-PIP-03643.2-00003-R002 [NA44-PIP-03643.2-00003 R002, OPG Plan, *Pickering Nuclear GS – Vacuum Building Post Tensioning Rods Periodic Inspection Program*, April 30, 2014] is the PIP program for the Vacuum Building post tensioning rods, and the Periodic Inspection

SECTION 3 - GI-19 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

Plans for the Reactor Buildings are:

- [NA44-PIP-03643.2-00001 R003, *Pickering Nuclear GSA – Reactor Building Periodic Inspection Program*, February 2014]
- [NK30-PIP-03643.2-00001 R003, *Pickering Nuclear GSB – Reactor Building Periodic Inspection Program*, February 2014]

The in-service leakage rate test requirements of the Reactor Buildings and Pressure Relief Duct, in accordance with CSA N287.7, are specified in NA44-REP-34200-00017 [NA44-REP-34200-00017 R000, OPG Report, *Pickering NGS "A" Reactor Building and Pressure Relief Duct In-Service Leakage Rate Test Requirements in Accordance with CSA N287.7-08*, September 20, 2011], while those for the Vacuum Building are specified in NA44-REP-25100-00009-R000 [NA44-REP-25100-00009 R000, OPG Report, *Pickering NGS Vacuum Building In-Service Leakage Rate Test Requirements in Accordance with CSA N287.7-08*, November 2, 2012]. Leakage rate testing of the Reactor Buildings, the Pressure Relief Duct and the Vacuum Building is conducted on a schedule approved by the CNSC. The final report for the PIP inspection program incorporates all results, and any repairs and recommendations, arising from the PIP inspections to ensure fitness for service of the Reactor Buildings, Pressure Relief Duct and Vacuum Building structures.

SECTION 4 - GI-19 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	2	N/A	**2**	N/A	2	4	4	N/A	N/A	N/A	**2**	**2**

Rationale:

Resolution of this Global Issue will confirm the fitness for service of Containment for the operational life of the station.

Regarding deterministic considerations, Defence in Depth (E1) is assigned Safety Significance Level 2 since assuring fitness for service confirms the effectiveness of the Containment barrier (column 1, second row of Table E1 in the PSR2 Basis Document). Safety Significance Levels (E2) is assessed as not applicable because this Global Issue can have a direct nuclear safety impact, whereas E2 primarily relates to issues without a direct impact on nuclear safety. The overall Safety Significance Level for

SECTION 4 - GI-19 PRIORITY DETERMINATION

deterministic considerations is 2.

Regarding probabilistic considerations, Defence in Depth (F2) is assigned Safety Significance Level 2 since resolving this Global Issue precludes a challenge to the safety barrier (Containment) for events with initiating frequency less than 10^{-3}/y.

Safety Significance Level 4 is assigned for Public Radiation Safety (F3) on the basis that ensuring fitness for service of Containment precludes a potential change in public dose of less than 1 mSv for events with initiating frequency > 10^{-5}/y (row 4, column 4 in Table F3 in the PSR2 Basis Document). This Global Issue has insignificant impact on Plant Operability (F4), i.e., ~ 0.001 probability that the issue requires or leads to an extended period of plant shutdown. This Global Issue has no direct impact on the other probabilistic considerations, i.e., Core Damage Frequency (F1), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these probabilistic considerations are not applicable.

In summary, the overall Safety Significance Level is 2. Containment Periodic Inspection Plans are in place to cover the extended operating period, and work is under way to demonstrate the fitness for service of the foundation steel H-piles at the Pickering site for the extended operating period.

SECTION 5 - GI-19 RESOLUTION PLAN

GI-19-RS1	Demonstrate the FFS of the foundation steel H-piles for the Pickering A Reactor Building, Vacuum Building, and Pressure Relief Duct at the Pickering site for the extended operating period, as specified in [P-CORR-00531-04896, *Pickering NGS: Continued Operations Plan (COP) Actions F06 and I15-6B - Periodic Safety Review Reassessment for Operation Beyond 2020*, January 23, 2017] and in [P-CORR-00531-04973, *Pickering NGS: CNSC Staff Review of OPG's Reassessment of COP Actions for Consideration in the PSR2*, February 24, 2017]. (COP-25) This Resolution Statement also includes/addresses GI-43.
GI-19-NFA1	Containment PIPs were updated to comply with CSA N287.7-08, submitted to the CNSC for approval, and subsequently accepted by the CNSC in [P-CORR-00531-04265, *Pickering NGS: Acceptance of CSA N287.7-08 Periodic Inspection Program Documents, Action Item 2010-8-10 (RIB 2471), 2010-8-03 (RIB 2458), and 2010-4-18 (RIB 2478)*, June 2014]. The current PIPs include inspections required to be performed during a Vacuum Building Outage. The current Pickering planning basis is to perform the Vacuum Building Outage in 2020. There is no further PSR2 action required. (SF4-13 Actions #32 and #33) (COP-16)

B.20. GI-20 Governance Implementation / Effectiveness Issues

SECTION 1 - GI-20 GLOBAL ISSUE SUMMARY					
The goal of GI-20, Governance Implementation / Effectiveness Issues, is to ensure that Pickering Governance is effectively implemented for the extended operating period. This Global Issue comprises two Acceptable Deviations and one Cross Reference to GI-8 addressing two SF4 code review Gaps [REGDOC-2.6.3] and one SF4 Gap from Audits and Self-Assessment Reviews. GI-20 is Safety Significance Level 4 based on deterministic safety significance levels considerations. A plan to ensure the implementation of OPG's Aging Management Process, N-PROC-MP-0060, requirements for reviewing and updating the Condition Assessments, has been developed and provided to CNSC staff [P-CORR-00531-04805]. Completion of the actions addressing oversight and implementation of the Integrated Aging Management Program (IAMP) is being actively addressed outside of PSR2. The issue related to ensuring qualified individuals perform Aging Management engineering activities is closed and corrective actions are complete. The proposed Resolution Plan assesses the implementation of N-PROC-MP-0060 requirements and oversight and implementation of the IAMP as Acceptable Deviations because of their very low Safety Significance and because they are being addressed outside of PSR2. Completion of the Condition Assessments consistent with the revised Reactor Safety Criticality Codes is Cross Referenced to GI-8, Completion / Updating of the Condition Assessments.					
Safety Significance Level:	4	**Category:**	Programmatic, Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-20 ASSOCIATED GAPS	
SF4-14	OPG is not compliant with N-PROC-MP-0060 Aging Management Process, Section 1.7 for "not reviewing and updating the Component Condition Assessments within the review cycle of the component, and when new information or feedback from the program was received." OPG has since revised these CAs, which are now valid until 2020. OPG has stated they will develop an implementation plan to prevent reoccurrence of: a) not reviewing and revising the CAs within the review cycle, and b) not updating the CAs when pertinent new information becomes available. OPG stated they will provide an update and a target implementation date on this action to the CNSC by October 30, 2016. This is a Gap for Pickering PSR2. ***Code Review CNSC REGDOC-2.6.3*** **Associated Resolutions:** GI-20-AD1
SF4-15	OPG is not compliant with N-PROC-MA-0077, *Critical Equipment Identification and Categorization*, Section 1.2 because "the Reactor Safety (RS) category code and rationale for critical components was not always accurate or consistently applied in the CCAs." OPG has stated they have since completed a review and update of the RS category code and rationale for a portion of the components to become fully compliant with N-PROC-MA-0077. However, OPG has stated that a review of the CAs will be conducted to ensure consistency

SECTION 2 - GI-20 ASSOCIATED GAPS	
	with the revised Reactor Safety codes and that an update will be provided to the CNSC by October 30, 2016. This is a Gap for Pickering PSR2. ***Code Review CNSC REGDOC-2.6.3*** **Associated Resolutions:** GI-8-RS1
SF4-17	Per Section B.1, Nuclear Oversight conducted a performance based audit (NO-2016-027) of the IAM Program in March 2016. The purpose of the audit was to determine whether IAM program requirements are being met and are effectively implemented to support safe and reliable operation. The audit concluded that the managed system controls are not fully effective and identified the following two open findings applicable to Pickering NGS which result in a PSR2 Gap (Note: These Gaps are closely related and are therefore identified as a single PSR2 Gap): • The IAM program requires that the interfacing programs affecting critical component condition should be comprehensive and sufficiently integrated to ensure critical information and assumptions used in completing Condition Assessments and Aging Management activities are valid and effective. However, a lack of integrated life cycle initiatives has been identified, which has the potential to impact equipment health. In addition, the program defines the requirements for program oversight and implementation. However, issues were identified in the completion of Condition Assessments and the execution of related recommendations due to ineffective oversight and implementation of the IAM program. SCR N-2016-08041 (AR#28189056) has been raised to address this issue and is expected to be completed by Q4 2017. This is a Gap for PSR2 since the SCR is not yet closed, and missing information in Condition Assessments and incomplete actions may lead to ineffective management of the aging equipment and impact the reliability of SSCs. • The IAM implementing procedure identifies the requirement for qualified individuals to perform Aging Management engineering activities such as preparing and reviewing Condition Assessments and screening reports. The audit identified that some Engineering Support Personnel performed engineering work independently while they were not qualified in the Training Information Management System. SCR P-2016-08008 (AR#28189028) has been raised to address this issue and is expected to be completed by Q3 2016. This is a Gap for PSR2 since the SCR is not yet closed, and unqualified staff performing work independently could impact the quality of Engineering work including Aging Management work activities. ***Audit and Self-Assessment Reviews*** **Associated Resolutions:** GI-20-AD2

SECTION 3 - GI-20 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue consolidates a total of three SF4 Gaps related to effective implementation of OPG governance.

SECTION 4 - GI-20 PRIORITY DETERMINATION												
Safety Significance of Global Issue	**Deterministic Considerations**			**Probabilistic Considerations**								**Overall Safety Significance Level**
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	N/A	4	**4**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**4**

Rationale:

This Global Issue includes minor issues related to the implementation or effectiveness of OPG governance.

Regarding deterministic considerations, Defence in Depth (E1) is not applicable since this Global Issue is not associated with a physical barrier. Safety Significance Levels (E2) is assigned Safety Significance Level 4 since resolution of this issue “may help identify areas that need more attention”, in this case the adequacy of governance implementation or its effectiveness. Therefore, Safety Significance Level 4 is selected for deterministic considerations.

This Global Issue has no direct impact on the probabilistic considerations, i.e., Core Damage Frequency (F1), Defence in Depth (F2), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, probabilistic considerations are not applicable.

In summary, the overall Safety Significance Level is 4. OPG is addressing this issue outside of PSR2.

SECTION 5 - GI-20 RESOLUTION PLAN	
GI-20-AD1	An implementation plan to ensure the implementation of N-PROC-MP-0060 requirements [N-PROC-MP-0060 R005B, OPG Nuclear Procedure, *Aging Management Process,* October 1, 2015] for reviewing and updating the Condition Assessments within the review cycle of the component, and when new information or feedback from the program is received, has been developed and provided to CNSC staff [P-CORR-00531-04805, OPG Correspondence, *CNSC Action Item 2015-48-7043, Action Notice AN1 and AN2 Update – Type II Compliance Inspection Report, Integrated Aging Management Program #PRPD- 2015-015*, October 28, 2016]. OPG is actively progressing the implementation plan activities outside of PSR2. As per the very low safety significance (Safety Significance

SECTION 5 - GI-20 RESOLUTION PLAN	
	Level 4), this is assessed as an Acceptable Deviation. (SF4-14)
GI-20-AD2	AR # 28189028 is closed and corrective actions are complete. Completion of the actions in AR # 28189056 addressing oversight and implementation of the IAM program is being actively addressed outside of PSR2. As per the very low safety significance (Safety Significance Level 4), this is assessed as an Acceptable Deviation. (SF4-17)
GI-20-XRF-GI-8-RS1	The Condition Assessments being completed are consistent with the revised Reactor Safety Criticality Codes. Complete the Condition Assessments. (SF4-15)

B.21. GI-21 FFS of the Deaerator and the Deaerator Storage Tank for the Extended Operating Period

SECTION 1 - GI-21 GLOBAL ISSUE SUMMARY					
The goal of GI-21, FFS of the Deaerator and the Deaerator Storage Tank for the Extended Operating Period, is to ensure that the Deaerator and the Deaerator Storage Tank remain fit for service for the extended operating period. This Global Issue comprises one Cross Reference to GI-8 addressing one COP Review Gap. GI-21 is Safety Significance Level 3 based on deterministic and probabilistic defence-in-depth considerations. The COP Review Gap action to respond to a CNSC inquiry regarding this issue has been completed, and is documented in the *Pickering 5-8 Continued Operations Plan* [NK30-PLAN-00531-00001-R004]. Fitness for service of the Deaerator and Deaerator Storage Tanks at Pickering NGS for the extended operating period is addressed in GI-8. Therefore, in the proposed Resolution Plan, completion of the Condition Assessment of the Deaerator and the Deaerator Storage Tank is Cross Referenced to GI-8, Completion / Updating of the Condition Assessments. Completion of the proposed Resolution Plan will support and strengthen Level 1 defence-in-depth for the extended operating period.					
Safety Significance Level:	3	**Category:**	Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-21 ASSOCIATED GAPS	
COP-23	A review for the full period of extended operation has not been performed to confirm that corrosion fatigue will not affect the welds in the deaerator and the deaerator storage tank for Pickering Units 1,4 and 5-8. ***Pickering PSR2 Gap COP-23*** **Associated Resolutions:** GI-8-RS1

SECTION 3 - GI-21 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains one COP Review Gap related to FFS of the Deaerator and Deaerator Storage Tank. This COP Review Gap action was to provide a response to a specific CNSC inquiry. This action was completed. The issue is documented, with references, under Item #69 of Appendix A in [NK30-PLAN-00531-00001-R004, *Pickering 5-8 Continued Operations Plan*, December 2014]. This issue has not been assessed in the context of extended operation and for Pickering Units 1,4. Fitness for service of the Deaerator and Deaerator Storage Tanks at Pickering NGS for the extended operating period is addressed in GI-8.

SECTION 4 - GI-21 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	3	N/A	**3**	4	3	N/A	4	N/A	N/A	N/A	**3**	**3**

Rationale:

Resolution of this Global Issue will ensure fitness for service of the Deaerator and Deaerator Storage Tank for the extended operating period.

Regarding deterministic considerations, Defence in Depth (E1) is assigned Safety Significance Level 3 on the basis that the issue does not adversely impact the capability of safety provisions to terminate an anticipated process failure, and that resolving the issue will ensure the specific safety function of providing feed water from the Deaerator. Safety Significance Levels (E2) is assessed as not applicable because this Global Issue can have a direct nuclear safety impact, whereas E2 primarily relates to issues without a direct nuclear safety impact. The overall Safety Significance Level for deterministic considerations is 3.

Regarding probabilistic considerations, Defence in Depth (F2) is similarly assigned Safety Significance Level 3 on the basis that resolving the issue precludes a partial loss of safety margin for events with initiating frequency less than 10^{-3}/y.

This Global Issue has insignificant impact on Reactor Safety – Core Damage Frequency (F1) and Plant Operability (F4), and therefore Safety Significance Level 4 is assigned for these considerations. This Global Issue has no direct impact on Public Radiation Safety (F3), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7), and therefore these considerations are not applicable.

In summary, the overall Safety Significance Level is 3. OPG has activities underway to address this Global Issue.

SECTION 5 - GI-21 RESOLUTION PLAN

GI-21-XRF-GI-8-	Complete the Condition Assessments for the Deaerator and Deaerator Storage

SECTION 5 - GI-21 RESOLUTION PLAN

B.22. GI-22 COP Actions Related to Aging Management from SFR4

SECTION 1 - GI-22 GLOBAL ISSUE SUMMARY					
The goal of GI-22, COP Actions Related to Aging Management, is to ensure that a group of 13 Pickering Units 5-8 COP actions related to aging management and one SF2 Additional Gap are addressed in PSR2. A number of these issues are also applicable to Pickering Units 1,4. This Global Issue comprises two Cross References to GI-1, one Cross Reference to GI-2, one Cross Reference to GI-3, two Cross References to GI-4, one Cross Reference to GI-8, one Cross Reference to GI-24, and one Cross Reference to GI-43, addressing one SF4 Gap and one SF2 Additional Gap. As the issues relate to demonstration of fitness for service of SSCs for the extended operating period, GI-22 is assigned Safety Significance Level 2. All of the proposed Resolution Statements for this Global Issue are cross-references to proposed Resolution Statements for other Global Issues (GI-1, GI-2, GI-3, GI-4, GI-8, GI-24 and GI-43). Completing the activities identified in the cross referenced proposed Resolution Statements will effectively address the COP actions and SF2 Additional Gap identified in this Global Issue. Completion of the cross referenced proposed Resolution Statements of GI-1, GI-2, GI-3, GI-4, GI-8 and GI-43 will support and strengthen Level 1 defence-in-depth for the extended operating period while those cross referencing GI-24 will support and strengthen Levels 2 and 3 defence-in-depth for the extended operating period.					
Safety Significance Level:	2	**Category:**	Programmatic, Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-22 ASSOCIATED GAPS	
SF4-18	Review of the Pickering Units 5-8 Continued Operations Plan [OPG Plan, NK30-PLAN-00531-00001 R005, *Pickering 5-8 Continued Operations Plan*, November 2015] identified the following closed gaps from the Pickering B ISR that will need to be revisited in the context of continued operation past 2020 for PSR2 Safety Factor 4. Appendix A Item 4 Demonstrate adequate safety margins to operate Pickering B units from a Heat Transport System aging perspective to Jan 31, 2021. The 2015 strategy update to CNSC staff provided a progress report on Heat Transport System (HTS) Aging Safety Analysis and related activities, and an updated revision of the HTS Aging Management Strategy for the period 2015-2020. This needs to be expanded to cover operation past 2020 for Pickering Units 1,4 and Units 5-8. Therefore, this is a gap for Pickering PSR2. Appendix A Items 10, 11, 12, 13 Develop a strategy to provide evidence that the Calandria Tube (CT) - Liquid Injection Shutdown System (LISS) nozzle gap will be maintained beyond 240,000 Effective Full Power Hours (EFPH) for all Pickering B units.

SECTION 2 - GI-22 ASSOCIATED GAPS	
	The strategy for CT - LISS nozzle gap preservation may apply beyond 2025, but this needs to be confirmed. Therefore, this is a gap for Pickering PSR2. <u>Appendix A Item 14</u> Develop R&D justification for extending Fuel Channel design life beyond 240,000 EFPH in the areas of hydrogen ingress, fracture toughness, spacer mobility and integrity. Actions were constrained by the shutdown date of 2020 assumed in the 2011 business plan. This needs to be expanded to cover operation past 2020 and is therefore a gap for Pickering PSR2. Note: An interim LCMP update for Major Components is documented in [P-CORR-01060-0587604 R000, OPG Memorandum, *Fitness for Service of Major Components*, March 29, 2016], which describes life cycle management strategies for Major Components to achieve extended operation to 2024. Strategies in this document may apply beyond 2024, but this needs to be confirmed as part of the resolution of this COP related PSR2 gap. <u>Appendix A Item 19</u> Update the NOP analysis for Pickering B. Actions were constrained by the shutdown date of 2020 assumed in the 2011 business plan. This is primarily relevant to Safety Factor 5 but is also of relevance to Safety Factor 4. This needs to be expanded to cover operation past 2020 for Pickering Units 1,4 and Units 5-8. Therefore, this is a gap for Pickering PSR2. <u>Appendix A Item 21</u> With respect to the Feeder LCMPs, clarify the impact of Fuel Channel axial elongation during operation beyond the Fuel Channel assumed design life of 210,000 EFPH on Feeder stress analysis and acceptable Feeder thickness. This was only addressed to 2025. This needs to be expanded to cover operation to 2028[33]. Therefore, this is a gap for Pickering PSR2. Note: An interim LCMP update for Major Components is documented in [P-CORR-01060-0587604 R000 OPG Memorandum, *Fitness for Service of Major Components*, March 29, 2016], which describes life cycle management strategies for Major Components to achieve extended operation to 2024. Strategies in this document may apply beyond 2024, but this needs to be confirmed as part of the resolution of this COP related PSR2 gap. <u>Appendix A Item 30</u> Include the Periodic Inspection Programs and LCMPs for the secondary side pressure retaining components and submit them for CNSC review. Although the action to submit PIPs and LCMPs for the secondary side pressure retaining components is complete, these documents will need to be extended to cover operation past 2020 for Pickering Units 1,4 and Units 5-8. Therefore, this is a gap for Pickering PSR2. <u>Appendix A Item 52</u> Perform Time Limiting Aging Analysis (TLAAs) and include such TLAAs in the LCMPs and in the CAs. OPG to provide commitment that TLAAs necessary to determine the actual conditions of components will be completed. Although the action is complete, this will need to be updated to cover operation past 2020 for

SECTION 2 - GI-22 ASSOCIATED GAPS	
	Pickering Units 1,4 and Units5-8. Therefore, this is a gap for Pickering PSR2. Appendix A Item 69 Include relevant information from COG JP 4271 Calandria and internals. Fitness for Life Extension Guidelines in N-PLAN-01060-10003 *Reactor Components and Structures Life Cycle Management Plan (LCMP)* and submit the LCMP to the CNSC in accordance with Pickering B PROL 08.20/2013 LC 1.2. Although the action is complete, this will need to be updated to cover operation past 2020 for Pickering Units 1,4 and Units 5-8. Therefore, this is a gap for Pickering PSR2. Note: An interim LCMP update for Major Components is documented in P-CORR-01060-0587604 R000, which describes life cycle management strategies for major components to achieve extended operation to 2024. Strategies in this document may apply beyond 2024, but this needs to be confirmed as part of the resolution of this COP related PSR2 gap. Appendix C Item 5 Update the Pickering B HTS aging model. This action is complete but needs to be reviewed to assess impact of operation past 2020 for Pickering Units 1,4 and Units 5-8. Therefore, this is a gap for Pickering PSR2. Appendix C Item 6 Update the Pickering B HTS aging management strategy. This action is complete but needs to be reviewed to assess impact of operation past 2020 for Pickering Units 1,4 and Units 5-8. Therefore, this is a gap for Pickering PSR2. ***COP Review in Support of Safety Factor 4*** **Associated Resolutions:** GI-1-RS1, GI-1-RS3, GI-2-RS1, GI-3-RS1, GI-4-RS1, GI-4-RS2, GI-8-RS1, GI-24-RS1, GI-43-RS3
SF2-AG2	An SF2 Gap related to Time Limiting Elements of Aging Analysis for passive long-lived SSCs for the period of extended operation was identified in [P-CORR-00531-05099, e-Doc 5295534, July 12, 2017]. **Associated Resolutions:** GI-1-RS3, GI-2-RS1, GI-3-RS1, GI-4-RS1, GI-8-RS1, GI-43-RS3

SECTION 3 - GI-22 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains one SF2 Additional Gap and one SF4 Gap related to COP Appendix A Actions #4, 10, 11, 12, 13, 14, 19, 21, 30, 52, 69, and Appendix C Items 5 and 6. A number of these issues are also applicable to Pickering Units 1,4. As shown in the Resolution Plan, all of the items identified in the SF4-18 Gap and the SF2-AG2 Additional Gap are addressed in other GIs.

SECTION 4 - GI-22 PRIORITY DETERMINATION												
Safety Significance of Global Issue	**Deterministic Considerations**			**Probabilistic Considerations**								**Overall Safety Significance Level**
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
												2

Rationale:

This Global Issue consists of gaps arising from reassessment of 13 COP actions for the extended operating period and one SF2 Additional Gap. These gaps are related to fitness for service and safety analysis for events impacted by aging. All of the Resolution Statements for this Global Issue are cross-references to Resolution Statements for other Global Issues (GI-1, GI-2, GI-3, GI-4, GI-8, GI-24 and GI-43). There are no unique Resolution Statements for this Global Issue. As the issues relate to demonstration of fitness for service of SSCs for the extended operating period, and as most fitness for service Global Issues have a Safety Significance Level of 2, the Safety Significance Level assigned to this Global Issue is also 2. OPG activities addressing the Global Issue are underway and they are detailed in GI-1, GI-2, GI-3, GI-4, GI-8, GI-24 and GI-43.

SECTION 5 - GI-22 RESOLUTION PLAN	
GI-22-XRF-GI-1-RS1	The R&D needed to support assurance of Fuel Channel Fitness for Service to 2024 is complete. Complete the additional R&D to support validation of the fracture toughness model. (SF4-18 – COP Appendix A Item #14)
GI-22-XRF-GI-1-RS3	Update the Fuel Channels LCMP [N-PLAN-01060-10002-R017, OPG Plan, *Fuel Channels Life-Cycle Management Plan*, October 2016] for Pickering Units 1,4 for the extended operating period. (SF4-18 – COP Appendix A Item #52) (SF2-AG2)
GI-22-XRF-GI-2-RS1	Update the Feeders LCMP [N-PLAN-01060-10001-R018, OPG Plan, *Feeders Life Cycle Management Plan*, October 2016], based on updated Fitness for Service assessment for Pickering Units 1,4 for the extended operating period. This is covered by GI-2. (SF4-18 – COP Appendix A Item #21 and #52) (SF2-AG2)
GI-22-XRF-GI-3-RS1	Update the Steam Generators LCMP [N-PLAN-33110-10009-R007, OPG Plan, *Steam Generators Life Cycle Management Plan*, October 2016] for Pickering Units 1,4 for the extended operating period. (SF4-18 – COP Appendix A Item #30 and

SECTION 5 - GI-22 RESOLUTION PLAN	
	#52) (SF2-AG2)
GI-22-XRF-GI-4-RS1	Update the Reactor Components and Structures LCMP [N-PLAN-01060-10003-R014, OPG Plan, *Reactor Components and Structures Life Cycle Management Plan*, October 2016] for Pickering Units 1,4 for the extended operating period. (SF4-18 – COP Appendix A Item #52 and #69) (SF2-AG2)
GI-22-XRF-GI-4-RS2	Perform measurements, as required, of CT-LISS nozzle gaps on Units 5-8 to refine the gap closure rates. Using this new measurement data, update analyses as required, to demonstrate Fitness for Service. Implement mitigation strategies if CT-LISS nozzle contact is predicted within the extended operating period. (SF4-18 – COP Appendix A Items #10, #11, #12, #13)
GI-22-XRF-GI-8-RS1	Complete and update Condition Assessments for secondary side pressure retaining components for the extended operating period. (SF4-18 – COP Appendix A Item #30) (SF4-18 – COP Appendix A Item #52) (SF2-AG2)
GI-22-XRF-GI-24-RS1	Update Heat Transport System aging analysis models and perform the required safety analysis of the events most impacted by aging (SBLOCA, LOF and Neutron Overpower (NOP)) to support extended operation as per the existing practices [N-CORR-00531-18427, OPG Correspondence, *Progress Report on OPG Heat Transport System Aging Safety Analysis*, February 24, 2017]. (SF4-18 – COP Appendix A Items #4, #19, Appendix C Items #5, #6)
GI-22-XRF-GI-43-RS3	Prepare Condition Assessments as appropriate for safety-significant civil structures for the extended operating period. Recommendations from these Condition Assessments will be tracked and reported along with those related to GI-8. This applies to non-Containment Safety-Related Civil Structures. (SF4-18 – COP Appendix A Item #52) (SF2-AG2)

B.23. GI-23 ASME N509-1980 and N510-1980 - Air Cleaning Systems

SECTION 1 - GI-23 GLOBAL ISSUE SUMMARY

The goal of GI-23, ASME N509-1980 and N510-1980 – Air Cleaning Systems, is to demonstrate conformance with the requirements of these standards that are applicable to PSR2. This Global Issue comprises one item requiring No Further Action which addresses one COP Review Gap that was identified to be specific to Pickering Units 1,4, since a review of these standards for these Units was not performed. Safety Significance Level 4 is selected for this Global Issue based on deterministic safety significance levels considerations.

The proposed Resolution Plan for this Global Issue is specified as No Further Action, based on the applicability of the closure of this COP item for Pickering Units 5-8. This is because the scope of the PSR2 review specifically relates to nuclear safety, hence the Filtered Air Discharge System (as part of Containment) is the only filtered air or air cleaning system that is within the scope of PSR2, and it was addressed in the Pickering Units 5-8 review.

Safety Significance Level:	4	**Category:**	Programmatic	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-23 ASSOCIATED GAPS

COP-19	A review of Pickering Units 1,4 Non-SOE air cleaning systems against ANSI/ASME N509-1980 and N510-1980 has not been completed. ***Pickering PSR2 Gap COP-19*** **Associated Resolutions:** GI-23-NFA1

SECTION 3 - GI-23 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains one COP Review Gap related to ASME N509-1980 and N510-1980.

The issue is that the Pickering Units 1,4 non-SOE air cleaning systems have not been assessed against ANSI/ASME N509-1980 and N510-1980. Given the scope of the PSR2 review specifically relates to nuclear safety, the Filtered Air Discharge System (FADS) (as part of Containment) is the only filtered air or air cleaning system that is within the scope of PSR2.

For Pickering Units 5-8, a review was completed and COP action closure accepted by the CNSC (refer to page 18 of Appendix A of [NK30-PLAN-00531-00001 R005, OPG Plan, *Pickering 5-8 Continued Operations Plan*, November 2015]). The closure is based on the assessment presented on pages 4 & 5 of Appendix B of [P-LIST-09314-00001-R000, OPG List, *Pickering Consolidated End of Life Action Log*, December, 2012] that concluded that these standards were considered and followed in the design, installation, testing and operation of the FADS and other normal operating ventilation systems, and that Pickering 5-8 is compliant to a high degree to ASME N509/ N510. FADS, which is common

SECTION 3 - GI-23 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

for Pickering 1,4 and 5-8, has already been assessed as part of the Pickering 5-8 compliance review for N509 and N510.

In addition, OPG Report [N-REP-03480-0601454, *Code Review of CSA N288.3.4 for PN, PWMF, DWMF and WWMF High Efficiency Air Cleaning Assemblies*, January 2016], referenced in the PSR2 N288.3.4 code review [P-REP-03680-00021, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 8, 10, 12, 13, 14*, December 2016], did not identify any Gaps specifically related to FADS. The identified Gaps relate to generic test program design and documentation issues. Since FADS is a Containment sub-system and part of a Special Safety System, the filter system has explicit design basis requirements to ensure that the nuclear safety credits are satisfied [NK30-DR-34230-10001 R000, OPG System Design Requirements, *Filtered Air Discharge System*, March 2004]. These are documented in the SOE for Pickering 1,4 and Pickering 5-8, in the Containment Operational Safety Requirements (OSRs) [NA44-OSR-08131.02-00002 R003, OPG Operational Safety Requirements, *Pickering 1-4 Operational Safety Requirements: Negative Pressure Containment*, March 2015], [NK30-OSR-08131.02-00003 R004, OPG Operational Safety Requirements, *Pickering 5-8 Operational Safety Requirements: Negative Pressure Containment*, March 2015], and in the associated OSR Compliance Tables. The Compliance Tables identify the routine operational tests and periodic surveillances specified to provide assurance of filter availability and effectiveness.

SECTION 4 - GI-23 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	N/A	4	**4**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**4**

Rationale:

This Global Issue is related to Pickering Units 1,4 non-SOE air cleaning systems and ANSI/ASME N509-1980/N510-1980. As noted in Section 3 of this Global Issue, the scope of the PSR2 review specifically relates to nuclear safety, so FADS (as part of Containment) is the only filtered air or air cleaning system that is within the scope of PSR2, and closure of the original COP item 19 on this item for Pickering Units 5-8 is also applicable to Pickering Units 1,4. Therefore, no further action is required.

SECTION 4 - GI-23 PRIORITY DETERMINATION
Regarding deterministic considerations, this Global Issue is not associated with a physical nuclear safety barrier, so Defence in Depth (E1) is not applicable. Safety Significance Levels (E2) is assigned Safety Significance Level 4 since resolution of this issue “may help identify areas that need more attention”. Therefore, Safety Significance Level 4 is selected for deterministic considerations. Regarding probabilistic considerations, this Global Issue has no impact on Core Damage Frequency (F1), Defence in Depth (F2), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) or the Environment (F7). Therefore, probabilistic considerations are not applicable. In summary, the overall Safety Significance Level is 4. No further action is required with respect to this Global Issue.

SECTION 5 - GI-23 RESOLUTION PLAN	
GI-23-NFA1	Given the scope of the PSR2 review specifically relates to nuclear safety, FADS (as part of Containment) is the only filtered air or air cleaning system that is within the scope of PSR2. Closure of the original COP item for Pickering Units 5-8 is thus also applicable to Pickering Units 1,4. No further action is required. (COP-19)

B.24. GI-24 Safety Analysis to Support the Extended Operating Period

SECTION 1 - GI-24 GLOBAL ISSUE SUMMARY					
The goal of GI-24, Safety Analysis to Support the Extended Operating Period, is to demonstrate the adequacy of the safety margins of the plant with aged conditions covering the extended operating period. This Global Issue comprises one proposed Resolution Statement addressing two Gaps: one SF5 review task Gap and one COP Additional Gap. Safety Significance Level 2 is selected for this Global Issue based on deterministic defence-in-depth and safety significance levels considerations, as well as probabilistic defence-in-depth considerations. The proposed Resolution Plan for this Global Issue comprises one proposed Resolution Statement to update the aging safety analysis model and perform the required safety analysis. Completion of the proposed Resolution Plan will support and strengthen Levels 2 and 3 defence-in-depth for the extended operating period.					
Safety Significance Level:	2	**Category:**	Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-24 ASSOCIATED GAPS	
SF5-1	Per Review Task #7, the current safety analysis for Pickering 1,4 and 5-8, demonstrates adequate Shutdown System trip coverage until 2017 and 2018 respectively for the Small Break Loss of Coolant Accident (SBLOCA) and Loss of Flow (LOF) scenarios. However, the impact of Heat Transport System (HTS) component aging on the SBLOCA, LOF and Slow Loss of Regulation (LOR) accident scenarios, will need to be further assessed in order to demonstrate adequate safety margins exist beyond 2020, and therefore a Gap exists for Pickering PSR2. It is noted in [N-CORR-00531-16444, *Progress Report on OPG Heat Transport System Aging Safety Analysis*, February 23, 2016], that work is currently underway to perform Safety Analysis to support the initiative to extend Pickering commercial operation to 2024, accounting for possible mitigation strategies of life-limiting aging mechanisms. Note a related Gap has been captured in the Aging Safety Factor Report (PSR2 Gap SF4-18). ***Review Task #7: Capabilities of the Plant in its Current State*** **Associated Resolutions:** GI-24-RS1
COP-AG1	• Demonstrate adequate safety margins to operate Pickering B units from an HTS ageing perspective to Jan 31, 2021. • Update the Pickering B HTS aging model with respect to reactor safety analysis. • Develop the Pickering B HTS Aging Management Strategy and ensure the strategy describes a path forward to 2020. • Update the Neutron Over Power (NOP) analysis for Pickering B. Analysis should

SECTION 2 - GI-24 ASSOCIATED GAPS

incorporate HTS aging effects and impact, if any, on trip set points.

Pickering PSR2 Gap formerly named COP-27

Associated Resolutions: GI-24-RS1

SECTION 3 - GI-24 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains two Gaps related to aging safety analysis.

The most recent progress report on Heat Transport System (HTS) aging safety analysis [N-CORR-00531-18427, OPG Correspondence, *Progress Report on OPG Heat Transport System Aging Safety Analysis*, February 24, 2017] indicates that the analyses for Pickering 1,4 SBLOCA and LOF are valid to January 31, 2019 while those for Pickering 5-8 are valid to June 30, 2019. The progress report [N-CORR-00531-18427, OPG Correspondence, *Progress Report on OPG Heat Transport System Aging Safety Analysis*, February 24, 2017] also indicates planning to perform safety analyses to support Pickering commercial operation to 2024, accounting for possible mitigation strategies of life-limiting aging mechanisms.

SECTION 4 - GI-24 PRIORITY DETERMINATION

	Deterministic Considerations			Probabilistic Considerations								
Safety Significance of Global Issue	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	**Overall Safety Significance Level**
	2	2	**2**	3	2	3	3	N/A	N/A	N/A	**2**	**2**

<u>Rationale:</u>

Resolution of this Global Issue will ensure that deterministic safety analysis accounts for aging effects for the operational life of the station, confirming that deterministic safety analysis acceptance criteria continue to be met when aging effects are accounted for. The ongoing safety analysis program updates the relevant accident analysis to account for aging effects, as well as any physical or operational enhancements that mitigate the effects of aging on safety margins. OPG will ensure that the Pickering safety analysis accurately accounts for the aging effects of the Heat Transport System.

SECTION 4 - GI-24 PRIORITY DETERMINATION

Regarding deterministic considerations, safety analysis does not directly affect the Defence in Depth (E1) barriers. However, the effectiveness of the safety functions which protect against DBAs needs to be confirmed for the extended operating period. Therefore, Safety Significance Level 2 is assigned to Defence in Depth (E1). For Safety Significance Levels (E2), updating the safety analysis to account for aging effects over the operational life of the station will confirm the adequacy of safety margins. Based on past experience, future updates of the safety analysis may identify some potential reduction in margin. Table E2 in the PSR2 Basis Document associates “some reduction in margin” with Safety Significance Level 2, which, therefore, is assigned. Consequently, the overall Safety Significance Level for deterministic considerations is 2.

Regarding probabilistic considerations, Defence in Depth (F2) is assigned a Safety Significance Level of 2. This is based on the third row of Table F2 in the PSR2 Basis Document, which is similar to some potential reduction in margin for deterministic considerations. For conservatism, the highest Safety Significance Level in this row, which is 2, is applied.

With respect to Plant Operability (F4), aging has the potential to impact operating limits, but such impacts are not expected to impact the complexity of plant operation. Therefore, addressing aging effects in the safety analysis places this Global Issue in row 3 of Table F4 of the PSR2 Basis Document, and for conservatism, the highest Safety Significance Level in this row, which is 3, is selected.

Core Damage Frequency (F1) and Public Radiation Safety (F3) are assigned Safety Significance Levels 3, since the initiating events primarily affected by aging have a low contribution to Core Damage Frequency. These initiating events are Small Loss of Coolant, Loss of Flow, and Loss of Regulation. For these events, the calculated doses to the public in the Safety Report are very low and well within regulatory limits, such that the impact of aging is not significant.

Finally, the impact of aging on safety analysis has no direct relation to Occupational Radiation Safety (F5), Emergency Preparedness (F6) or Environment (F7); the safety analysis to address aging does not affect these, so they are not applicable for this Global Issue.

In summary, both deterministic and probabilistic considerations dictate that this Global Issue has a Safety Significance Level of 2. OPG’s ongoing safety analysis program identifies potential aging impacts and addresses them in advance of potential adverse effects on safety margins.

SECTION 5 - GI-24 RESOLUTION PLAN

GI-24-RS1	Update Heat Transport System aging safety analysis models and perform the required safety analysis of the events most impacted by aging (SBLOCA, LOF and Neutron Overpower (NOP)) to support extended operation as per the existing practices [N-CORR-00531-18427, OPG Correspondence, *Progress Report on OPG Heat Transport System Aging Safety Analysis*, February 24, 2017]. (SF5-1) (COP-AG1) This Resolution Statement also includes/addresses GI-22.

B.25. GI-25 Category 3 CANDU Safety Issues

SECTION 1 - GI-25 GLOBAL ISSUE SUMMARY					
The goal of GI-25, Category 3 CANDU Safety Issues, is to resolve outstanding issues within the scope of PSR2 related to Category 3 CANDU Safety Issues. This Global Issue comprises two proposed Resolution Statements addressing four Gaps: one SF1 code review Gap [CSA N290.0-11], one SF5 review task Gap, one SF7 review task Gap, and one COP Review Gap. Safety Significance Level 3 is assigned for this Global Issue based on deterministic safety significance levels considerations. The proposed Resolution Plan primarily comprises completion of ongoing activities to facilitate the re-categorization of these issues to Category 2. Completion of the proposed Resolution Plan will support and strengthen Level 3 defence-in-depth for the extended operating period.					
Safety Significance Level:	3	**Category:**	Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-25 ASSOCIATED GAPS	
SF5-2	Per Review Task #7, for the Large Break Loss of Coolant Accident (LBLOCA) CANDU Safety Issues (CSIs), while the development of the industry's proposed Composite Analytical Approach (CAA) is on-going, the licensing basis of existing CANDU reactors for the LBLOCA scenario will continue to be based on conservative safety analysis for which acceptance criteria are established. For the Category 3 non-LBLOCA CSI, the industry has applied to re-categorize the issue into a lower category based on analytical evidence and actions taken. Since four CSIs applicable to Pickering NGS (three LBLOCA/one non-LBLOCA) are currently in Category 3 and are undergoing further assessment in order to re-classify into a lower category and address operation past 2020, a Gap exists for Pickering PSR2. Note, the 3 LBLOCAs CSIs are also captured as a Gap in the PSR2 Continued Operations Plan (COP) Review Report (PSR2 Gap COP-20) as they relate to Pickering B Integrated Implementation Plan (IIP) Item I09. The 1 non-LBLOCA CSI is also identified as a Gap in the Hazards Analysis Safety Factor Report (PSR2 Gap SF7-1) as it relates to pipe whip. ***Review Task #7: Capabilities of the Plant in its Current State*** **Associated Resolutions:** GI-25-RS1, GI-25-RS2
SF7-1	To address CNSC safety issue CSI-IH 6, the potential for, and possible impacts of, high-energy piping failures in Pickering Units 1,4 must be assessed. This assessment is currently underway as per [OPG Report, P-REP-04960-00001 R002, *Methodology of High-Energy Line Break Assessment for Piping Inside the Pickering Reactor Buildings*, June 14, 2016] and [OPG Correspondence, N-CORR-00531-18288 R000, *Re-Categorization Request for CANDU Safety Issue IH6 for Pickering NGS 5-8 and Status for Pickering NGS 1-4*, December 2016]. Therefore, this has been identified as a PSR2 Gap. ***Review Task #1: Internal and External Hazards in Deterministic and Probabilistic***

SECTION 2 - GI-25 ASSOCIATED GAPS	
	Analyses **Associated Resolutions:** GI-25-RS2
SF1-9	Clause 4.13 of N290.0-11 identifies requirements to address dynamic piping effects. OPG is currently in the process of completing the High Energy Line Break Assessment (HELBA) for Pickering NGS. Preliminary results show that there would be no consequential damage caused by the rupture of high energy pipes inside Containment to safety related equipment, beyond that already accounted for in the Safety Reports. The final HELBA reports for both Pickering Units 5-8 have been completed, while Pickering Units 1,4 are expected to be completed in 2017. Since this work has not been completed for Pickering 1,4, this is identified as a PSR2 Gap. ***Code Review N290.0-11*** **Associated Resolutions:** GI-25-RS2
COP-20	Three LBLOCA CANDU Safety Issues that are applicable to Pickering NGS remain in Category 3 and have not been fully reassessed in order to re-classify into a lower risk category and cover operation past 2020. ***Pickering PSR2 Gap COP-20*** **Associated Resolutions:** GI-25-RS1

SECTION 3 - GI-25 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains four Gaps (one SF1 Gap, one SF5 Gap, one SF7 Gap and one COP Review Gap) related to the remaining Category 3 CANDU Safety Issues (CSIs). These gaps are related to LBLOCA CSIs and CSI-IH6 on high energy piping.

SECTION 4 - GI-25 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	4	3	**3**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**3**

Rationale:

Resolution of this Global Issue will facilitate the reclassification of Category 3 CANDU Safety Issues, namely the CANDU Safety Issues related to Large Break Loss of Coolant Accidents and the CANDU Safety Issue related to high energy piping (IH6). Given the recent progress in addressing the findings of CNSC staff reviews, it is expected that the remaining Category 3 CSIs will be re-categorized to Category 2 (lower significance).

Regarding deterministic considerations, this Global Issue is not directly related to Defence in Depth (E1). However, although no safety barrier is directly impacted, completing the closure criteria for these CANDU Safety Issues will facilitate re-categorization of these CANDU Safety Issues to Category 2. Therefore Safety Significance Level 4 is assigned to Defence in Depth (E1). Safety Significance Levels (E2) is assigned Safety Significance Level 3 since this issue is considered not significant by itself and has been supported by analytical evidence as discussed in Section 5 of this Global Issue. Accordingly, the overall Safety Significance Level for deterministic considerations is 3.

This Global Issue has no direct impact on the probabilistic considerations, i.e., Core Damage Frequency (F1), Defence in Depth (F2), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these probabilistic considerations are not applicable.

In summary, the overall Safety Significance Level is 3. OPG is progressing the required work to complete the re-categorization of IH6 and is working with the industry on completing the re-categorization of the CANDU Safety Issue related to Large Break Loss of Coolant Accidents.

SECTION 5 - GI-25 RESOLUTION PLAN

GI-25-RS1	Complete the re-categorization of the Large Break LOCA (LBLOCA) CANDU Safety Issues to Category 2. OPG submitted an update to CNSC staff on the resolution of the LBLOCA issue [N-CORR-00531-18022, OPG Correspondence, *Resolution of Large Break LOCA (LBLOCA) Safety Analysis Margin Issue*, April

SECTION 5 - GI-25 RESOLUTION PLAN	
	25, 2016]. An OPG update on the status of CSIs and their resolution is submitted to the CNSC annually, the latest being [N-CORR-00531-18052, *Progress Update On Category 3 CANDU Safety Issues - Implementation of Risk Control Measures*, June 15, 2016]. Given the recent progress by industry in addressing the findings of CNSC staff reviews, it is expected that the remaining Category 3 CSIs will be re-categorized to Category 2 in 2017. OPG is actively progressing this work. (SF5-2) (COP-20)
GI-25-RS2	Complete the re-categorization of CANDU Safety Issue CSI-IH6 for Pickering to Category 2. Complete the assessment of the layout of high-energy piping and Safety-Related Systems inside of the Reactor Buildings of Pickering Units 1 and 4 as per [P-REP-04960-00001 R002, OPG Report, *Methodology of High-Energy Line Break Assessment for Piping Inside the Pickering Reactor Buildings*, June 14, 2016]. For Pickering Units 5-8, the assessment is complete [N-CORR-00531-18052, OPG Correspondence, *Progress Update on Category 3 CANDU Safety Issues – Implementation of Risk Control Measures*, June 15, 2016] and a request for re-categorisation has been made [N-CORR-00531-18288, OPG Correspondence, *Re-Categorization Request for CANDU Safety Issue IH6 for Pickering NGS 5-8 and Status for Pickering NGS 1-4*, December 5, 2016]. For Pickering 1,4, a re-categorization request is planned for June 2018 [N-CORR-00531-18618, OPG Correspondence, *Progress Update on Category 3 CANDU Safety Issues – Implementation of Risk Control Measures*, June 23, 2017]. OPG is actively progressing this work. (SF5-2) (SF7-1) (SF1-9)

B.26. GI-26 Emergency Response Projection Software

SECTION 1 - GI-26 GLOBAL ISSUE SUMMARY					
The goal of GI-26, Emergency Response Projection Software, is to enhance the capability of the Emergency Response Projection (ERP) software. This Global Issue comprises one proposed Resolution Statement addressing one SF13 additional review finding Gap. Safety Significance Level 3 is assigned for this Global Issue based on deterministic defence-in-depth and safety significance levels considerations, as well as probabilistic emergency preparedness considerations. The proposed Resolution Plan comprises completion of enhancements to the ERP software capability. Completion of the proposed Resolution Plan will support and strengthen Level 5 defence-in-depth for the extended operating period.					
Safety Significance Level:	3	**Category:**	Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-26 ASSOCIATED GAPS	
SF13-2	Darlington Gap IIP-OI 046 was identified to assess the ERP code for potential enhancements to address multi-unit Beyond Design Basis Event scenarios. The action assigned to this Gap (AR 28175339, TCD Q1 2017) is also applicable for Pickering NGS and is therefore a Gap for Pickering PSR2. ***Additional Review Findings*** **Associated Resolutions:** GI-26-RS1

SECTION 3 - GI-26 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains one SF13 Gap related to Emergency Response Projection software.

Darlington Gap IIP-OI 046 was identified to assess the Emergency Response Projection (ERP) code for potential enhancements to address multi-unit BDBA scenarios. The above assessment is complete and enhancements, which are also applicable to PNGS, are in progress [N-CORR-00531-18136, OPG Correspondence, *Status Update for Action Item 2016-OPG-7469: Implementation of Emergency Response Projection Computer Code Upgrades*, July 22, 2016].

OPG and Bruce Power are currently performing a project to update their emergency response projection tools. The project is adopting the Unified RASCAL Interface (URI) which is widely used by USA utilities. The project main tasks include:

- The development and deployment of a URI model for each of Darlington, Pickering and Bruce sites for use by the Emergency Response Organization (ERO) to project off-site consequences while an accident is in progress.

SECTION 3 - GI-26 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

- Development and delivery of training for the URI model.

SECTION 4 - GI-26 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	3	3	**3**	N/A	N/A	N/A	N/A	N/A	3	N/A	**3**	**3**

Rationale:

Resolution of this Global Issue will enhance the capability of the Emergency Response Projection software. This issue is being addressed and, as discussed in Section 5 of this Global Issue, an updated tool for emergency response projection is currently under development.

Regarding deterministic considerations, this Global Issue is related to enhancement of software and is not directly related to Defence in Depth (E1). However, the level of operational performance in responding to emergency situations would be impacted (improved) by addressing this issue and accordingly Defence in Depth (E1) is assigned Safety Significance Level 3. Similarly, Safety Significance Levels (E2) is Safety Significance Level 3 since this issue is not considered significant by itself. Accordingly, the overall Safety Significance Level for deterministic considerations is 3.

With respect to probabilistic considerations, Emergency Preparedness (F6) is assigned Safety Significance Level 3 since Emergency Preparedness procedures will be updated to incorporate the new updated software for emergency response projection.

This Global Issue has no direct impact on the other probabilistic considerations, i.e., Core Damage Frequency (F1), Defence in Depth (F2), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), and Environment (F7). Therefore, these probabilistic considerations are not applicable.

In summary, the overall Safety Significance Level is 3. OPG is progressing the required work to update the tool for emergency response projection.

SECTION 5 - GI-26 RESOLUTION PLAN	
GI-26-RS1	Complete the emergency response projection enhancements identified in OPG Correspondence [N-CORR-00531-18136, *Status Update for Action Item 2016-OPG-7469: Implementation of Emergency Response Projection Computer Code Upgrades*, July 22, 2016], which are currently underway. (SF13-2)

B.27. GI-27 Pickering 1,4 Probabilistic Safety Assessment

SECTION 1 - GI-27 GLOBAL ISSUE SUMMARY					
The goal of GI-27, Pickering 1,4 Probabilistic Safety Assessment (PSA), is to further enhance margins to the PSA Safety Goals. This Global Issue comprises two proposed Resolution Statements and one Cross Reference to GI-40 (Accident Management) which address six Gaps: two SF6 review task Gaps, one FAI Additional Gap, two SF6 Additional Gaps and one SF1 Additional Gap related to achieving the Administrative Safety Goals for Pickering 1,4 (Pickering 5-8 meet these goals). Safety Significance Level 3 is assigned for this Global Issue based on the probabilistic considerations of core damage frequency and public radiation safety. The proposed Resolution Plan comprises activities to further improve Pickering 1,4 Severe Core Damage Frequency and Large Release Frequency and to complete the planned Phase 2 Emergency Mitigating Equipment implementation. Completion of the proposed Resolution Plan will support and strengthen Level 3 and 4 defence-in-depth for the extended operating period.					
Safety Significance Level:	3	**Category:**	Engineering, Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-27 ASSOCIATED GAPS	
SF6-1	When each hazard is considered individually by reactor, the time-average Severe Core Damage Frequency Probabilistic Safety Assessment PSA results for certain S-294 PSA elements, in Table 3, are above the OPG specified Administrative Safety Goal (10^{-5}/y), but within the OPG Safety Goal (10^{-4}/y). After incorporating the PSA updates that include certain Fukushima enhancements, only the Pickering Units 1,4 at-power fire risk remains above the OPG specified Administrative Safety Goal for Severe Core Damage Frequency. The PSA results described in this PSR2 report, however, do not incorporate certain proposed analysis enhancements and do not necessarily reflect the latest risk reduction activities currently underway at OPG. ***Review Task #5: Compliance with Safety Criteria*** **Associated Resolutions:** GI-27-RS1, GI-27-RS2, GI-40-RS1
SF6-2	When each hazard is considered individually by reactor, the time-average Large Release Frequency Probabilistic Safety Assessment (PSA) results for certain S-294 PSA elements, in Table 4, are above the OPG specified Administrative Safety Goal (10^{-6}/y) but within the OPG Safety Goal (10^{-5}/y). After incorporating the PSA updates that include certain Fukushima enhancements, only the Pickering Units 1,4 at-power internal events and at-power fire risks remain above the OPG specified Administrative Safety Goal for Large Release Frequency. The PSA results described in this PSR2 report, however, do not incorporate certain proposed analysis enhancements and do not necessarily reflect the latest risk reduction activities currently underway at OPG. ***Review Task #5: Compliance with Safety Criteria***

SECTION 2 - GI-27 ASSOCIATED GAPS	
	Associated Resolutions: GI-27-RS1, GI-27-RS2, GI-40-RS1
FAI-AG1	An FAI Gap related to the need for further safety enhancements to control long term radiological releases and, to the extent practicable unfiltered releases, following a BDBA, was identified in [P-CORR-00531-05003, e-Doc 5210355, March 22, 2017]. **Associated Resolutions:** GI-27-RS2
SF6-AG2	An SF6 Gap related to Further Safety Enhancements to Support Severe Accident Management, particularly hydrogen source term management, computational tools and venting effectiveness, was identified in [P-CORR-00531-05090, e-Doc 5289137, June 30, 2017]. **Associated Resolutions:** GI-27-RS2
SF6-AG3	An SF6 Gap related to station-specific investigations on Calandria vessel integrity during core degradation and in-vessel retention, and structural and stress analyses of the Pickering Calandria vessel under severe accident conditions, was identified in [P-CORR-00531-05090, e-Doc 5289137, June 30, 2017]. **Associated Resolutions:** GI-27-RS2
SF1-AG16	An SF1 Gap related to installation of additional means of Hydrogen Monitoring in Containment, in order to benchmark computational aids used in SAMG, was identified in [P-CORR-00531-05107, e-Doc 5305945, July 26, 2017]. **Associated Resolutions:** GI-27-RS2

SECTION 3 - GI-27 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains two SF6 Gaps and four Additional Gaps.

The following Pickering Units 1,4 Probabilistic Safety Assessments are identified as not achieving the OPG specified Administrative Safety Goals but complying with the OPG Safety Goals:

- At-Power Fire for Severe Core Damage Frequency
- At-Power Internal Events and At-Power Fire for Large Release Frequency

A review of the Fukushima Actions performed for PSR2 is documented in [P-REP-03680-00022, OPG Report, *Fukushima Action Item Review in Support of PNGS Periodic Safety Review 2 (PSR2)*, February 6, 2017] and [P-CORR-03680-0586481, OPG Memorandum, *Pickering NGS Extended Operations – Reassessment of Fukushima Action Item 1.3.1 & 1.3.2 – Containment Integrity*, November 30, 2016]. The report considered enhancements to safety that had already been made as well as enhancements that were underway or committed. These actions, discussed in the reports, will also address the six Gaps associated with this Global Issue, and are described in the two proposed Resolution Statements for this Global Issue and the Cross-Reference to a GI-40 proposed Resolution Statement.

SECTION 4 - GI-27 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	N/A	N/A	**N/A**	3	N/A	3	N/A	N/A	N/A	N/A	**3**	**3**

Rationale:

Resolution of this Global Issue will further improve the calculated Pickering 1,4 Severe Core Damage Frequency and Large Release Frequency.

This Global Issue pertains specifically to the Pickering NGS Probabilistic Safety Assessment. Therefore, deterministic considerations, Defence in Depth (E1) and Safety Significance Levels (E2), are not applicable to this Global Issue.

Regarding probabilistic considerations, this issue is assigned Safety Significance Level 3 with respect to Core Damage Frequency (F1) since the expected reduction in Core Damage Frequency as a result of addressing this issue is 10^{-7} to 10^{-6}/y. Public Radiation Safety (F3) is not directly related to this issue and limited to issues with potential change in dose for events with initiating frequencies > 10^{-5}/y. However, Safety Significance Level 3 is selected on the basis that the expected reduction in Large Release Frequency for Pickering 1,4 as a result of addressing this issue is in the order of 10^{-7}/y and consequently a corresponding risk reduction will be achieved with respect to public dose for severe accidents. This Global Issue has no direct impact on the other probabilistic considerations, i.e., Defence in Depth (F2), Plant Operability (F4), Occupational Radiation Dose (F5), Emergency Preparedness (F6), and Environment (F7). Therefore, these probabilistic considerations are not applicable.

In summary, the overall Safety Significance Level is 3. OPG is actively progressing this work in support of extended operation at Pickering NGS.

SECTION 5 - GI-27 RESOLUTION PLAN

GI-27-RS1	Complete actions from PSA improvement Plan [P-CORR-00531-04946, OPG Correspondence, *Pickering NGS: Risk Improvement Plan Update*, February 28, 2017]. OPG is progressing this work. (SF6-1) (SF6-2)

SECTION 5 - GI-27 RESOLUTION PLAN	
GI-27-RS2	Investigate and implement additional practicable design, operational and/or analytical enhancements to further improve Pickering 1,4 Severe Core Damage Frequency and Large Release Frequency (e.g., alternative emergency cooling water makeup). (SF6-1) (SF6-2) (FAI-AG1) (SF6-AG2) (SF6-AG3) (SF1-AG16) This Resolution Statement is related to GI-40.
GI-27-XRF-GI-40-RS1	Complete the planned Phase 2 EME implementation. This includes supplying cooling water, and power to essential loads via EME generators, to allow for operation of Air Cooling Units (ACUs) and Hydrogen Igniters [P-CORR-00531-04945, OPG Correspondence, *Pickering NGS – CNSC Action Item 2016-48-7470 Status Update on Emergency Mitigating Equipment and Telecommunications Projects*, February 16, 2017]. OPG is actively progressing this work in support of extended operation at Pickering NGS. (SF6-1) (SF6-2)

B.28. GI-28 Reactivity Worth of Control Absorbers

SECTION 1 - GI-28 GLOBAL ISSUE SUMMARY					
The goal of GI-28, Reactivity Worth of Control Absorbers, is to confirm that the Pickering 5-8 Control Absorbers will have adequate reactivity worth through the period of extended operation (Pickering 1,4 reactors do not have Control Absorbers). This Global issue comprises one item requiring No Further Action which addresses one COP Review Gap. Safety Significance Level 3 is assigned for this Global Issue based on both deterministic and probabilistic defence-in-depth considerations. The proposed Resolution Plan is No Further Action based on an assessment which demonstrates acceptable reactivity worth of the Control Absorbers over the extended operating period.					
Safety Significance Level:	3	**Category:**	Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-28 ASSOCIATED GAPS	
COP-7	Demonstration of adequate margin to operate the Pickering 5-8 RRS Control Absorbers through the period of extended operation by performing engineering analysis of RRS control absorber cadmium to demonstrate adequate reactivity-worth, has not been completed. ***Pickering PSR2 Gap COP-7*** **Associated Resolutions:** GI-28-NFA1

SECTION 3 - GI-28 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains one COP Review Gap related to reactivity worth of the Pickering Units 5-8 Reactor Regulating System (RRS) Control Absorbers. This gap identifies the need to demonstrate that the reactivity worth of the Control Absorber cadmium is adequate for the extended operating period.

SECTION 4 - GI-28 PRIORITY DETERMINATION

	Deterministic Considerations			Probabilistic Considerations								
Safety Significance of Global Issue	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	**Overall Safety Significance Level**
	3	N/A	**3**	4	3	N/A	4	N/A	N/A	N/A	**3**	**3**

Rationale:

Resolution of this Global Issue confirms that the reactivity worth of the Control Absorber cadmium is adequate for the extended operating period. As discussed in Section 5 of this Global Issue, a review of previous work has confirmed that the change in the reactivity worth of the Reactor Regulating System Control Absorbers over the extended operating period is acceptable. Nevertheless, the Safety Significance of this Global Issue is determined here in accordance with the Global Assessment process.

This Global Issue has Safety Significance Level 3 for deterministic considerations with respect to Defence in Depth (E1) since it is related to confirmation of the adequacy of the reactor control safety function, and the issue does not impair the capability of safety provisions to terminate an anticipated event. Safety Significance Levels (E2) is considered not applicable, since this Global Issue potentially impacts a physical nuclear safety barrier, whereas E2 primarily relates to issues that impact other objectives or are indirectly related to nuclear safety. Hence, the overall Safety Significance Level of 3 for deterministic considerations is dictated by the E1 categorization.

With respect to probabilistic considerations, Defence in Depth (F2) is assigned Safety Significance Level 3 on the basis that resolution of this issue prevents at most a partial loss of safety margin, so the bottom row of Table F2 in the PSR2 basis document is applicable. The most conservative Safety Significance Level for this row is selected, i.e., Safety Significance Level 3. This Global Issue has insignificant impact (less than 10^{-7}/y) on the Reactor Core Damage Frequency (F1) and this consideration is accordingly assigned Safety Significance Level 4. Similarly, this Global Issue has insignificant impact on Plant Operability (F4), i.e., ~ 0.001 probability that the issue requires or leads to an extended period of plant shutdown. Therefore, Safety Significance Level 4 is assigned to Plant Operability (F4).

This Global Issue has no direct impact on the other probabilistic considerations, i.e., Public Radiation Safety (F3), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these probabilistic considerations are not applicable. Based on this, the overall Safety Significance Level for probabilistic considerations is 3.

In summary, both deterministic and probabilistic considerations dictate that this Global Issue has

SECTION 4 - GI-28 PRIORITY DETERMINATION
Safety Significance Level 3. However, as discussed in Section 5 of this Global Issue, the change in the reactivity worth of the Reactor Regulating System Control Absorbers over the extended operating period has been confirmed to be acceptable and no further work is required on this issue.

SECTION 5 - GI-28 RESOLUTION PLAN	
GI-28-NFA1	The change in the reactivity worth of the RRS Control Absorbers over the extended operating period is acceptable [P-CORR-03680-0620822, *Pickering NGS PSR2 – Reactivity Worth of Pickering 5-8 Control Absorbers*, June 9, 2017]. The Control Absorbers are positioned outside of the reactor core for the large majority of the time. No further action is required. (COP-7)

B.29. GI-29 FFS of the Fuelling Machines and FM Bridge Ball Screws for the Extended Operating Period

SECTION 1 - GI-29 GLOBAL ISSUE SUMMARY					
The goal of GI-29, FFS of the Fuelling Machines and FM Bridge Ball Screws for the Extended Operating Period, is to ensure that the Fueling Machines remain fit for service for the extended operating period. This Global Issue comprises one Cross Reference to GI-8 which addresses two COP Review Gaps. Safety Significance Level 2 is assigned for this Global Issue based on both deterministic and probabilistic defence-in-depth and plant operability considerations. The proposed Resolution Plan consists of a cross-reference to one GI-8 (Completion/Updating of the Condition Assessment) proposed Resolution Statement to complete the Condition Assessments for the FM and FM Bridge Ball Screws. Completion of the proposed Resolution Plan will support and strengthen Level 1 defence-in-depth for the extended operating period.					
Safety Significance Level:	2	**Category:**	Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-29 ASSOCIATED GAPS	
COP-5	The fatigue analysis of the Pickering Fuelling Machine components has not been completed to demonstrate adequate margin to operate the Fuelling Machines for the extended operation period and for the period beyond where required for defueling activities. ***Pickering PSR2 Gap COP-5*** **Associated Resolutions:** GI-8-RS1
COP-6	Demonstration of adequate margin to operate the Pickering Fuelling Machine Bridge ball screws for the extended operation period and for the period beyond as required for defueling activities by performing engineering analysis of fatigue and aging of bridge ball screws, has not been completed. ***Pickering PSR2 Gap COP-6*** **Associated Resolutions:** GI-8-RS1

SECTION 3 - GI-29 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains two COP Review Gaps related to the condition of Fuel Machines and Machine Bridge ball screws.

SECTION 4 - GI-29 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	2	N/A	**2**	4	2	4	2	4	N/A	N/A	**2**	**2**

Rationale:

Resolution of this Global Issue will ensure the fitness for service of Fuelling Machines for the extended operating period. As discussed in Section 3 of this Global Issue, Condition Assessments, including those for Fuelling Machines and Fuelling Machine Ball Screws, are in progress.

This Global Issue has Safety Significance Level 2 for deterministic considerations with respect to Defence in Depth (E1). This is because the fitness for service of Fuelling Machines is required to ensure that the issue does not impact the Primary Heat Transport pressure boundary. Safety Significance Levels (E2) is considered not applicable because this Global Issue potentially impacts a physical nuclear safety barrier, whereas E2 primarily relates to issues that impact other objectives or that are indirectly related to nuclear safety. Hence, the overall Safety Significance Level of 2 for deterministic considerations is dictated by the E1 categorization.

With respect to probabilistic considerations, the Fuelling Machines become part of Primary Heat Transport pressure boundary during fuelling. Resolving this Global Issue would preclude a potential reduction in the reliability of the Fuelling Machines for anticipated events (third row of Table F2 in the PSR2 Basis Document). The highest Safety Significance Level of 2 is assigned to Defence in Depth (F2) to conservatively cover initiating events of frequency of approximately 10^{-2}/y. Similarly, the Safety Significance Level with respect to Plant Operability (F4) is also 2, because an extended period of plant shutdown as a result of this issue is expected to have a probability less than 0.1. The issue has insignificant impact on Public Radiation Safety (F3) and Occupational Radiation Safety (F5), and therefore Safety Significance Level 4 is assigned for these considerations.

A Safety Significance Level of 4 is assigned to Core Damage Frequency (F1) since the Global Issue has insignificant impact on CDF. The other probabilistic considerations, i.e., Emergency Preparedness (F6), and Environment (F7) are not directly applicable to this Global Issue.

In summary, the overall Safety Significance Level is 2. OPG is progressing the required work to ensure the fitness for service of the Fuelling Machines for the extended operating period.

SECTION 5 - GI-29 RESOLUTION PLAN	
GI-29-XRF-GI-8-RS1	Complete the Condition Assessments for the Fuelling Machines and FM Ball Screws. (COP-5) (COP-6)

B.30. GI-30 Evaluation of Instantaneous Risk

SECTION 1 - GI-30 GLOBAL ISSUE SUMMARY					
The goal of GI-30, Evaluation of Instantaneous Risk, is to enhance Safety Goal monitoring. This Global Issue comprises one Acceptable Deviation addressing one SF6 review task Gap. Safety Significance Level 3 is assigned for this Global Issue based on deterministic defence-in-depth considerations and probabilistic defence-in-depth and core damage frequency considerations. The proposed Resolution Plan comprises an Acceptable Deviation because OPG continues to participate in an industry initiative on evaluation of instantaneous risk, and because of the low safety significance of this issue and the existence of other deterministic rules at Pickering NGS that provide assurance of defence-in-depth during temporary outage or maintenance alignments.					
Safety Significance Level:	3	**Category:**	Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-30 ASSOCIATED GAPS	
SF6-3	Although the OPG instantaneous risk Safety Goals apply to Level 1 and Level 2 Probabilistic Safety Assessment (PSA) for all hazards, current practice at Pickering NGS is that instantaneous risk is only evaluated using the Level 1 at-power internal events and Level 1 outage internal events PSA models. This is similar to current practices at other Canadian utilities. There are other deterministic rules at Pickering NGS that provide assurance of defence-in-depth during temporary outage or maintenance alignments, and these deterministic considerations apply regardless of the potential hazard. Work is underway, via an industry initiative, to develop methodologies for assessment of instantaneous risk from other hazards included in the PSA. ***Review Task #5: Compliance with Safety Criteria*** **Associated Resolutions:** GI-30-AD1

SECTION 3 - GI-30 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains one SF6 Gap related to the assessment of instantaneous risk. The current scope of OPG instantaneous risk evaluation involves use of Level 1 Internal Events At-Power and Outage PSA models.

SECTION 4 - GI-30 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	3	N/A	**3**	3	3	N/A	N/A	N/A	N/A	N/A	**3**	**3**

Rationale:

The current scope of OPG instantaneous risk evaluation involves use of Level 1 Internal Events At-Power and Outage Probabilistic Safety Assessment models. As discussed in Section 3 of this Global Issue, At-Power and Outage instantaneous risk Safety Goal monitoring is already proceduralized and implemented regularly for online maintenance and during each unit outage. OPG is continuing to participate in the industry initiative on evaluation of instantaneous risk.

Regarding deterministic considerations, this Global Issue is assigned Safety Significance Level 3 for Defence in Depth (E1), since the issue is related to potential enhancement in the level of operational performance. Safety Significance Levels (E2) is considered not applicable since this Global Issue can have a direct impact on nuclear safety, whereas E2 primarily relates to issues that are indirectly related to nuclear safety. Hence, the overall Safety Significance Level of 3 for deterministic considerations is dictated by the E1 categorization.

With respect to probabilistic considerations, Core Damage Frequency (F1) is assigned Safety Significance Level 3 on the basis that enhancements to the method for evaluating instantaneous risk will have a small impact on the overall core damage frequency, not exceeding a change greater than 10^{-6}/y. Defence in Depth (F2) is assigned Safety Significance Level 3 on the basis that the issue is related to the reliability/availability of the heat sink during online maintenance or a unit outage. The highest level is conservatively selected (the bottom row of Table F2 in the PSR2 Basis Document). This Global Issue has no direct impact on the other probabilistic considerations, i.e., Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Hence, the overall Safety Significance Level of 3 for probabilistic considerations is dictated by the Core Damage Frequency (F1) and Defence in Depth (F2) categorizations.

In summary, the overall Safety Significance Level is 3. OPG is continuing to participate in the industry initiative on methods for evaluating instantaneous risk.

SECTION 5 - GI-30 RESOLUTION PLAN	
GI-30-AD1	An industry initiative is underway to develop methodology and processes for evaluation of instantaneous risk. The current instantaneous risk Safety Goal monitoring is developed using the At-Power and Outage Internal Events PSA models. At-Power and Outage instantaneous risk Safety Goal monitoring is already proceduralized and implemented regularly for online maintenance and during each unit outage. This is similar to current practices at other Canadian utilities. There are other deterministic rules at Pickering NGS that provide assurance of defence-in-depth during temporary outage or maintenance alignments, and these deterministic considerations apply regardless of the potential hazard. OPG is continuing to participate in the industry initiative on evaluation of instantaneous risk. Per the low safety significance (Safety Significance Level 3), this is assessed as an Acceptable Deviation. (SF6-3)

B.31. GI-31 Deterministic Safety Analysis

SECTION 1 - GI-31 GLOBAL ISSUE SUMMARY					
The goal of GI-31, Deterministic Safety Analysis, is to complete the implementation of [N-PLAN-03500-0500515 R003, *REGDOC-2.4.1 Implementation Plan*, May 2015] for CNSC Regulatory Document REGDOC-2.4.1, *Deterministic Safety Analysis*, using a graded approach as permitted by the REGDOC, and update the plan in the context of extended operation. This Global Issue comprises two proposed Resolution Statements, two Acceptable Deviations, one item requiring No Further Action and one cross-reference to GI-44, which address 12 Gaps: five SF1 Gaps related to requirements for Anticipated Operational Occurrences (AOOs) in design-related codes, three SF5 Gaps and one COP Review Gap related to the implementation of REGDOC-2.4.1 requirements, one COP Review Gap related to the Boiling Length Average Critical Heat Flux correlation for 28-element fuel and two Additional Gaps. GI-31 is Safety Significance Level 3 based on deterministic safety significance levels considerations. The proposed Resolution Plan for GI-31 primarily comprises activities to update the REGDOC-2.4.1 Implementation Plan to include consideration of the extended operating period. These activities address two of the SF5 Gaps and one of the COP Review Gaps. Two Acceptable Deviations address the SF1 Gaps, the remaining SF5 Gap and one of the SF5 Additional Gaps. The other SF5 Additional Gap is addressed by a Cross-Reference to GI-44. No Further Action is required to address the COP Review Gap on the critical heat flux correlation because this item has been closed by the CNSC. Completion of the proposed Resolution Plan will support and strengthen Levels 2 and 3 defence-in-depth for the extended operating period.					
Safety Significance Level:	3	**Category:**	Programmatic, Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-31 ASSOCIATED GAPS	
SF5-3	The REGDOC-2.4.1 Implementation Plan and associated gap assessments capture all gaps related to REGDOC-2.4.1 and incorporate a systematic selection of the scope of work to address the most pertinent gaps in accordance with the graded approach to upgrading existing analyses. REGDOC-2.4.1 compliant analysis activities and progress related to REGDOC-2.4.1 implementation in the Pickering Licence Conditions Handbooks are tracked according to the CNSC Compliance Verification Criteria. Since the implementation is in progress, this has been identified as a PSR2 gap for Pickering NGS REGDOC-2.4.1 compliance. ***Code Review CNSC REGDOC-2.4.1*** **Associated Resolutions:** GI-31-RS1
SF5-4	As described in the REGDOC-2.4.1 Implementation Plan: "Limited upgrades are proposed in the Pickering A and B Plan, which has been developed with consideration for demonstration of continued safe operation while accounting for the limited remaining operating life of the Pickering Units". The REGDOC-2.4.1 Implementation Plan for Pickering did not consider

SECTION 2 - GI-31 ASSOCIATED GAPS	
	operation past 2020 and therefore the need for review and update of the Implementation Plan in the context of operation of Pickering NGS beyond 2020 is identified as a PSR2 gap. This will be informed by the timeline of the Darlington REGDOC-2.4.1 Implementation Plan, and the limited additional years of Pickering NGS operation. ***Code Review CNSC REGDOC-2.4.1*** **Associated Resolutions:** GI-31-RS2
SF1-8	Clause 4.2 of N290.0-11 requires that Plant States be grouped into several categories, including Anticipated Operational Occurrences (AOOs). This is consistent with clauses of REGDOC-2.4.1 and REGDOC-2.5.2 related to identification and classification of initiating events. Since AOOs have not been identified and analyzed in the current Pickering Safety Reports, the requirements and credits attributed to the Special Safety Systems for AOOs, if any, cannot be readily ascertained. This issue has therefore been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation. ***Code Review N290.0-11*** **Associated Resolutions:** GI-31-AD1
COP-21	The updates to the Safety Reports are being conducted in accordance with the REGDOC-2.4.1 Implementation Plan (REGDOC-2.4.1 superseded CNSC RD-310). This plan did not consider operation beyond 2020, for Pickering Units 1,4 and Units 5-8. ***Pickering PSR2 gap COP-21*** **Associated Resolutions:** GI-31-RS2
SF5-6	Safety Report upgrades currently underway for Pickering as part of REGDOC-2.4.1 implementation for the period of 2017-2021 will utilize methods consistent with N288.2-14. The REGDOC-2.4.1 Implementation Plan update will consider the incremental implications of Pickering operation beyond 2020, including any considerations of N288.2 revisions. This issue has therefore been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation. ***Code Review N288.2-14*** **Associated Resolutions:** GI-31-AD2
COP-14	There are remaining issues from AI 201113-2297 follow-up related to providing a detailed assessment report of the uncertainty in the implementation and use of BLA CHF correlation for 28 element fuel. ***Pickering PSR2 Gap COP-14*** • **Note – Per GI-31-NFA1, this gap has been fully addressed.** **Associated Resolutions:** GI-31-NFA1
SF1-14	Clause 4.2 and Clause 5.19 of CSA N290.4-11 require the capability of the Reactor Regulating System (RRS) to be assessed to deal with the Anticipated Operational

SECTION 2 - GI-31 ASSOCIATED GAPS	
	Occurrences (AOOs), by preventing them from escalating into Design Basis Accidents (DBAs) that would require Shutdown System action. In general the setback function (and stepback in Pickering Units 5-8) addresses this requirement; however AOOs have not been identified and analyzed in the current Pickering Safety Reports. Therefore, this has been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation. Note: There are also additional clauses which refer to requirements of RRS during AOOs (Clauses 5.6.2, 5.19, 5.16.1); however, for convenience, all issues related to AOO requirements for RRS in N290.4-11 are captured under this one PSR2 gap. ***Code Review N290.4-11*** **Associated Resolutions:** GI-31-AD1
SF1-15	A gap exists for the Pickering Units 1,4 and 5-8 Instrument Air and Electrical Systems on clauses 7.1 and 7.4.2 of N290.5-06 (R2011) including Update No. 1 dealing with requirements for Anticipated Operational Occurrences (AOOs). These clauses introduce the requirement for components to be qualified to perform their required functions during normal operation and AOOs. Only the portion of this clause on AOOs is pertinent to nuclear safety. It is likely that AOOs, due to their nature, do not result in a challenge to the qualification of systems, including Instrument Air and Electrical systems. However, AOOs have not been identified and analyzed in the current Pickering Safety Reports. This issue has therefore been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation. ***Code Review N290.5-06*** **Associated Resolutions:** GI-31-AD1
SF1-16	The CSA N290.11-13 Clause 5.1.1 to 5.1.5 requirement for back-up heat sinks to mitigate the conditions following an Anticipated Operational Occurrence (AOO) is not specified in governance/procedures. Loss of a division of power, a single component failure, etc., which are likely to be in the set of AOOs, are accounted for in the specification of heat sinks. However, AOOs have not been identified and analyzed in the current Pickering Safety Reports. This issue is therefore a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation. ***Code Review N290.11-13*** **Associated Resolutions:** GI-31-AD1
SF1-18	Clause 5.6.1 of CSA N290.11-13 requires that the designed reliability for process heat sinks be consistent with Anticipated Operational Occurrence (AOO) frequency limits, such that an emergency heat sink does not need to be used for an AOO. AOOs have not been identified and analyzed in the current Pickering Safety Reports. This issue is therefore a PSR2 gap and is being addressed as part of REGDOC-2.4.1 implementation. ***Code Review N290.11-13*** **Associated Resolutions:** GI-31-AD1
SF1-	An SF1 Gap related to addressing analysis of Anticipated Operational Occurrences was

SECTION 2 - GI-31 ASSOCIATED GAPS	
AG14	identified in [P-CORR-00531-05107, e-Doc 5305945, July 26, 2017]. **Associated Resolutions:** GI-31-AD1
SF5-AG1	An SF5 Gap related to requirements for the Credit of Operator Action Times in REGDOC-2.4.1 and REGDOC-2.5.2, and justification for which operation action times are credited in safety analysis, was identified in [P-CORR-00531-05090, e-Doc 5289137, June 30, 2017]. **Associated Resolutions:** GI-44-AD8

SECTION 3 - GI-31 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains 12 Gaps (five SF1 gaps, three SF5 gaps and 2 COP Review Gaps, one SF1 Additional Gap and one SF5 Additional Gap) related to Deterministic Safety Analysis and REGDOC-2.4.1 implementation. This Global Issue includes a number of gaps arising from AOOs requirements in design-related codes. These gaps have been consolidated into this Global Issue as AOOs have not been identified and analyzed in the current Pickering Safety Reports. Consideration of the identification and analysis of AOOs is addressed under REGDOC-2.4.1 implementation.

Compliance with REGDOC-2.4.1 is currently a licensing requirement for Pickering NGS (per PROL 48.03/2018) as indicated in Appendix C.2 of the R05 Pickering Licence Conditions Handbook. REGDOC-2.4.1 allows a graded approach to upgrading existing analyses.

OPG submitted a progress report on OPG's Safety Analysis Improvement and REGDOC-2.4.1 implementation activities and acknowledged the closing of Action Item 2014-OPG-5461 as per CNSC Correspondence [N-CORR-00531-18016, e-Doc 4947467, *Darlington & Pickering NGS: Safety Analysis Improvement and REGDOC-2.4.1 Implementation - Closure of Action Item 2014-OPG-5461*, March 24, 2016]. Attachment 1 of [N-CORR-00531-18239, OPG Correspondence, *Progress Report on OPG Safety Analysis Improvement and REGDOC-2.4.1 Implementation*, October 17, 2016] provides a progress update on REGDOC-2.4.1 compliant safety analyses.

As stated in the Licence Conditions Handbook [P-CORR-00531-04886, e-Doc 5121102, *Pickering NGS: Licence Conditions Handbook, LCH-PNGS-R005*, November 10, 2016], the current REGDOC-2.4.1 implementation plan defines the REGDOC-2.4.1 compliant analyses to be undertaken in the 2014-2017 timeframe. OPG is to update its REGDOC-2.4.1 Implementation Plan at the end of 2017, applying a graded, safety significant approach. The updated plan will identify any changes required to support the continued safe operation of Pickering NGS, and will be informed by the timeline of the Darlington REGDOC-2.4.1 Implementation Plan and the limited additional years of Pickering NGS operation.

SECTION 4 - GI-31 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	N/A	3	**3**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**3**

Rationale:

This Global Issue is related to Deterministic Safety Analysis and REGDOC-2.4.1 implementation. As discussed in Section 3 of this Global Issue, OPG will update its REGDOC-2.4.1 Implementation Plan by the end of 2017, including consideration of the impact of the extended operating period. OPG's existing deterministic safety analysis is comprehensive and robust.

Regarding deterministic considerations, this Global Issue pertains to analysis and is not directly related to any physical barriers. Therefore, this Global Issue is not directly applicable to Defence in Depth (E1). Safety Significance Levels (E2) is assigned Safety Significance Level 3 since the issue is not significant by itself (the definition of Safety Significance Level 3 for E2) and OPG will update its REGDOC-2.4.1 Implementation Plan by the end of 2017. Hence, the overall Safety Significance Level of 3 for deterministic considerations is dictated by the E2 categorization.

This Global Issue pertains to deterministic safety analysis, so has no direct impact on the probabilistic considerations, i.e., Core Damage Frequency (F1), Defence in Depth (F2), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, the probabilistic considerations are not directly applicable to this issue.

In summary, the overall Safety Significance Level is 3. OPG continues to update Pickering deterministic safety analysis as mandated by the Licence Conditions Handbook, and work is progressing to update the REGDOC-2.4.1 Implementation Plan using a graded approach with consideration of the impact of the extended operating period.

SECTION 5 - GI-31 RESOLUTION PLAN

GI-31-RS1	Complete the Pickering NGS Implementation Plan for REGDOC-2.4.1 [N-PLAN-03500-0500515 R003, *REGDOC-2.4.1 Implementation Plan*, May 25, 2015]. The Implementation Plan at Pickering NGS was summarized in the PROL Amendment request as follows: "In alignment with current Pickering licensing requirements, and with the graded approach permitted by REGDOC-2.4.1 requirements, OPG

SECTION 5 - GI-31 RESOLUTION PLAN	
	will be upgrading the Pickering safety reports only to the extent that a new appendix will be included to address the development and analysis of common mode events in 2017. The analysis of common mode events represents the single largest gap in the Pickering Safety Reports with respect to REGDOC-2.4.1." OPG is progressing this activity. (SF5-3)
GI-31-RS2	Prepare Implementation Plan update for REGDOC-2.4.1 including consideration of the impact of the extended operating period. OPG is progressing this activity. (SF5-4) (COP-21)
GI-31-AD1	Required system performance under accident conditions is addressed in the Pickering Safety Reports. Also, a full range of initiating events, including AOO-type sequences, is considered in the PSAs. However, AOOs have not been identified and analyzed in the current Pickering Safety Reports. Pickering has a comprehensive list of events (Initiating Events) defined for the safety analyses that are modelled in the PSA and the risk is acceptably low. Consideration of the identification and analysis of AOOs is addressed under the REGDOC-2.4.1 implementation plan which will be updated in accordance with the Licence Conditions Handbook and will identify any changes required to support the continued safe operation of Pickering NGS. These changes will be informed by the timeline of the Darlington REGDOC-2.4.1 Implementation Plan and the limited additional years of Pickering NGS operation. A practicable solution to addressing the AOOs requirements identified in the design-related code gaps, and implementing any enhancements within the time available during extended operation, is not readily evident. On this basis, and given the low safety significance (Safety Significance Level 3), this is assessed as an Acceptable Deviation. (SF1-8) (SF1-14) (SF1-15) (SF1-16) (SF1-18) (SF1-AG14)
GI-31-AD2	The analysis code ADDAM (Atmospheric Dispersion and Dose Analysis Method) is an Industry Standard Toolset code used, as required, for analysis updates that include atmospheric dispersion and dose calculations. ADDAM has been evaluated against the 2014 version of CSA N288.2 under COG Project WP 50109 [N-CORR-00531-06905, *REGDOC 3.1.1 Research and Development Annual Reporting*, June 16, 2015], outside of PSR2. The section by section review showed that no major modifications to the ADDAM 1.4.2 code, methodology or manuals would be required [COG report ISTO-15-5057, *Assessment of Impact of CSA N288.2-14 on ADDAM*, March 2017]. The ADDAM 1.4.2 code is being used in the update of the Pickering Safety Report Common Mode Events appendices, under the REGDOC-2.4.1 Implementation Plan. As the REGDOC-2.4.1 Implementation Plan does not identify other updates of the Pickering Safety Reports' analyses to address changes in N288.2-14, the existing Safety Report analyses related to atmospheric dispersion and dose calculations continue to support the safety case for Pickering. On this basis, and given the low safety significance (Safety Significance Level 3), this is assessed as an Acceptable Deviation. (SF5-6)
GI-31-NFA1	AI 201113-2297 is related to the modified 37-Element Fuel Bundle and was closed

SECTION 5 - GI-31 RESOLUTION PLAN	
	by the CNSC in April 2014 [NK38-CORR-00531-16762, e-Doc 4410455, *Action Item 201113-2297: Modified 37-Element Fuel Bundle CHF/PDO Test Results And CHF Correlation Development - New Action Item 2014-13-4926,* April 1, 2014]. The CNSC raised follow-up actions under AI 2014-13-4926 associated with assessment and quantification of Critical Heat Flux (CHF) data uncertainties and CHF/Critical Channel Power simulation uncertainties. These actions too were dispositioned by OPG in [NK38-CORR-00531-17038, *Darlington NGS - Modified 37-Element Fuel Bundle CHF/PDO Test Results and CHF Correlation Development - Action Item 2014-13-4926* October 30, 2014] and accepted by the CNSC in [NK38-CORR-00531-17353, e-Doc 4658016, *Darlington NGS: Modified 37-Element Fuel Bundle CHFIPDO Test Results and CHF Correlation Development - Closure of Action Item 2014-13-4926* March 26, 2015]. The relevant Action Item to Pickering is AI 2007-4-08 on 28-element CHF and it was closed on August 21, 2012 [NA44-CORR-00531-07002, e-Doc 3991677, *Pickering NGS-A -Safe Operation Following Findings From 28-Element Critical Heat Flux Tests -Action Item 2007-4-08 (RIB #2420),* August 21, 2012]. Follow-up Action Item 2012-OPG-3464 was also closed on February 13, 2013 [N-CORR-00531-06063, e-Doc 4054739, *Request for additional information on PHTS Aging Fuel Channel And Plant Thermalhydraulics and CCP uncertainty aspects of the new NOP Analysis Methodology – Closure of Action Item 2012-OPG-3464*, February 13, 2013]. There are no outstanding Action Items related to this issue. (COP-14)
GI-31-XRF-GI-44-AD8	Operator Action Time Credits. REGDOC-2.5.2 requirements for allowable times for operator action from the MCR or the field are more limiting than the corresponding requirements of REGDOC-2.4.1. Pickering A and B Safety Report credits for operator actions from the MCR and in the field are consistent with REGDOC-2.4.1 requirements of 15 and 30 minutes, respectively. The ability to execute required actions within these time limits has been demonstrated through decades of operation, through effective training and testing programs. The gap against the corresponding REGDOC 2.5.2 requirements is a low safety significance issue (Safety Significance Level 3) and has been addressed to the extent practicable. Therefore, it is assessed as an Acceptable Deviation. (SF5-AG1)

B.32. GI-32 Implementation of REGDOC-2.4.2 PSA Requirements

SECTION 1 - GI-32 GLOBAL ISSUE SUMMARY

The goal of GI-32, Implementation of REGDOC-2.4.2 PSA Requirements, is to complete the Implementation Strategy for CNSC Regulatory Document REGDOC-2.4.2, Probabilistic Safety Assessment, and to update the Strategy in the context of the extended operating period. This Global Issue comprises one proposed Resolution Statement addressing one SF6 code review Gap. Safety Significance Level 3 is assigned for this Global Issue based on probabilistic core damage frequency considerations.

The proposed Resolution Plan comprises a proposed Resolution Statement to complete the activities in the REGDOC-2.4.2 Implementation Strategy as identified in the Licence Conditions Handbook, and update the Strategy in the context of the extended operating period. Completion of the proposed Resolution Plan will support and strengthen Levels 2, 3, and 4 defence-in-depth for the extended operating period.

Safety Significance Level:	3	**Category:**	Programmatic, Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-32 ASSOCIATED GAPS

SF6-4	The REGDOC-2.4.2 Pickering Implementation Plan agreed to with the CNSC did not consider operation beyond 2020 and therefore, the review and update of the Implementation Plan in the context of operation of Pickering NGS beyond 2020 is required. Therefore, this has been identified as a PSR2 gap. ***Code Review CNSC REGDOC-2.4.2*** **Associated Resolutions:** GI-32-RS1

SECTION 3 - GI-32 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains one SF6 Gap related to the implementation of REGDOC-2.4.2.

This gap (SF6-4) is identified to consider the Implementation Strategy for REGDOC-2.4.2 documented in [P-CORR-00531-04557, *Pickering NGS-Request for Amendment to Pickering PROL 48.01/2018 to Implement New Regulatory Documents REGDOC-2.4.1 and REGDOC-2.4.2*, October 23, 2015], in the context of extended operation beyond 2020.

SECTION 4 - GI-32 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	N/A	N/A	**N/A**	3	N/A	N/A	N/A	N/A	N/A	N/A	**3**	**3**

Rationale:

This Global Issue is related to completion of the Implementation Strategy for REGDOC-2.4.2, and update of the Strategy with consideration of the extended operating period.

This Global Issue pertains specifically to the Pickering NGS Probabilistic Safety Assessment. Therefore, deterministic considerations, Defence in Depth (E1) and Safety Significance Levels (E2), are not applicable to this Global Issue.

With respect to probabilistic considerations, Safety Significance Level 3 is assigned the Core Damage Frequency (F1). The impact of resolving this Global Issue is not expected to cause a change in Core Damage Frequency greater than 10^{-6}/y. This corresponds to Safety Significance Level 3 in Table F1 of the PSR2 Basis Document. OPG has a comprehensive and robust Probabilistic Safety Assessment.

This Global Issue has no direct impact on the other probabilistic considerations, i.e., Defence in Depth (F2), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these other probabilistic considerations are not directly applicable to this issue.

In summary, the overall Safety Significance Level is 3. OPG is progressing this activity in support of extended operation at Pickering NGS.

SECTION 5 - GI-32 RESOLUTION PLAN

GI-32-RS1	Complete the activities in the REGDOC-2.4.2 Implementation Strategy, as identified in Section 5.1, Safety Analysis Program, of [P-CORR-00531-04886, CNSC Correspondence, e-Doc 5121102, *Pickering NGS: Licence Conditions Handbook, LCH-PNGS-R005*, November 10, 2016] and update the Strategy in the context of the additional operating period. OPG is progressing this activity in support of extended operation at Pickering NGS. (SF6-4)

B.33. GI-33 N285.0-12, General Requirements for Pressure-Retaining Systems and Components in CANDU Nuclear Power Plants

SECTION 1 - GI-33 GLOBAL ISSUE SUMMARY					
The goal of GI-33, N285.0-12 General Requirements for Pressure-Retaining Systems and Components in CANDU Nuclear Power Plants, is to ensure compliance with the requirements of CSA N285.0-12. This Global Issue comprises one Acceptable Deviation, one Cross Reference to GI-1, one Cross Reference to GI-2, one Cross Reference to GI-3, one Cross Reference to GI-4, and one Cross Reference to GI-5, which address two SF1 code review Gaps [CSA N285.0-12]. Safety Significance Level 3 is assigned to this Global Issue based on deterministic safety significance levels considerations. The cross references to GI-1, GI-2, GI-3 and GI-4 are to confirm that the allowable cycles for fatigue of the Class 1 major components will not be exceeded. The cross reference to GI-5 is to confirm the adequacy of the service limits assessments for Class 1 Piping after accounting for the impact of environmental factors. The Acceptable Deviation addresses Liquid Injection Shutdown System classification and it is based on a rationale that was accepted and a code classification concession that was granted by the CNSC. Completion of the proposed Resolution Plan for the cross references to other GIs will support and strengthen Level 1 defence-in-depth for the extended operating period.					
Safety Significance Level:	3	**Category:**	Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-33 ASSOCIATED GAPS	
SF1-1	Clause A.2.3.1 of CSA N285.0-06 identifies that for Shutdown Systems, pressure-retaining portions shall be classified as Class 1, except for three listed exceptions. It was identified during the Pickering B Integrated Safety Review (ISR) that a limited number of Liquid Injection Shutdown System (LISS) components, which should have been Class 1, were purchased and installed as Class 3. In follow-up, OPG proposed four actions to address the deficiency. When refurbishment was not pursued, a code classification concession was accepted for continued operations. This code classification concession and the four actions identified in the Pickering B ISR gap resolution need to be reconsidered in the context of operation of Pickering NGS beyond 2020. Therefore, this has been identified as a PSR2 gap. ***Code Review N285.0-12*** **Associated Resolutions:** GI-33-AD1
SF1-2	The Pickering A Return to Service review against CSA-N285.0-95 identified two Acceptable Deviations relating to Clause 7.0 requiring confirmation that the allowable cycles for fatigue would not be exceeded. For Pickering Units 1,4 and Units 5-8 operation beyond 2020, further confirmation is required that the allowable cycles for fatigue will continue to bound current

SECTION 2 - GI-33 ASSOCIATED GAPS

service limits for extended operation. Therefore, this has been identified as a PSR2 gap.

Code Review N285.0-12

Associated Resolutions: GI-1-RS3, GI-2-RS1, GI-3-RS1, GI-4-RS1, GI-5-RS1

SECTION 3 - GI-33 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains two SF1 Gaps related to CSA N285.0-12.

Compliance with CSA N285.0-08 (including Updates No. 1 and No. 2) is currently a licence requirement for Pickering NGS (per PROL 48.03/2018) as indicated in Section 6.2 and Appendix C.1 of the R05 Pickering Licence Conditions Handbook. Two gaps were identified: one is related to LISS component classification and the other gap is related to a required confirmation that the allowable cycles for fatigue will continue to bound current service limits for the extended operating period.

The service limits assessment requirement is limited to Nuclear Code Class 1 components, as a requirement under the current ASME Boiler and Pressure Vessel code [NK30-CORR-00531-06324, e-Doc 3947907, *Pickering NGS-B - CNSC Staff Assessment Of OPG's 2011 Continued Operations Plan (action Item 2010-8-05 (2461)) and path forward*, June 19, 2012, Attachment 1 – Part B (Table B-1), item 2.2.8].

For the Major Components, the OPG Life Cycle Management Plans (LCMPs) include confirmation that the allowable cycles for fatigue will continue to bound current service limits. This is complete to 2022 and 2024 for Pickering 1,4 and 5-8 Major Components respectively, and is addressed in GI-1, GI-2, GI-3 and GI-4.

For all other Code Class 1 components and piping, the confirmation that the allowable cycles for fatigue will continue to bound current service limits for the extended operating period is complete, and is addressed in GI-5. The activity to confirm the adequacy of the Class 1 piping service limits assessment after accounting for impact of environmental factors is also addressed in GI-5.

SECTION 4 - GI-33 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	N/A	3	**3**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**3**

Rationale:

This Global Issue is related to a code classification concession for Liquid Injection Shutdown System components, and confirmation that the allowable cycles for fatigue bound the service limits for extended operation for Nuclear Code Class I components. The Safety Significance Level of the LISS requirement is assessed in this Global Issue. The requirements for the other components (e.g., Fuel Channels) are cross referenced to proposed Resolution Statements in GI-1, GI-2, GI-3, GI-4 and GI-5.

Regarding deterministic considerations, this Global Issue is not directly applicable to Defence in Depth (E1). Safety Significance Levels (E2) is assigned Safety Significance Level 3 on the basis that the issue is not significant. The Liquid Injection Shutdown System deviation from Class 1 requirements was previously assessed to be acceptable and accepted by the CNSC. Hence, the overall Safety Significance Level of 3 for deterministic considerations is dictated by the E2 categorization.

This Global Issue has no direct impact on the probabilistic considerations, i.e., Core Damage Frequency (F1), Defence in Depth (F2), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, the probabilistic considerations are not directly applicable to this issue.

In summary, the overall Safety Significance Level is 3 with respect to the LISS components.

SECTION 5 - GI-33 RESOLUTION PLAN

GI-33-AD1	A limited number of LISS components that should have been code Class 1 were purchased and installed as code Class 3. However, a rationale was accepted and a code classification concession was granted by the CNSC to allow the system to remain as-is for the legacy modifications. Further installations would be done using code Class 1 materials [NK30-CORR-00531-02663, OPG Correspondence, *Pickering NGS 'B' Units 5-8 Liquid Injection Shutdown System (34700) Request for Code Classification Approval*, December 13, 2004] and [NK30-CORR-00531-03047, CNSC Correspondence File: 26-1-8-3-0, *Pickering NGS-B Code*

SECTION 5 - GI-33 RESOLUTION PLAN	
	Classification Approval – Legacy Modifications to Liquid Injection Shutdown System (USI 34700), Units 5-8, February 11, 2005]. In NK30-CORR-00531-02663, OPG provided rationale to show that consequences following any failure of Class 3 or Class 6 portions of the systems continue to satisfy the requirements of N285.0. On this basis, this issue is low safety significance (Safety Significance Level 3) and is being managed to the extent practicable. Therefore it is assessed as an Acceptable Deviation. (SF1-1)
GI-33-XRF-GI-1-RS3	Update the Fuel Channels LCMP [N-PLAN-01060-10002-R017, OPG Plan, *Fuel Channels Life-Cycle Management Plan*, October 30, 2016] for Pickering Units 1,4 for the extended operating period. (SF1-2)
GI-33-XRF-GI-2-RS1	Update the Feeders LCMP [N-PLAN-01060-10001-R018, OPG Plan, *Feeders Life Cycle Management Plan*, October 31, 2016] for Pickering Units 1,4 for the extended operating period. (SF1-2)
GI-33-XRF-GI-3-RS1	Update the Steam Generators LCMP [N-PLAN-33110-10009-R007, OPG Plan, *Steam Generators Life Cycle Management Plan*, October 24, 2016] for Pickering Units 1,4 for the extended operating period. (SF1-2)
GI-33-XRF-GI-4-RS1	Update the Reactor Components and Structures LCMP [N-PLAN-01060-10003-R014, OPG Plan, *Reactor Components and Structures Life Cycle Management Plan*, October 30, 2016], based on updated Fitness for Service assessment and an updated Technical Basis Document [N-PLAN-01060-10008 R00, *Reactor Components & Structures Life Cycle Management Plan: Technical Basis Document*, June 25, 2010] for Pickering Units 1,4 for the extended operating period. (SF1-2)
GI-33-XRF-GI-5-RS1	Confirm the adequacy of the service limits assessments for Nuclear Class 1 Piping after accounting for impact of environmental factors (for example: irradiation, temperature, humidity). (SF1-2)

B.34. GI-34 CSA N290.1-13 - Requirements for the Shutdown Systems

SECTION 1 - GI-34 GLOBAL ISSUE SUMMARY					
The goal of GI-34, CSA N290.1-13- Requirements for the Shutdown Systems, is to demonstrate an appropriate degree of conformance with the requirements of CSA N290.1-13. This Global Issue comprises one Acceptable Deviation addressing one SF1 code review Gap related to remote tripping and monitoring capability. Safety Significance Level 3 is assigned for this Global Issue based on deterministic defence-in-depth considerations. The proposed Resolution Plan comprises an Acceptable Deviation based on the low safety significance level and the availability of dedicated remote tripping and monitoring for Pickering 1,4 SDSE at the Instrument Rooms and for Units 5-8 SDS2 at the Unit Emergency Control Centres. This arrangement meets the intent of the requirements of CSA N290.1-13 to the extent practicable.					
Safety Significance Level:	3	**Category:**	Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-34 ASSOCIATED GAPS	
SF1-10	Clause 4.1.8.2 of CSA N290.1-13 is for a new plant and requires remote tripping and monitoring capability for both Shutdown Systems. Pickering Units 1,4 only have one Shutdown System with tripping capability from separate logic (SDSA and SDSE). Remote tripping capability is available for Pickering 5-8 SDS2 and Pickering 1,4 SDSE. However, Pickering Units 5-8 and 1,4 do not have remote tripping and monitoring capability for SDS1 or SDSA respectively. Therefore, this has been identified as a PSR2 gap. ***Code Review N290.1-13*** **Associated Resolutions:** GI-34-AD1

SECTION 3 - GI-34 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains one SF1 gap related to CSA N290.1-13. Compliance with N290.1 is not currently a licence requirement for Pickering NGS (PROL 48.03/2018) and is not referenced in the Pickering Licence Conditions Handbook. The gap (SF1-10) is related to Clause 4.1.8.2 of CSA N290.1-13 which requires remote tripping and monitoring capability to be available for both Shutdown Systems in a secondary control room. Both Pickering 5-8 and 1,4 have remote tripping capability for SDS2 and SDSE, respectively. Pickering 5-8 has SDS2 tripping capability in the Unit Emergency Control Centres (UECCs). Pickering 1,4 has remote SDSE tripping capability in the SDSE Instrument Room. Neither SDSA at Pickering 1,4

SECTION 3 - GI-34 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

nor SDS1 at Pickering 5-8 have remote tripping and monitoring capability.

SECTION 4 - GI-34 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	3	N/A	**3**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**3**

Rationale:

This Global Issue is related to remote tripping and monitoring capability for both Shutdown Systems.

Regarding deterministic considerations, this Global Issue is assigned a Safety Significance Level 3 for Defence in Depth (E1), since the issue is related to, but does not impair, shutdown capability (row 3 of Table E1 in the PSR2 Basis Document). There is dedicated remote tripping and monitoring capability at Pickering 1,4 with SDSE and at Pickering 5-8 with SDS2. Safety Significance Levels (E2) is not directly applicable since this Global Issue can have a direct impact on nuclear safety, whereas E2 primarily relates to issues that are indirectly related to nuclear safety. Hence, the overall safety Significance Level of 3 for deterministic considerations is dictated by the E1 categorization.

This Global Issue has no direct impact on the probabilistic considerations, i.e., Core Damage Frequency (F1), Defence in Depth (F2), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, the probabilistic considerations are not directly applicable to this issue.

In summary, the overall Safety Significance Level is 3.

SECTION 5 - GI-34 RESOLUTION PLAN

GI-34-AD1	There is dedicated remote tripping and monitoring capability at Pickering 1,4 for SDSE in the SDSE Instrument Rooms [NA44-SR-01320-00001-R016, *Pickering A Safety Report*, July 20, 2017] and at Pickering 5-8 for SDS2 in the Unit Emergency Control Centres [NK30-SR-01320-00002-R004, *Pickering B Safety Report – Part*

SECTION 5 - GI-34 RESOLUTION PLAN	
	2, October 10, 2012], and this meets the CSA N290.1 intent and requirements to the extent practicable. In addition, the failure to shutdown probability, as demonstrated in the PSAs, is very low [P-REP-03611-00006-R000, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014]. On this basis, and as per the low safety significance level (Safety Significance Level 3), this issue is assessed as an Acceptable Deviation. (SF1-10)

B.35. GI-35 Human Factors Issues

SECTION 1 - GI-35 GLOBAL ISSUE SUMMARY					
The goal of GI-35, Human Factors Issues, is to demonstrate an appropriate degree of conformance with specific Human Factors requirements of CSA N290.0-11 General requirements for safety systems of nuclear power plants. This Global Issue includes one SF1 code review Gap that is assessed to be an Acceptable Deviation and one SF1 Additional Gap related to NUREG-0700 that is assessed as No Further Action. Safety Significance Level 4 is assigned for this Global Issue based on deterministic defence-in-depth considerations. The SF1 Gap is related to Human Factors Engineering (HFE) activities not being formally documented when the Main Control Rooms were originally designed and constructed and is considered an Acceptable Deviation based on the extensive operating experience and the established processes and instructions to ensure that human-system interface elements for a modification are addressed.					
Safety Significance Level:	4	**Category:**	Programmatic	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-35 ASSOCIATED GAPS	
SF1-7	The Darlington Integrated Safety Review (ISR) identified a gap against Clause 4.14.10 of N290.0-11 as a result of the lack of design standards related to Human Factors Engineering (HFE) or HFE activities being formally documented when the Main Control Rooms were originally designed and constructed. Pickering NGS has many years of successful Special Safety System (SSS) operation and the absence of formal HFE in the original design is not expected to have any nuclear safety significance relating to SSSs. However, the Darlington gap is also applicable to Pickering NGS and is therefore identified as a PSR2 gap. ***Code Review N290.0-11*** **Associated Resolutions:** GI-35-AD1
SF1-AG7	An SF1 Gap related to a review of Pickering B against NUREG-0700 was identified in [P-CORR-00531-05107, e-Doc 5305945, July 26, 2017]. **Associated Resolutions:** GI-35-NFA1

SECTION 3 - GI-35 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains two Gaps, an SF1 report Gap (SF1-7) and an SF1 Additional Gap (SF1-AG7). SF1-7 is against Clause 4.14.10 of N290.0-11 as a result of minimal design standards being available related to Human Factors Engineering (HFE) or HFE activities not being formally documented when the Main Control Rooms were originally designed and constructed. SF1-AG7 is related to consideration of [NUREG-0700, Rev. 2, *Human-System Interface Design Review Guidelines*, May

SECTION 3 - GI-35 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

2002] and [NUREG-0711, Rev. 3, *Human Factors Engineering Program Review Model*, November 2012] in PSR2 reviews.

When the Main Control Rooms were designed, Ontario Hydro employed electrical standards that included indicating lamp conventions, handswitch conventions, and labeling conventions. For design modifications that require an HFE plan, the plans prepared by OPG meet the requirements of CNSC G-276 [G-276, *Human Factors Engineering Program Plans*, June 2003] and CNSC G-278 [G-278, *Human Factors Verification and Validation Plans*, June 2003].

SECTION 4 - GI-35 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	4	N/A	**4**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**4**

Rationale:

This Global Issue is related to minimal design standards being available for Human Factors Engineering activities, or these activities not being formally documented, when the Main Control Rooms were originally designed and constructed. As discussed in Section 5 of this Global Issue, the original design phase of Pickering NGS recognized the need for focus on the operator interfaces in the control centres, and the related human-systems interfaces. The Pickering units as a result have decades of safe operation and operating experience with monitoring, operation, testing, maintenance and training (including simulators).

Regarding deterministic considerations, this Global Issue is assigned Safety significance Level 4 for Defence in Depth (E1). This is because this issue is not significant by itself and it has no impact on the level of operational performance and safety culture. Safety Significance Levels (E2) is not directly applicable since this Global Issue can have a direct impact on nuclear safety, whereas E2 primarily relates to issues that are indirectly related to nuclear safety. Hence, the overall safety Significance Level of 4 for deterministic considerations is dictated by the E1 categorization.

This Global Issue has no direct impact on the probabilistic considerations, i.e., Core Damage Frequency (F1), Defence in Depth (F2), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore,

SECTION 4 - GI-35 PRIORITY DETERMINATION
the probabilistic considerations are not directly applicable to this issue. In summary, the overall Safety Significance Level is 4.

SECTION 5 - GI-35 RESOLUTION PLAN	
GI-35-AD1	The original design phase of Pickering NGS recognized the need for focus on the operator interfaces in the control centres and on recognition of the integrated whole of the control centre and the related human-systems interfaces. The Pickering units as a result have decades of safe operation and operating experience with monitoring, operation, testing, maintenance and training (including simulators). With regards to plant modifications, all plant modifications are required to be completed in compliance with N-PROG-MP-0001 [N-PROG-MP-0001 R015, OPG Nuclear Program, *Engineering Change Control*, May 12, 2017], which includes the requirements for Human Factors and Ergonomics to be considered in design. If the modification is judged to have an HFE impact, a Human Factors Engineering Specialist must concur with the Human Factors Level of Activity. The modification may require the preparation of the Human Factors Engineering Plan or the Human Factors Worksheet. These instructions and processes ensure that the human-system interface elements for the modification are addressed. The technical, design and operator reviews, during and following the design process and via the Availability for Service (AFS) process, ensure the usability requirements will be achieved. Based on the extensive operating experience and modifications processes, there is no justification for revisiting the overall Main Control Room design from a Human Factors perspective. On this basis, and as per the very low safety significance (Safety Significance Level 4), this is assessed as an Acceptable Deviation. (SF1-7)
GI-35-NFA1	The review task assessment in the Safety Factor Report [P-REP-03680-00008 R000, *Pickering NGS PSR2 Safety Factor 1 Report: Plant Design*, March 3, 2017] confirmed that Human Factors Engineering Program Plans prepared by OPG meet the requirements of CNSC G-276 [G-276, *Human Factors Engineering Program Plans*, June 2003] and CNSC G-278 [G-278, *Human Factors Verification and Validation Plans*, June 2003] and the applicable elements from [NUREG-0711, Rev. 3, *Human Factors Engineering Program Review Model*, November 2012]. Per OPG governance, specifically OPG Manual [N-MAN-06700-10002, *Guide for OPG Human Factors Engineering Process*, December 18 2015], the Human Factors Engineering Program Plans are expected to meet the intent of NUREG-0711. With respect to human-system interface in design, the Pickering units have years of safe operating experience with special safety system monitoring, operation (including testing), maintenance and training (including simulator). Improvements based on operation and maintenance experience have also been incorporated into processes and the design to improve the human-machine interface. In addition, training and qualification processes (and certification processes for control room staff) for Operations positions ensure that the staff are competent to carry out

SECTION 5 - GI-35 RESOLUTION PLAN	
	functions assigned to them. Any potentially significant human interaction deficiencies due to the design would be identified during these activities and be addressed. Hence, the extent of application of human factors engineering in the original design is not expected to have an impact on nuclear safety relating to the SSCs. Therefore, a review of the design of human-system interfaces to assess the extent to which Pickering NGS meets [NUREG-0700, Rev. 2, *Human-System Interface Design Review Guidelines*, May 2002] is not considered necessary. A gap analysis against mandatory requirements of CSA N290.12-14, Human Factors in Design for Nuclear Power Plants, was performed for PSR2 in [P-REP-03680-00021, Pickering PSR2 law, Regulation, Code and Standard Reviews Associated with Safety Factors 8, 10, 12, 13, and 14] and found only minor issues that do not have a nuclear safety impact, and there are no PSR2 gaps. Also, versions of CSA N290.0, General Requirements for Safety Systems of Nuclear Power Plants, subject to previous PSR1 reviews, as well as their applicability to Pickering PSR2, are assessed in [P-REP-03680-00029, Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 1, 5, 6, and 7], and a gap was identified against clause 4.14.10 of CSA N290.0 on human-machine interface requirements. The gap (SF1-7) from CSA N290.0 is assessed as an Acceptable Deviation under GI-35. Therefore, based on the years of safe operation, incorporation of OPEX into Pickering NGS modifications, procedures, training and the results of assessments of CSA N290.12-14 and CSA N290.0, Pickering NGS can maintain its safe operation for the extended period, and a review of NUREG-0700 and NUREG-0711 is not considered necessary. No further action is required. (SF1-AG7)

B.36. GI-36 CSA N290.2 - Requirements for Emergency Core Cooling Systems

SECTION 1 - GI-36 GLOBAL ISSUE SUMMARY					
The goal of GI-36, CSA N290.2- Requirements for Emergency Core Cooling Systems, is to demonstrate an appropriate degree of conformance with the requirements of this standard. This Global Issue comprises two Acceptable Deviations addressing two SF1 code review Gaps. Safety Significance Level 3 is assigned for this Global Issue based on the deterministic and probabilistic defence-in-depth considerations. The proposed Resolution Plan comprises two Acceptable Deviations, each addressing one Gap. The first Acceptable Deviation addresses the Gap related to the requirement to assess ECI effectiveness based on the least effective of the Shutdown Systems. The Pickering 1,4 Shutdown System arrangement has previously been accepted by the CNSC and the ECI capability is assessed using the available SDS and hence this meets the CSA N290.2 requirement to the extent practicable. The second Gap relates to instrumentation to monitor emergency cooling debris strainer effectiveness post-accident. This Gap is assessed as an Acceptable Deviation because monitoring ECI recovery pump performance and Reactor Building water level for any adverse trend in performance expected to be caused by debris loading meets the intent of this requirement.					
Safety Significance Level:	3	**Category:**	Engineering	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-36 ASSOCIATED GAPS	
SF1-11	Clause 5.2.1.2 of CSA N290.2-11 requires that Emergency Coolant Injection System (ECIS) design requirements be based on the assumption that the least effective of the Shutdown Systems has operated successfully. The Pickering Units 5-8 Safety Report analysis does address this requirement and the requirement is also contained in the Pickering Units 5-8 Design Requirements. However, this requirement cannot be met for Pickering Units 1,4 since there is only one Shutdown System (albeit with tripping capability from separate SDSA and SDSE logic). Therefore, this has been identified as a PSR2 gap. ***Code Review N290.2-11*** **Associated Resolutions:** GI-36-AD1
SF1-12	Clause 5.14.11 of CSA N290.2-11 requires instrumentation to be available to monitor post-accident effectiveness and to determine the extent of plugging of Emergency Coolant Injection System (ECIS) debris interceptors (strainers). While relative health of a strainer can be inferred by a combination of ECIS recovery pump performance and Reactor Building water level, there is no direct correlation between these conditions and debris loading available. Therefore, this has been identified as a PSR2 gap (which is applicable to both Pickering Units 5-8 and 1,4). ***Code Review N290.2-11***

SECTION 2 - GI-36 ASSOCIATED GAPS

Associated Resolutions: GI-36-AD2

SECTION 3 - GI-36 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains two SF1 Gaps related to CSA N290.2.

CSA N290.2 is identified in Appendix E.1 of the R05 Pickering Licence Conditions Handbook as "Guidance or Criteria".

SECTION 4 - GI-36 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	3	N/A	**3**	4	3	N/A	N/A	N/A	N/A	N/A	**3**	**3**

Rationale:

This Global Issue includes two gaps, one related to Pickering 1,4 ECI System capability with respect to Shutdown System operation and the other gap is related to monitoring of ECI System debris strainer effectiveness.

Regarding deterministic considerations, this Global Issue is assigned Safety Significance Level 3 for Defence in Depth (E1) on the basis that the issue is related to but does not impact ECI Injection System capability (row 3 of Table E1 in the PSR2 Basis Document). This is because for the first gap, although there is only one Shutdown System on Pickering 1,4, the tripping capability from separate SDSA and SDSE logic exists. For the second gap, the intent of the requirement is met by monitoring ECI recovery pump performance and Reactor Building water level. Safety Significance Levels (E2) is not directly applicable since this Global Issue can have a direct impact on nuclear safety, whereas E2 primarily relates to issues that are indirectly related to nuclear safety. Hence, the overall Safety Significance Level of 3 for deterministic considerations is dictated by the E1 categorization.

Regarding probabilistic considerations, the issue has Safety Significance Level 3 for Reactor Safety - Defence in Depth (F2). This is because the issue is related to the reliability of ECI System

SECTION 4 - GI-36 PRIORITY DETERMINATION

operation which is required for events with initiating frequency on the order of 10^{-3}/y or less. For Reactor Safety – Core Damage Frequency (F1), the issue has Safety Significance Level 4 since any impact on Core Damage Frequency is expected to be insignificant (less than 10^{-7}/y).

This Global Issue has no direct impact on the other probabilistic considerations, i.e., Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these probabilistic considerations are not applicable, and the overall Safety Significance Level of 3 for probabilistic considerations is dictated by the F2 categorization.

In summary, the overall Safety Significance Level is 3. The issue is mitigated by alternative design features.

SECTION 5 - GI-36 RESOLUTION PLAN

GI-36-AD1	This issue is related to ECIS capability with respect to Shutdown System operation. The design of the Pickering 1,4 Shutdown System has previously been accepted by CNSC and the ECIS capability is assessed using the available SDS and hence this meets the CSA N290.2 requirement to the extent practicable. The Pickering 1,4 ECI System reliability meets the licensing target, as demonstrated in [NA44-REP-09051.1-00014, R000, *2014 Annual Reliability Report – Pickering Units 1 & 4*, March 10, 2015]. On this basis, and as per the low safety significance of this issue (Safety Significance Level 3), this is assessed as an Acceptable Deviation. (SF1-11)
GI-36-AD2	This issue is related to monitoring of ECIS debris strainer effectiveness. The detailed assessment of the potential sources of strainer debris and contaminants for Pickering 5-8 [NK30-CORR-00531-05194 R001, *Pickering B – Generic Action Item 06G01 Emergency Core Cooling System Strainer Deposits – Status Update and Request for Closure*, June 30, 2009] demonstrated sufficient margin to ensure post-accident ECI recovery strainer effectiveness. The issues identified in the Pickering 1,4 assessment [NA44-CORR-00531-06062, *GAI 06G01: Emergency Core Cooling System Strainer Deposits – Status Update*, June 30, 2009] resulted in the installation of new strainer modules in Units 1 and 4. Since Pickering 1,4 and 5-8 comply with the requirements for new plant debris interceptors, with the exception of clause 5.14.11, the benefit of developing and implementing new instrumentation for post-accident effectiveness is assessed to be small. This is because the intent of the requirement is met by monitoring ECI recovery pump performance and Reactor Building water level for any adverse trend in performance expected to be caused by debris loading. Additional mitigating factors include (a) the demonstrated margin that ensures post-accident effectiveness of the ECI recovery phase with the installed strainer modules, (b) the low contribution of ECIS recovery strainer plugging to the PSA results [NA44-CORR-33350-0265268-R000, *Pickering A Risk Assessment ECI Strainer Plugging Following a Large LOCA*, September 23, 2008], and (c) mandatory inspections to ensure the ECI recovery flowpath is free from debris prior to restart of a Pickering 5-8 or Pickering 1,4 unit following a maintenance outage [NK30-SRS-E-082-R004, *ECI Recovery Flowpath Inspection*, March 27, 2014], [NA44-SRS-E-026-U14-

SECTION 5 - GI-36 RESOLUTION PLAN	
	R019, *ECI Recovery Flowpath Inspection*, February 21, 2017]. Given the low safety significance (Safety Significance Level 3), this is assessed as an Acceptable Deviation. (SF1-12)

B.37. GI-37 N290.3-11 - Requirements for Containment System

SECTION 1 - GI-37 GLOBAL ISSUE SUMMARY					
The goal of GI-37, N290.3-11 Requirements for Containment System, is to demonstrate an appropriate degree of conformance with the requirements of this standard. This Global Issue comprises one Cross Reference to GI-40 addressing one SF1 code review Gap and one SF1 Additional Gap. Safety Significance Level 3 is assigned for this Global Issue based on deterministic and probabilistic defence-in-depth considerations. Completion of the cross referenced proposed Resolution Statement under GI-40 (completion of the installation of Phase 2 Emergency Mitigating Equipment) will support and strengthen defence-in-depth Levels 3 and 4 for the extended operating period.					
Safety Significance Level:	3	**Category:**	Engineering	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-37 ASSOCIATED GAPS	
SF1-13	Per CSA N290.3-11, a Containment Energy Management System (EMS) and Radionuclide Management System (RMS) are required to protect Containment and minimize radiological releases for Beyond Design Basis Accidents (BDBAs). The Pickering EMS and RMS use the Filtered Air Discharge System (FADS) and Reactor Building Air Cooling Units (ACUs). Enhancements to the AC power supplies to these systems and related loads are being provided by Phase 2 Emergency Mitigating Equipment (EME), which is not yet fully implemented. This PSR2 gap has been identified to track the implementation of Phase 2 EME such that it can be used to support the EMS and RMS. ***Code Review N290.3-11*** **Associated Resolutions:** GI-40-RS1
SF1-AG15	An SF1 Gap related to conformance with specific clauses of CSA N290.3 on Containment behaviour during a BDBA, and the installation of a filtered venting system for extended operation to protect containment and prevent uncontrolled large releases following a BDBA, was identified in [P-CORR-00531-05107, e-Doc 5305945, July 26, 2017]. The associated resolution addresses Item (a) of the reference. Item (b) is being addressed as described in [P-CORR-00531-05132, *Pickering Periodic Safety Review 2- Process for Addressing CNSC Identified Additional Gaps*, September 18, 2017]. **Associated Resolutions:** GI-40-RS1

SECTION 3 - GI-37 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains one SF1 code review gap and one SF1 Additional Gap related to CSA N290.3-11.

CSA N290.3 is identified in Appendix E.1 of the R05 Pickering Licence Conditions Handbook as “Guidance or Criteria”. Two gaps were identified related to completion of EME Phase 2.

The high-level intents of a Containment Energy Management System (EMS) and a Radionuclide Management System (RMS) are addressed in Pickering 5-8 by the completion of EME Phase 2, which includes supplying cooling water, and power supplies to essential loads via EME generators, to allow for operation of Air Cooling Units and Hydrogen Igniters. For Pickering 1,4, the additional design, operational and/or analytical enhancements to improve Severe Core Damage Frequency and Large Release Frequency resulting from GI-27-RS2 will supplement the enhancements achieved by the completion of the EME Phase 2 project. These enhancements will further complement the existing Pickering design provisions for maintaining containment integrity.

SECTION 4 - GI-37 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	3	N/A	**3**	N/A	3	4	N/A	N/A	N/A	N/A	**3**	**3**

Rationale:

This Global Issue is related to CSA N290.3-11, Requirements for the Containment System of Nuclear Power Plants. A number of initiatives related to BDBAs, including completion of Phase 2 of the Emergency Mitigating Equipment project, are proposed.

Regarding deterministic considerations, this Global Issue is assigned Safety Significance Level 3 for Defence in Depth (E1) on the basis that the issue is related to minimizing radiological releases for BDBAs (row 3 of Table E1 in the PSR2 Basis Document). Safety Significance Levels (E2) is not directly applicable since this Global Issue can have a direct impact on nuclear safety, whereas E2 primarily relates to issues that are indirectly related to nuclear safety. Hence, the overall Safety Significance Level of 3 for deterministic considerations is dictated by the E1 categorization.

Regarding probabilistic considerations, the issue has Safety Significance Level 3 for Reactor

SECTION 4 - GI-37 PRIORITY DETERMINATION
Safety - Defence in Depth (F2). This is because the initiatives are related to BDBAs. Therefore, the fourth column of the top row of Table F2 of the PSR2 Basis Document is applicable, and the corresponding Safety Significance Level is 3 because the frequency range for BDBAs is less than 10^{-5}/y. Public Radiation Safety (F3) is assigned Safety Significance Level 4 on the basis that the public individual dose could be reduced by ~0.1 mSv for some events with initiating frequency ~ 10^{-5}/y. This Global Issue has no direct impact on the other probabilistic considerations, i.e., Core Damage Frequency (F1) (because Containment does not affect Core Damage Frequency), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these probabilistic considerations are not applicable, and the overall Safety Significance Level of 3 for probabilistic considerations is dictated by the F2 categorization. In summary, the overall Safety Significance Level is 3. OPG is actively progressing Phase 2 of the Emergency Mitigating Equipment project in support of extended operation at Pickering NGS.

SECTION 5 - GI-37 RESOLUTION PLAN	
GI-37-XRF-GI-40-RS1	Complete the planned Phase 2 EME implementation. This includes supplying cooling water, and power to essential loads via EME generators, to allow for operation of Air Cooling Units (ACUs) and Hydrogen Igniters [P-CORR-00531-04945, OPG Correspondence, *Pickering NGS – CNSC Action Item 2016-48-7470 Status Update on Emergency Mitigating Equipment and Telecommunications Projects*, February 16, 2017]. OPG is actively progressing this work in support of extended operation at Pickering NGS. (SF1-13) (SF1-AG15 Item (a))

B.38. GI-38 CSA N290.11 - Requirements for Reactor Heat Sinks

SECTION 1 - GI-38 GLOBAL ISSUE SUMMARY					
The goal of GI-38, CSA N290.11- Requirements for Reactor Heat Sinks, is to demonstrate an appropriate degree of conformance with the requirements of this standard. This Global Issue includes one SF1 code review Gap related to outage heat sink reliability requirements that is assessed as an Acceptable Deviation and one SF1 Additional Gap related to assessment of manual operator actions for outage heat sinks that is assessed as requiring No Further Action. Safety Significance Level 4 is assigned for this Global Issue based on deterministic and probabilistic defence-in-depth considerations and probabilistic core damage frequency considerations. The proposed Resolution Plan comprises an Acceptable Deviation based on the reliability of all outage heat sinks being integrated and assessed as part of the Outage Probabilistic Safety Assessments. Therefore, the reactor safety impact of not having individual heat sink design reliability requirements is not significant. The proposed Resolution Plan also comprises an item which requires No Further Action since the information and main assumptions regarding operator actions for heat sink operation, maintenance and recall are documented.					
Safety Significance Level:	4	**Category:**	Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-38 ASSOCIATED GAPS	
SF1-17	Clause 5.6.1 of CSA N290.11-13 requires design reliability to be established for outage heat sinks. Although some emergency heat sinks (e.g., Emergency Boiler Water Supply and Emergency Water Supply) have design reliability requirements, design reliability requirements have not been established for all normal and back-up heat sinks used at Pickering. Reliability of all outage heat sinks (including those without explicit targets) is managed under the Risk & Reliability Program (both through unavailability models as well as through Probabilistic Safety Assessment), hence reactor safety impact is assessed and monitored. However, there is a PSR2 gap with respect to establishment of design reliability requirements for Pickering Units 1,4 and 5-8 outage heat sinks. ***Code Review N290.11-13*** **Associated Resolutions:** GI-38-AD1
SF1-AG20	An SF1 Gap related to the main assumptions and assessment methodology used when postulating a delay or error for manual actions to recall a heat sink during outage and maintenance was identified in [P-CORR-00531-05107, e-Doc 5305945, July 26, 2017]. **Associated Resolutions:** GI-38-NFA1

SECTION 3 – GI-38 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains two Gaps: one SF1 Gap on the CSA N290.11-13 requirement for specifying reliability targets for outage heat sinks, and one Additional Gap on the assessment methodology when postulating a delay or error for manual actions during outage and maintenance.

SECTION 4 – GI-38 PRIORITY DETERMINATION

	Deterministic Considerations			Probabilistic Considerations								
Safety Significance of Global Issue	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	**Overall Safety Significance Level**
	4	N/A	**4**	4	4	N/A	N/A	N/A	N/A	N/A	**4**	**4**

<u>Rationale:</u>

This Global Issue is related to the CSA N290.11 requirement on specifying reliability targets for outage heat sinks. As discussed in Section 5 of this Global Issue, the reliability of all outage heat sinks is assessed as part of the Outage Probabilistic Safety Assessments. Therefore, the reactor safety impact of not having explicit heat sink design reliability is assessed as not being a significant issue.

Regarding deterministic considerations, this Global Issue is assigned Safety Significance Level 4 for Defence in Depth (E1). This is because this issue is not significant by itself and it has no impact on the level of operational performance. Safety Significance Levels (E2) is not directly applicable since this Global Issue can have a direct impact on nuclear safety, whereas E2 primarily relates to issues that are indirectly related to nuclear safety. Hence, the overall Safety Significance Level of 4 for deterministic considerations is dictated by the E1 categorization.

Safety Significance Level 4 is assigned to probabilistic considerations Core Damage Frequency (F1) and Defence in Depth (F2). This is because, as mentioned above, Pickering takes an integrated approach to outage heat sink management and therefore, the impact on these considerations is not significant. This Global Issue has no direct impact on the other probabilistic considerations, i.e., Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). The overall Safety Significance Level of 4 for probabilistic considerations is dictated by the F1 and F2 categorizations.

In summary, the overall Safety Significance Level is 4.

SECTION 5 – GI-38 RESOLUTION PLAN	
GI-38-AD1	Unavailability targets for the shutdown cooling systems and for other systems/components that are part of the various heat sinks (e.g., EBWS and HT P&IC) are established and reported annually in the annual risk and reliability report [P-REP-09051.1-00016-R000, OPG Report, *Pickering NGS – 2016 Annual Risk and Reliability Report*, March 31, 2017]. The reliability of all outage heat sinks is integrated and assessed as part of the Outage Probabilistic Safety Assessments [P-REP-03611-00006-R000, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014]. Therefore the reactor safety impact of not having explicit heat sink design reliability is assessed, monitored and is not a significant issue. Due to the very low safety significance (Safety Significance Level 4), this is assessed as an Acceptable Deviation. (SF1-17)
GI-38-NFA1	Governance is in place that defines nuclear safety principles and requirements for management of reactor heat sinks [N-STD-OP-0025-R003, *Heat Sink Management,* October 23, 2014]. It ensures that alternate heat sinks are provided as defence-in-depth against loss of heat sink events by requiring availability of a back-up heat sink, for more probable failures of the primary heat sink, in order to prevent total loss of process heat sinks and emergency heat sinks, to mitigate consequences of a loss of process heat sink accident considered as part of the design or licensing basis (i.e., lower probability events). The outage heat sinks are managed according to the Shutdown Heat Sink operating manuals ([NK30-OM-5-04300, *Shutdown Heat Sinks Unit 5-8],* [NA44-OM-14-04300, *Shutdown Heat Sinks Units 1, 4*]) where each heat sink configuration is specified with the required operator actions, and the time allowed for each configuration is managed throughout the outage with the preparation of the daily Shutdown Heat Sinks Check Sheet ([P-FORM-10216-R018, *Shutdown Heat Sink Check Sheet PNGS-B*, May 1, 2017], [P-FORM-10308-R020, *Shutdown Heat Sinks Checksheet*, May 26, 2017]) which specifies the primary, backup and emergency heat sinks and the available time for operators to take action. The assessment for delay or error in manual actions and risk evaluation of human error involves use of the Outage Probabilistic Safety Assessments [P-REP-03611-00006-R000, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014] based on the details of the heat sink operating procedures. The human reliability methodology applied in the Outage PSA is documented in the OPG Outage PSA and At-Power PSA Guides ([N-GUID-03611-10001 Vol 4 R01, OPG Outage Probabilistic Risk Assessment (PRA) Guide – Level 1, July 9, 2010], [N-GUID-03611-10001 Vol 1 R04, OPG Probabilistic Risk Assessment (PRA) Guide – Level 1 (At-Power), October 24, 2014]). In the Outage PSA guide, the section on Human Reliability Analysis discusses how operator error associated with establishing the required mitigating system configuration within specified recall times is also a consideration for Outage PRA Human Interaction modeling, including operator actions for the manual initiation of mitigating systems during shutdown (i.e., operator action to establish back-up and emergency heat sinks). Therefore, the information and main assumptions regarding operator actions for heat sink operation, maintenance and recall are documented. No further action is required. (SF1-AG20)

B.39. GI-39 CSA N290.14 - Qualification of Digital Hardware and Software for Use in I&C Applications

SECTION 1 - GI-39 GLOBAL ISSUE SUMMARY					
The goal of GI-39, CSA N290.14 - Qualification of Digital Hardware and Software for Use in I&C Applications, is to assess and resolve the lack of a review of legacy Real-Time Process Computing (RTPC) software against CSA N290.14. This Global Issue comprises one Acceptable Deviation addressing one SF1 code review Gap [CSA N290.14-15]. GI-39 is Safety Significance Level 4 based on deterministic defence-in-depth considerations. OPG has an RTPC program, Software [N-PROG-MP-0006 R010, *Software*, June 2, 2017], in place that adequately deals with both legacy and new RTPC software installations in a manner that meets applicable standards and the intent of the CSA standard. The program identifies the processes and overall requirements for an effective Software Program that supports safe and efficient plant operation. Evaluation of the legacy software installations with respect to the CSA N290.14-15 requirements is not practicable and would provide very little safety benefit. On this basis, and given its very low Safety Significance, this issue is assessed as an Acceptable Deviation.					
Safety Significance Level:	4	**Category:**	Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-39 ASSOCIATED GAPS	
SF1-19	Correspondence with the CNSC identifies all of the software application qualifications for software Categories 1, 2 and 3 from January 1, 2007 to the time of the correspondence (June 2016). However, an evaluation of legacy Real-Time Process Computing applications with respect to the requirements of N290.14-15 for Categories 1, 2 and 3 software has not been performed. Therefore, this has been identified as a PSR2 gap. ***Code Review N290.14-15*** **Associated Resolutions:** GI-39-AD1

SECTION 3 - GI-39 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains one SF1 Gap related to CSA N290.14-15. Compliance with CSA-N290.14 is not currently a licence requirement for Pickering NGS (in accordance with PROL 48.03/2018) per the R05 Pickering Licence Conditions Handbook. The gap (SF1-19) indicates that the extent or type of qualification of legacy Real-Time Process Computing (RTPC) applications is not identified.

SECTION 4 - GI-39 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	4	N/A	**4**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**4**

Rationale:

This Global Issue is related to evaluation of legacy Real-Time Process Computing applications with respect to the requirements of CSA N290.14-15. As discussed in Section 5 of this Global Issue, all OPG Nuclear software installations are subject to the OPG software program documents. The legacy software applications have decades of successful service, which indicates the adequacy of the current OPG approach and the programmatic implementation.

Regarding deterministic considerations, this Global Issue is assigned Safety Significance Level 4 for Defence in Depth (E1), since this issue is not significant by itself and it has no impact on the level of operational performance. Safety Significance Levels (E2) is not directly applicable since E2 primarily relates to issues that are not directly related to nuclear safety. Hence, the overall Safety Significance Level of 4 for deterministic considerations is dictated by the E1 categorization.

This Global Issue has no direct impact on the probabilistic considerations, i.e., Core Damage Frequency (F1), Defence in Depth (F2), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, the probabilistic considerations are not directly applicable to this issue.

In summary, the overall Safety Significance Level is 4. The successful service of legacy software applications has been demonstrated.

SECTION 5 - GI-39 RESOLUTION PLAN

GI-39-AD1	OPG has a RTPC program in place that adequately deals with both legacy and new RTPC software installations in a manner that meets the intent of the CSA standard and other standards (e.g., International Standards Organization (ISO)/International Electrotechnical Commission (IEC)). The OPG program document N-PROG-MP-0006 [N-PROG-MP-0006 R010, *Software*, June 2, 2017] identifies the processes and overall requirements for an effective Software Program that supports safe and efficient plant operation and that meets the intent

SECTION 5 - GI-39 RESOLUTION PLAN	
	of CSA-N290.14 and other standards. This program applies to software classified as Real-Time Process Computing (RTPC) and Scientific, Engineering and Safety Analysis (SESA) Software or Software Engineering Tools in OPG Nuclear. This includes embedded RTPC software installation in equipment and components (see OPG procedures N-PROC-MP-0099 [N-PROC-MP-0099 R004, OPG Nuclear Procedure, *Development of Real-Time Process Computing Systems*, April 2016] and N-PROC-MP-0049 [N-PROC-MP-0049 R009, OPG Nuclear Procedure, *Procurement of Software and Products Containing Software*, June 2016]). These documents identify: Processes and overall requirements for classification of software. Governing standards for each software categorization defining requirements for software development, maintenance, procurement, qualification, use and retirement and includes the security of RTPC critical cyber assets. All OPG Nuclear software installations are subject to the OPG software program documents. The legacy software applications have decades of successful service, which indicates the adequacy of the current OPG approach and the programmatic implementation. Evaluation of the legacy software installations with respect to the N290.14-15 requirements is not practicable and would provide very little safety benefit. On this basis, and given the very low safety significance (Safety Significance Level 4), this issue is assessed as an Acceptable Deviation. (SF1-19) This Acceptable Deviation also includes/addresses GI-44.

B.40. GI-40 Accident Management

SECTION 1 - GI-40 GLOBAL ISSUE SUMMARY					
The goal of GI-40, Accident Management, is to ensure that the Emergency Mitigating Equipment (EME) Phase 2 activities are completed. This Global Issue comprises one proposed Resolution Statement and a Cross Reference to GI-27 that address two Gaps: one SF1 code review Gap [REGDOC-2.3.2] and one SF1 Additional Gap. GI-40 is Safety Significance Level 3 based on deterministic and probabilistic defence-in-depth considerations. The proposed Resolution Plan primarily comprises activities to ensure completion of the EME Phase 2 project. In addition, a Cross Reference to GI-27 is included because further mitigation of this issue is provided through the risk improvement initiatives referred to in GI-27. Completion of the proposed Resolution Plan will support and strengthen Level 3 and Level 4 defence-in-depth for the extended operating period.					
Safety Significance Level:	3	**Category:**	Engineering	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-40 ASSOCIATED GAPS	
SF1-33	Full provision of Complementary Design Features for Containment integrity as required by Clause 4.2.1 of REGDOC-2.3.2 will be addressed with the completion of Phase 2 Emergency Mitigating Equipment. This work is currently scheduled to be fully implemented by the end of 2017. Since this work is still in progress, it has been identified as a PSR2 gap. ***Code Review CNSC REGDOC-2.3.2*** **Associated Resolutions:** GI-27-RS2, GI-40-RS1
SF1-AG4	An SF1 Gap related to the submission of updated information in response to CNSC observations made during a SAMG drill involving Emergency Mitigating Equipment was identified in [P-CORR-00531-05107, e-Doc 5305945, July 26, 2017]. **Associated Resolutions:** GI-40-RS1

SECTION 3 - GI-40 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains one SF1 Gap related to accident management and one SF1 Additional Gap related to EME implementation. The Gap is completion of Phase 2 of the Emergency Mitigating Equipment (EME) project. EMS and RMS requirements related to CSA N290.3 under GI-37 are addressed through the implementation of Phase 2 EME for Pickering 1,4 and Pickering 5-8. When credit is taken for Phase 2 EME modifications in the station PSAs, the more stringent Administrative Safety Goals for Large

SECTION 3 - GI-40 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

Release Frequency are not presently achieved for Pickering 1,4. Therefore, to satisfy Administrative Safety Goals for Large Release Frequency for Pickering 1,4, OPG has committed to implement additional design, operational and/or analytical enhancements through GI-27-RS2. Implementation of these modifications focuses on prevention of accident progression, by providing a redundant, independent supply of makeup water to the Heat Transport System, Steam Generators, and Calandria for Pickering 1,4. This will provide additional fuel cooling capability, which increases the likelihood of In-Vessel Retention. Per reference [P-REP-09013-00002 R001, *Pickering NGS – Beyond Design Basis Containment Integrity*, January 2014], In-Vessel Retention supports maintenance of Containment integrity following a Beyond Design Basis Accident, allowing the existing FADS to be used.

SECTION 4 - GI-40 PRIORITY DETERMINATION

Safety Significance of Global Issue	**Deterministic Considerations**			**Probabilistic Considerations**								**Overall Safety Significance Level**
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	3	N/A	**3**	N/A	3	N/A	N/A	N/A	N/A	N/A	**3**	**3**

Rationale:

Similar to GI-37, this Global Issue is related to the completion of a number of initiatives, including Phase 2 of the Emergency Mitigating Equipment project, to minimize radiological releases and enhance Containment protection for BDBAs.

Regarding deterministic considerations, this Global Issue is assigned a Safety Significance Level 3 for Defence in Depth (E1) on the basis that the issue is related to minimizing radiological releases for BDBAs (row 3 of Table E1 in the PSR2 Basis Document). Safety Significance Levels (E2) is not directly applicable since this Global Issue can have a direct impact on nuclear safety, whereas E2 primarily relates to issues that are indirectly related to nuclear safety. Hence, the overall Safety Significance Level of 3 for deterministic considerations is dictated by the E1 categorization.

Regarding probabilistic considerations, the issue has a Safety Significance Level of 3 for Reactor Safety - Defence in Depth (F2). This is because the initiatives are related to BDBAs (frequency less than 10^{-5}/y).

This Global Issue has no direct impact on the other probabilistic considerations, i.e., Core Damage

SECTION 4 - GI-40 PRIORITY DETERMINATION

Frequency (F1), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these probabilistic considerations are not directly applicable, and the overall Safety Significance Level of 3 for probabilistic considerations is dictated by the F2 categorization.

In summary, the overall Safety Significance Level is 3. OPG is actively progressing Phase 2 of the Emergency Mitigating Equipment project in support of extended operation at Pickering NGS.

SECTION 5 - GI-40 RESOLUTION PLAN

GI-40-RS1	Complete the planned Phase 2 EME implementation. This includes supplying cooling water, and power to essential loads via EME generators, to allow for operation of Air Cooling Units (ACUs) and Hydrogen Igniters [P-CORR-00531-04945, OPG Correspondence, *Pickering NGS – CNSC Action Item 2016-48-7470 Status Update on Emergency Mitigating Equipment and Telecommunications Projects*, February 16, 2017]. OPG is actively progressing this work in support of extended operation at Pickering NGS. (SF1-33) (SF1-AG4) This Resolution Statement includes/addresses GI-37 and is related to GI-27.
GI-40-XRF-GI-27-RS2	Further mitigation of the requirement for Complementary Design Features for Containment integrity is provided through the risk improvement initiatives referred to in GI-27. (SF1-33)

B.41. GI-41 REGDOC-2.10.1 - Nuclear Emergency Preparedness and Response

SECTION 1 - GI-41 GLOBAL ISSUE SUMMARY					
The goal of GI-41, REGDOC-2.10.1 - Nuclear Emergency Preparedness and Response, is to confirm that OPG governance is in compliance with CNSC REGDOC-2.10.1, Nuclear Emergency Preparedness and Response. This Global Issue comprises one item assessed as requiring No Further Action addressing one SF13 code review Gap [REGDOC-2.10.1]. GI-41 is Safety Significance Level 4 based on deterministic safety significance levels, probabilistic defence-in-depth and probabilistic emergency preparedness considerations. OPG's Consolidated Nuclear Emergency Plan [N-PROG-RA-0001 R015] was revised to address the two specific issues identified in the gap, which are to ensure that the evacuation time estimates and KI pill programs will be sustained. Because this addresses the code review Gap, the issue is assessed as requiring No Further Action.					
Safety Significance Level:	4	**Category:**	Programmatic	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-41 ASSOCIATED GAPS	
SF13-1	OPG has completed a gap analysis for transition to CNSC REGDOC-2.10.1 and has developed an action plan to achieve compliance. The transition plan that OPG has committed in order to bring Darlington into compliance with REGDOC-2.10.1 applies across the nuclear fleet and will also bring Pickering into compliance. Updating OPG governance to ensure that the Pickering Evacuation Time Estimate study is maintained and to define how the Potassium Iodide (KI) pill program will be sustained is in progress. As these two actions are not yet complete, this is identified as a PSR2 gap. ***Code Review CNSC REGDOC-2.10.1*** • **Note – Per GI-41-NFA1, this gap has been fully addressed.** **Associated Resolutions:** GI-41-NFA1

SECTION 3 - GI-41 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains one SF13 gap related to CNSC REGDOC-2.10.1. This gap identifies required updates of OPG governance to bring OPG's Nuclear fleet in compliance with REGDOC-2.10.1 (2014). The specified required actions are to maintain Pickering Evacuation Time Estimates (ETE) and to define how the KI pill program will be sustained. The transition plan for REGDOC-2.10.1 was prepared for Darlington and was subsequently provided to the CNSC in [NK38-CORR-00531-17593, OPG Correspondence, *Darlington NGS – Transition Plan for Regulatory Document Nuclear Emergency Preparedness and Response (REGDOC–2.10.1)*,

SECTION 3 - GI-41 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

September 30, 2015]. Regulatory Management Action Request AR # 28184526 was initiated to track completion of the transition plan.

- AR 28184526-06 was closed with a complete description of the ETE update process followed in 2015/16.
- AR 28184526-09 was closed with a complete description of the KI procurement and distribution process followed in 2015, and the on-going KI availability process developed and maintained.

OPG's nuclear emergency plan was revised [N-PROG-RA-0001 R015, OPG Nuclear Program, *Consolidated Nuclear Emergency Plan*, November 2016] to incorporate the required information, as follows:

> "OPG shall assist the province and designated municipalities in their planning and preparedness for a nuclear emergency, and collaborate with them to:
>
> (a) Develop and maintain public evacuation time estimates based on current census data, and future population growth projections on a per-decade estimation."
>
> "In consultation with the designated municipalities, OPGN EP Department shall procure stable iodine tablets and maintain them within expiry dates on behalf of the nuclear sites. Distribution of iodine tablets is the responsibility of Durham Region and City of Toronto, with the support of OPG.
>
> Initial distribution of stable iodine tablets to residences, businesses and institutions within the Pickering and Darlington Primary Zones was completed in 2015. The program established and maintained by the designated municipalities and OPG ensures continued availability and that information is available to the general public, including online."

SECTION 4 - GI-41 PRIORITY DETERMINATION

Safety Significance of Global Issue	**Deterministic Considerations**			**Probabilistic Considerations**								**Overall Safety Significance Level**
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	N/A	4	**4**	N/A	4	N/A	N/A	N/A	4	N/A	**4**	**4**

SECTION 4 - GI-41 PRIORITY DETERMINATION

Rationale:

This Global Issue is related to required updates of OPG governance to bring Pickering NGS into compliance with REGDOC-2.10.1 (2014). It is related to maintaining Pickering Evacuation Time Estimates (ETE) and to defining how the KI pill program will be sustained.

Regarding deterministic considerations, this Global Issue is not associated with a physical barrier, so Defence in Depth (E1) is not applicable. Safety Significance Levels (E2) is assigned Safety Significance Level 4 since resolution of this issue "may help identify areas that need more attention", in this case the adequacy of governance implementation or its effectiveness. Therefore, a Safety Significance Level of 4 is selected for deterministic considerations.

Safety Significance Level 4 is assigned to probabilistic considerations Defence in Depth (F2) and Emergency Preparedness (F6). This Global Issue pertains to defence–in-depth Level 5 but is expected to have insignificant impact since the issue pertains to sustaining provisions that are already in place. Similarly, for Emergency Preparedness (F6), the Safety Significance Level is 4 because the KI pill program is already in place.

For probabilistic considerations, this Global Issue has no impact on Core Damage Frequency (F1), nor does it impact Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), or Environment (F7). Therefore, these other probabilistic considerations are not applicable.

In summary, the overall Safety Significance Level is 4. As indicated in Section 5 of this Global Issue, the OPG nuclear emergency preparedness governance [N-PROG-RA-0001 R015, OPG Nuclear Program, *Consolidated Nuclear Emergency Plan*, November 2016] was revised to ensure that the evacuation time estimates and KI pill programs will be sustained.

SECTION 5 - GI-41 RESOLUTION PLAN

GI-41-NFA1	The OPG nuclear emergency preparedness governance [N-PROG-RA-0001 R015, OPG Nuclear Program, *Consolidated Nuclear Emergency Plan*, November 2016] was revised to ensure that the evacuation time estimates and KI pill programs will be sustained. No further action is required. (SF13-1)

B.42. GI-42 Examination and Testing Requirements for Design of Concrete Containment Structures

SECTION 1 - GI-42 GLOBAL ISSUE SUMMARY					
The goal of GI-42, Examination and Testing Requirements for Design of Concrete Containment Structures, is to ensure that the Concrete Containment Structures (CCS) remain fit for service for the extended operating period. This Global Issue comprises one Acceptable Deviation addressing one SF1 code review Gap [CSA N287.5-11]. GI-42 is Safety Significance Level 3 based on deterministic defence-in-depth considerations. The CCSs at Pickering A and B were built and tested to meet the 1965 and 1970 National Building Code of Canada requirements, respectively. Ongoing confirmation that the Pickering NGS CCSs remain fit for service is demonstrated via periodic and in-service inspections conducted in accordance with the requirements of CSA N285.5 and CSA N287.7. In addition, the Engineering Change Control program [N-PROG-MP-0001] ensures that any design changes made to the Pickering CCSs will comply with CSA N287.5 going forward. The proposed Resolution Plan assesses the Gap in demonstrating that the CCS design meets CSA N287.5-11 as an Acceptable Deviation because of its very low Safety Significance and because it is being addressed outside of PSR2. The controls in place at the time of construction and the ongoing controls in place for inspections, aging management and modifications adequately meet the intent of CSA N287.5-11.					
Safety Significance Level:	3	**Category:**	Programmatic	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-42 ASSOCIATED GAPS	
SF1-6	The Concrete Containment Structures (CCSs) at Pickering A and B were built and tested to meet the 1965 and 1970 National Building Code of Canada requirements, respectively, prior to the initial issuance of CSA N287.5. No assessments exist which demonstrate that the requirements in effect during construction of Pickering NGS CCSs comply with the requirements of CSA N287.5. Ongoing confirmation that the Pickering NGS CCSs remain fit for service is demonstrated via periodic and in-service inspections conducted in accordance with the requirements of CSA N285.5 and N287.7, and the resultant inspection reports attest to the quality of the design. In addition, the Engineering Change Control process ensures that that any design changes made to the Pickering CCSs will comply with N287.5 going forward, as applicable. The original Pickering construction included requirements for tests and quality control procedures which generally meet the intent of N287.5. Furthermore, retroactive application of N287.5 to the as-built design of CCSs cannot be practically achieved without rebuilding them. Nevertheless, there is a PSR2 gap for Pickering NGS given that compliance with the specific requirements of N287.5 has not been demonstrated.

SECTION 2 - GI-42 ASSOCIATED GAPS

Code Review N287.5-11

Associated Resolutions: GI-42-AD1

SECTION 3 - GI-42 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains one SF1 Gap related to the examination and testing requirements for the design of Concrete Containment Structures (CCSs).

CSA N287.5 is identified in Appendix E.1 of the R05 Pickering Licence Conditions Handbook as *Guidance or Criteria* and is relevant to Section 6.1, Design Program, of the Licence Conditions Handbook. Gap SF1-6 is related to Containment concrete structure design requirements. GI-19 addresses N287.7, in-service examination and testing requirements for Containment Concrete Structures.

SECTION 4 - GI-42 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	3	N/A	**3**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**3**

<u>Rationale:</u>

This Global Issue is related to Containment Concrete Structure design requirements. Specifically, the identified gap states that no assessments exist which demonstrate that the requirements in effect during construction of Pickering NGS Containment Concrete Structures comply with the requirements of CSA N287.5.

Regarding deterministic considerations, this Global Issue is assigned a Safety Significance Level 3 for Defence in Depth (E1) on the basis that the issue is related to but does not impact Containment capability (row 3 of Table E1 in the PSR2 Basis Document). This is because, as indicated in Section 5 of this Global Issue, the controls in place at the time of construction and the ongoing controls in place

SECTION 4 - GI-42 PRIORITY DETERMINATION

for inspections, aging management and modifications adequately meet the intent of CSA N287.5-11. Safety Significance Levels (E2) is not directly applicable since this Global Issue can have a direct impact on nuclear safety, whereas E2 primarily relates to issues without a direct impact on nuclear safety. Hence, the overall Safety Significance Level of 3 for deterministic considerations is dictated by the E1 categorization.

For probabilistic considerations, this Global Issue has no impact on Core Damage Frequency (F1) or Defence in Depth (F2), nor does it impact Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) or Environment (F7). Therefore, probabilistic considerations are not applicable.

In summary, the overall Safety Significance Level is 3. The issue is indirectly addressed by the fact that continuing compliance with CSA N287.7-08 is provided by the existing Containment Periodic Inspection Program and testing programs.

SECTION 5 - GI-42 RESOLUTION PLAN

GI-42-AD1	The Concrete Containment Structures (CCSs) at Pickering A and B were built and tested to meet the 1965 and 1970 National Building Code of Canada requirements, respectively. The standards that applied during original construction of Pickering NGS included requirements for tests and quality control procedures to ensure that the concrete used in the as-built structures met the original design requirements. For Pickering Units 5-8, the original Pickering Concrete Placing and Workmanship Specification [L-715-80, *Pickering Generating Station B L-715-80 Specification for Concrete Placing and Workmanship*] and Tendering and Contract Document [T-NK30-20541-01, *Pickering Generating Station B, Tendering and Contract Documents NK30-LH-20541-01 for Supply of Pre-Mix Concrete in Ready Mix Trucks*, April 19, 1974], included requirements for quality control and compliance with CSA A23.1, A23.2 and A23.3 (which address concrete materials, methods of concrete construction and test methods and standard practices for concrete). For Pickering Units 1,4, the concrete structures were built and tested to meet the 1965 NBCC requirements and associated CSA A23 Series Standards, supplemented by specific loading requirements and the requirements in the Design Manuals. Ongoing confirmation that the Pickering NGS CCSs remain fit for service is demonstrated via periodic and in-service inspections conducted in accordance with the requirements of CSA N285.5 and N287.7, and the resultant inspection reports attest to the quality of the design. In addition, the Engineering Change Control process ensures that any design changes made to the Pickering CCSs will comply with N287.5 going forward. The original Pickering construction included requirements for tests and quality control procedures which generally meet the intent of N287.5. The controls in place at the time of construction and the ongoing controls in place for inspections, aging management and modifications adequately meet the intent of CSA N287.5-11. This issue is of low safety significance (Safety Significance Level 3) and has been addressed to the extent practicable. Therefore this issue is assessed as an Acceptable Deviation. (SF1-6)

B.43. GI-43 Safety-Related Structures (Non-Containment) for Nuclear Power Plants

SECTION 1 - GI-43 GLOBAL ISSUE SUMMARY					
The goal of GI-43, Safety-Related Structures (Non-Containment) for Nuclear Power Plants, is to ensure fitness for service of non-Containment Safety-Related Structures, and to demonstrate conformance to applicable codes and standards for the extended operation period. This Global Issue comprises three proposed Resolution Statements, one Acceptable Deviation and one Cross-Reference to GI-19, which address seven Gaps: three SF1 code review Gaps [CSA N291-15], one SF2 review task Gap, one SF4 code review Gap [CSA N287.7-08] and two COP Review Gaps. GI-43 is Safety Significance Level 3 based on deterministic and probabilistic defence-in-depth considerations. The proposed Resolution Plan primarily comprises activities to perform inspections, develop a risk-based approach in aging management governance, and prepare condition assessments for the extended operating period, for non-Containment safety-significant civil structures. These activities address two of the three SF1 Gaps, and the SF2 and SF4 Gaps. The two COP Review Gaps, which are related to GI-19, FFS of Containment for the Extended Operating Period, are addressed by the proposed Resolution Statement for GI-19. The remaining SF1 Gap is assessed as an Acceptable Deviation since it is being managed and has low Safety Significance. Completion of the proposed Resolution Plan will support and strengthen Level 1 defence-in-depth for the extended operating period.					
Safety Significance Level:	3	**Category:**	Engineering, Programmatic, Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-43 ASSOCIATED GAPS	
SF4-13	Actions #31, #32, and #33 from the Pickering Units 5-8 Continued Operations Plan are related to N287.7 and although complete, need to be reassessed for Pickering operation past 2020. (IIP Action #31 involved submission of Periodic Inspection Plans and Life Cycle Management Plans for a number of safety-significant civil structures. IIP Action #32 involved submission of Aging Management Plans for Concrete Containment Structures to the CNSC for acceptance. IIP Action #33 involved revising the Reactor Building Periodic Inspection Plan and submitting to the CNSC for acceptance.) ***Code Review N287.7-08*** <u>Note:</u> Only Action #31 is covered under this Global Issue. **Associated Resolutions:** GI-43-RS1, GI-43-RS2, GI-43-RS3
SF1-20	Clause 6.5.2.2 of CSA N291-15 imposes new requirements for bolted connections in members that are part of the seismic load resisting system. Pickering NGS structures were not explicitly designed to meet these requirements and this is therefore identified as a PSR2

SECTION 2 - GI-43 ASSOCIATED GAPS	
	gap. ***Code Review N291-15*** **Associated Resolutions:** GI-43-AD1
SF1-21	Clause 9 of CSA N291-15 contains new requirements related to aging management (including design provisions to account for aging) that are not in CSA N291-08 and that may have significance for operation of Pickering beyond 2020. Pickering structures were not explicitly designed to meet these requirements and this is therefore identified as a PSR2 gap. ***Code Review N291-15*** **Associated Resolutions:** GI-43-RS1, GI-43-RS2, GI-43-RS3
SF1-22	Clauses 6.1.1(b) and 6.9.2.1.4 of CSA N291-15 state requirements for aspects of the design that are specifically based on the plant service life. Pickering structures were not explicitly designed or assessed in relation to the requirements of these clauses for operation beyond 2020. This is identified as a PSR2 gap. ***Code Review N291-15*** **Associated Resolutions:** GI-43-RS1, GI-43-RS2, GI-43-RS3
SF2-11	Condition Assessments for civil structures are not complete for station operation to 2028[33]. ***Review Task #1 Actual Condition of SSCs*** **Associated Resolutions:** GI-43-RS1, GI-43-RS2, GI-43-RS3
COP-4	Work has not been completed to demonstrate adequate margin to operate the Pickering High Pressure Emergency Coolant Injection storage tank foundation piles by performing engineering analysis of loss of thickness due to corrosion, for the extended operation period and for the period until the ECIS is no longer required. ***Pickering PSR2 Gap COP-4*** **Associated Resolutions:** GI-19-RS1
COP-25	An assessment of margin to operate all the Pickering Reactor Building foundations has not been completed for the period of extended operation and until Reactor Building integrity can be demonstrated to no longer be required. This issue applies also to the Vacuum Building and Pressure Relief Duct for the extended operation period and for the period until the Negative Pressure Containment System integrity can be demonstrated to no longer be required. ***Pickering PSR2 gap COP-25*** Note 1: Recently CNSC requested OPG (CD# P-CORR-00531-04901 November 28, 2016) to re-consider COP actions F06 and I15-6B with an expanded scope to include the foundation

SECTION 2 - GI-43 ASSOCIATED GAPS

piles supporting the Pickering A Reactor Building, Vacuum Building and Pressure Relief Ducts as part of PSR2, to demonstrate whether the foundation steel H-piles at the Pickering site will withstand their design loads for all civil structures that they support for operation beyond 2020. OPG's path forward was communicated to CNSC staff in [P-CORR-00531-04896 *Pickering NGS: Continued Operations Plan (COP) Actions F06 and I15-6B -Periodic Safety Review Reassessment for Operation Beyond 2020*, January 23, 2017] where it was indicated that PSR2 will consider the expanded scope of COP actions F06 and I15-6B. Additional CNSC feedback was provided in [P-CORR-00531-04973*, Pickering NGS: CNSC Staff Review of OPG's Reassessment of COP Actions for Consideration in the PSR2,* February 24, 2017].

Note 2:

Non-Containment foundation H-piles are addressed in this Global Issue (GI-43).

Associated Resolutions: GI-19-RS1

SECTION 3 - GI-43 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains a total of seven Gaps (three SF1 Gaps, one SF2 Gap, one SF4 Gap and two COP Review Gaps) related to non-Containment safety related structures.

Containment structures are addressed in GI-19.

SF4-13 is shared by this Global Issue and GI-19. The relevant portion of SF4-13 to this Global Issue (GI-43) is Action #31 "Include the periodic inspection programs and LCMPs for the Safety-significant civil structures that are under the scope of CSA N291-08, but not covered by the N287.7 standard". Actions #32 and #33 are related only to Containment structures and are addressed in GI-19.

With respect to COP-25, CNSC staff requested OPG [P-CORR-00531-04901, CNSC Correspondence e-Doc 5129748, *Pickering NGS: Closure of Actions F06 and I15-6b of the Continued Operations Plan (COP)*, November 28, 2016] to re-consider COP actions F06 and I15-6B with an expanded scope to demonstrate whether the foundation steel H-piles at the Pickering site will withstand their design loads for all civil structures that they support for operation beyond 2020. OPG's path forward was communicated to the CNSC in [P-CORR-00531-04896, OPG Correspondence, *Pickering NGS: Continued Operations Plan (COP) Actions F06 and I15-6B - Periodic Safety Review Reassessment for Operation Beyond 2020*, January 23, 2017] where it was indicated that PSR2 will address the expanded scope of COP actions F06 and I15-6B. Additional CNSC feedback was provided in [P-CORR-00531-04973, CNSC Correspondence e-Doc 5189874, *Pickering NGS: CNSC Staff Review of OPG's Reassessment of COP Actions for Consideration in the PSR2*, February 24, 2017]. Consideration of the integrity of H-piles supporting Reactor Buildings, Pressure Relief Duct, and the Vacuum Building structures is addressed in GI-19 while that for H-piles supporting the non-Containment civil structures is addressed in this Global Issue (GI-43).

For non-Containment safety-significant Civil Structures, a Preventive Maintenance program (PM 00121151) has been established. The list of structures included is identified in Memorandum [P-CORR-20000-0608706, OPG Memorandum, *Pickering NGS Inspection Criteria for Non-Containment Buildings and Structures (including safety-related structures and components)*, August 17, 2016]. An

SECTION 3 - GI-43 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

initial inspection will be managed and performed by Pickering Field Engineering in order to identify any degradation. After the initial inspection, the structures and components will be inspected a minimum of once every 5 years. Subsequent inspections will be managed by Station Engineering. The initial inspection will cover all accessible areas, make recommendations for inspections of inaccessible areas, and identify areas that should receive additional examination in future inspections. The first round of these inspections for structures is planned to be completed in 2017 and the inspection results will be documented in an Inspection & Test Plan.

Preventive Maintenance and As-Found Condition results are inputs to Condition Assessments.

There is a requirement to develop Condition Assessments for Safety-Significant Civil Structures. OPG is enhancing its methodology to address Aging Management of non-Containment Safety-Significant Civil Structures. Execution of this methodology will identify critical structures, and establish a means for scoping of non-Containment Safety-Significant Civil Structures for Aging Management consideration.

SECTION 4 - GI-43 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	3	N/A	**3**	N/A	3	N/A	N/A	N/A	N/A	N/A	**3**	**3**

Rationale:

This Global Issue is related to the fitness for service of safety-related structures (Non-Containment).

Regarding deterministic considerations, this Global Issue is assigned a Safety Significance Level 3 for Defence in Depth (E1) on the basis that the issue is related to civil structures associated with safety functions for DBAs (row 3 of Table E1 in the PSR2 Basis Document). Safety Significance Levels (E2) is not directly applicable, since this Global Issue can have a nuclear safety impact, whereas E2 primarily relates to issues without a direct nuclear safety impact. Hence, the overall Safety Significance Level of 3 for deterministic considerations is dictated by the E1 categorization.

Regarding probabilistic considerations, the issue has Safety Significance Level 3 for Reactor Safety - Defence in Depth (F2). This is because the issue is related to the reliability of structures important to

SECTION 4 - GI-43 PRIORITY DETERMINATION
safety for DBAs (initiating frequency less than 10^{-3}/y) and BDBAs. The other probabilistic considerations, i.e., Core Damage Frequency (F1), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7), are not directly applicable. Hence, the overall Safety Significance Level of 3 for probabilistic considerations is dictated by the F2 categorization. In summary, the overall Safety Significance Level is 3. OPG has established a Preventive Maintenance program (PM 00121151) and is also currently progressing this issue by using a risk based approach for aging management of safety-significant civil structures for the extended operating period.

SECTION 5 - GI-43 RESOLUTION PLAN	
GI-43-RS1	Perform the scope of inspections for non-Containment safety-significant civil structures as per the established Preventive Maintenance program (PM 00121151). (SF1-21) (SF1-22) (SF2-11) (SF4-13 Action #31)
GI-43-RS2	Develop program governance using a risk based approach for aging management of safety-significant civil structures for the extended operating period. This applies to non-Containment Safety-Related Civil Structures. (SF1-21) (SF1-22) (SF2-11) (SF4-13 Action #31)
GI-43-RS3	Prepare Condition Assessments as appropriate for safety-significant civil structures for the extended operating period. Recommendations from these Condition Assessments will be tracked and reported along with those related to GI-8. This applies to non-Containment Safety-Related Civil Structures. (SF1-21) (SF1-22) (SF2-11) (SF4-13 Action #31) This Resolution Statement also includes/addresses GI-22.
GI-43-AD1	An assessment of this gap (SF1-20) was completed [P-CORR-03680-0620823, *Re: Resolution for Pickering Periodic Safety Review 2 (PSR2) Global Issue #GI-43 Gap SF1-20*, June 30, 2017]. The original code requirements for PNGS safety related structures [National Building Code of Canada] and the Seismic Margin Assessments (SMA) include requirements of CSA S16 “Design of Steel Structures”, which is the basis for the requirements for bolted connections of steel structures in CSA N291-15. Given that the SMA methodology and the plant design both include requirements of S16/S16.1 (predecessor of S16), the plant meets or has been assessed to these requirements. Structures on seismic success paths have been qualified and/or assessed to meet their performance requirements. In addition, SMA-based Probabilistic Safety Assessments for Pickering Units 1,4 and 5-8 [NA44-REP-03611-00022 R000, *PRA-Based Seismic Margin Assessment of PNGS-A*, January 2014], [NK30-REP-03611-00013 R001, *PRA-Based Seismic Margin Assessment of PNGS-B*, April 2015] demonstrate that risk associated with seismic hazard is sufficiently low. As it would not be practicable to make changes to the bolted steel connections in the existing structural design, and given the low safety significance (Significance Level 3), this

SECTION 5 - GI-43 RESOLUTION PLAN	
	is assessed as an Acceptable Deviation. (SF1-20)
GI-43-XRF-GI-19-RS1	Demonstrate the FFS of the foundation steel H-piles for the Pickering A Reactor Building, Vacuum Building and Pressure Relief Duct at the Pickering site for the extended operating period. (COP-4) (COP-25)

B.44. GI-44 REGDOC-2.5.2 - Design of Reactor Facilities: Nuclear Power Plants

SECTION 1 - GI-44 GLOBAL ISSUE SUMMARY					
The goal of GI-44, REGDOC-2.5.2 – Design of Reactor Facilities: Nuclear Power Plants, is to demonstrate an appropriate degree of conformance with CNSC REGDOC-2.5.2 given that the document applies to new reactors. This Global Issue comprises 10 Acceptable Deviations and one Cross-Reference to GI-39 which address 13 Gaps: ten code review Gaps (eight SF1 Gaps, one SF5 Gap and one SF6 Gap) and three SF1 Additional Gaps. Specifically, the Gaps are related to REGDOC-2.5.2 requirements for deterministic safety analysis, human factors, seismic qualification, Safety Goals, Containment leak tightness, on-demand reliability of safety systems, sharing of systems, operator action time limits, ECI heat exchanger leak detection, safety parameter display systems and their qualification for Design Extension Conditions and use of computer based systems or equipment. GI-44 is Safety Significance Level 3 based on deterministic defence-in-depth and safety significance levels considerations, as well as probabilistic defence-in-depth considerations. Considering the legacy nature of the original Pickering design and construction, and based on the extensive safe operating experience and modifications processes, as well as the low safety significance of the Gaps and considering that practical solutions are not readily evident, the SF1 Gaps and the SF1 Additional Gaps are assessed as Acceptable Deviations. With respect to the SF5 Gap, the REGDOC-2.4.1 implementation plan will be updated. With respect to the SF6 Gap, Pickering NGS meets current safety goals, and, although meeting the safety goals in REGDOC-2.5.2 is not practicable, risk improvement initiatives are being investigated. In summary, the proposed Resolution Plan comprises ten Acceptable Deviations and one Cross-Reference to GI-39, which address the 13 Gaps in this Global Issue.					
Safety Significance Level:	3	**Category:**	Analytical, Programmatic, Engineering	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-44 ASSOCIATED GAPS	
SF5-5	Clauses 4.2.1, 6.4 and 7.3 of REGDOC-2.5.2 introduce new requirements and limits for Anticipated Operational Occurrences (AOOs), Design Basis Accidents (DBAs) and Beyond Design Basis Accidents (BDBAs) and include specific dose limits for AOOs and DBAs. Current Pickering Safety Report analyses do not identify and classify events into these categories. Dose limits currently used in Pickering are aligned with the single failure/dual failure limits in accordance with the Pickering Licence Conditions Handbook. This issue has therefore been identified as a PSR2 gap. It is being addressed as part of REGDOC-2.4.1 implementation. ***Code Review CNSC REGDOC-2.5.2*** **Associated Resolutions:** GI-44-AD1
SF1-30	Human Factors in Design: Clauses 7.21 and 8.10.1 of REGDOC-2.5.2 introduce new requirements for the systematic application of Human Factors Engineering (HFE) principles

SECTION 2 - GI-44 ASSOCIATED GAPS	
	to plant design. Many years of safe and reliable operating experience indicate that the design and processes for integration of human interactions with the plant were and remain robust. However, Pickering plant design predates the current requirements for incorporating HFE into the design and the existing plant has not been systematically demonstrated to meet the requirements for a new plant. Therefore, this has been identified as a PSR2 gap. ***Code Review CNSC REGDOC-2.5.2*** **Associated Resolutions:** GI-44-AD2
SF1-29	Seismic Qualification and Design: Clause 7.13.1 of REGDOC-2.5.2 requires that Beyond Design Basis (BDB) Earthquake seismic margin be a factor of 1.67 beyond that required for the new plant Design Basis Earthquake (DBE). Fragility evaluations were completed for seismic mitigating SSCs, however, based on available information it could not be confirmed that the new plant BDB Earthquake margin of 1.67 would be achieved. Therefore, this has been identified as a PSR2 gap. ***Code Review CNSC REGDOC-2.5.2*** **Associated Resolutions:** GI-44-AD3
SF6-5	Clause 4.2.2 of REGDOC-2.5.2 introduces new requirements and limits for probabilistic analysis risk limits, such as a Core Damage Frequency limit of less than 10^{-5}/y. It has not been demonstrated that these requirements can be achieved. Therefore, this has been identified as a PSR2 gap. ***Code Review CNSC REGDOC-2.5.2*** **Associated Resolutions:** GI-44-AD4
SF1-25	Containment Leak Tightness for Design Extension Conditions (DECs): Clauses 7.3 and 8.6.12 of REGDOC-2.5.2 require Containment to provide a leak tight barrier following DECs with severe core damage for a period sufficient to implement off-site emergency measures. REGDOC-2.5.2 guidance suggests this period be at least 24 hours. Such an explicit requirement does not exist in Beyond Design Basis Accident (BDBA)/ severe accident mitigation, so this represents a PSR2 gap. ***Code Review CNSC REGDOC-2.5.2*** **Associated Resolutions:** GI-44-AD5
SF1-26	On-Demand Reliability of Safety Systems: Clause 7.6 of REGDOC-2.5.2 requires all SSCs important to safety to meet an on-demand failure rate less than 10^{-3}/y. This requirement is not met for several systems including Pickering 1,4 Emergency Coolant Injection (ECI) and is therefore identified as a PSR2 gap. ***Code Review CNSC REGDOC-2.5.2*** **Associated Resolutions:** GI-44-AD6
SF1-27	Sharing of Safety Systems and Turbine Hall: Clause 7.6.5 of REGDOC-2.5.2 has a new requirement that sharing of safety systems and the turbine generator building not be

SECTION 2 - GI-44 ASSOCIATED GAPS	
	permitted. Pickering Units share Emergency Coolant Injection (ECI) and Negative Pressure Containment, as well as the turbine hall; therefore, this has been identified as a PSR2 gap. ***Code Review CNSC REGDOC-2.5.2*** **Associated Resolutions:** GI-44-AD7
SF1-28	Allowable Times for Crediting On-site Operator Actions: Clauses 7.10 and 8.10.4 of REGDOC-2.5.2 establish new time limits for crediting operator actions, i.e., 30 minutes for Main Control Room (MCR) actions and 1 hour for field actions. Pickering NGS has not demonstrated that deterministic safety analysis consequences are acceptable if MCR and field action are not credited for these times respectively. Therefore, this has been identified as a PSR2 gap. ***Code Review CNSC REGDOC-2.5.2*** **Associated Resolutions:** GI-44-AD8
SF1-31	Detection/Isolation of Emergency Coolant Injection (ECI) Heat Exchanger (HX) Tube Leak: Clause 8.5 of REGDOC-2.5.2 requires ECI recovery heat exchanger tube leak detection capability. Pickering Units 5-8 ECI recovery heat exchangers do not have leak detection capability on the cooling water side. Therefore, this has been identified as a PSR2 gap. ***Code Review CNSC REGDOC-2.5.2*** **Associated Resolutions:** GI-44-AD9
SF1-32	Safety Parameter Display System Qualification for Design Extension Conditions (DECs): Clause 8.10.1.1 of REGDOC-2.5.2 requires the Main Control Room (MCR) to contain a Safety Parameter Display System (SPDS) that presents sufficient information on safety-critical parameters for the diagnosis and mitigation of Design Basis Accidents (DBAs) and DECs. The SPDSs are to be qualified for DEC and have parameters available in both the MCR and Secondary Control Areas (SCA), per Clause 8.10.2. Pickering SPDSs are not Review Level Condition (RLC) qualified or available in all locations. As part of the follow-up to the 2011 Fukushima accident, instrumentation to support critical parameters required to function for DECs has been evaluated for survivability. The instrument loops associated with these parameters have been identified for use in Critical Safety Parameter Monitoring (CSPM) and Beyond Design Basis Accident (BDBA) procedures. However, the indications from these loops are not in one central location and, in some cases, require field action (e.g., power) to obtain data. This does not fully satisfy the requirements to have these parameters available from a SPDS in the MCR and SCA. Therefore, this has been identified as a PSR2 gap relating to the new plant requirement to have SPDS that is DEC qualified and with parameters available in the MCR and SCA. ***Code Review CNSC REGDOC-2.5.2*** **Associated Resolutions:** GI-44-AD10
SF1-AG17	An SF1 Gap related to the absence of a Safety Parameter Display System in Pickering A and B, and in emergency response facilities, was identified in [P-CORR-00531-05107, e-Doc 5305945, July 26, 2017].

SECTION 2 - GI-44 ASSOCIATED GAPS

	Associated Resolutions: GI-44-AD10
SF1-AG18	An SF1 Gap related to an assessment of Section 7.9.2 of REGDOC-2.5.2 for the use of computer based systems or equipment, i.e., Digital Controllers, was identified in [P-CORR-00531-05107, e-Doc 5305945, July 26, 2017]. **Associated Resolutions:** GI-39-AD1
SF1-AG19	An SF1 Gap related to the analysis of AOOs, as required by Section 9.1 of REGDOC-2.5.2 was identified in [P-CORR-00531-05107, e-Doc 5305945, July 26, 2017]. **Associated Resolutions:** GI-44-AD1

SECTION 3 - GI-44 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

GI-44 contains 13 Gaps: eight SF1 Gaps, one SF5 Gap, one SF6 Gap and three SF1 Additional Gaps related to REGDOC-2.5.2. Some of these Gaps are similar to issues covered by other Global Issues, as identified in the Resolution Plan.

Compliance with REGDOC-2.5.2 is not currently a licence requirement for Pickering NGS (in accordance with PROL 48.03/2018) per the R05 Pickering Licence Conditions Handbook.

SECTION 4 - GI-44 PRIORITY DETERMINATION

Safety Significance of Global Issue	**Deterministic Considerations**			**Probabilistic Considerations**								**Overall Safety Significance Level**
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	3	3	**3**	N/A	3	N/A	N/A	N/A	N/A	N/A	**3**	**3**

Rationale:

This Global Issue includes 13 gaps that are related to modern design requirements for nuclear power plants. The gaps are related to requirements for deterministic safety analysis, human factors, seismic qualification, Safety Goals, Containment leak tightness, on-demand reliability of safety systems,

SECTION 4 - GI-44 PRIORITY DETERMINATION

sharing of systems, operator action time limits, ECI heat exchanger leak detection, safety parameter display systems and their qualification for Design Extension Conditions, and use of computer based systems or equipment. Some of these gaps are similar to issues covered by other Global Issues.

Regarding deterministic considerations, this Global Issue comprises some gaps that pertain to physical barriers, and other gaps that do not have a direct impact on nuclear safety. Therefore, both considerations E1 and E2 are applicable. Defence in Depth (E1) is assigned Safety Significance Level 3 because the gaps do not identify any impairment in the physical barriers for defence-in-depth. Resolution of the relevant gaps may enhance defence-in-depth barriers, so row 3 of Table E1 of the PSR2 Basis Document is applicable. Safety Significance Levels (E2) is assigned a Safety Significance Level 3. This is consistent with the prioritization of the Global Issues that are related to other REGDOC-2.5.2 gaps (For example, GI-31 addresses issues that are related to REGDOC-2.5.2 gap SF5-5). The remaining issues are not significant by themselves and do not identify adverse conditions for current safe operation (row 3 of Table E2 in the PSR2 Basis Document). Hence, the overall Safety Significance Level of 3 for deterministic considerations is dictated by the E1 and E2 categorizations.

Regarding probabilistic considerations, this Global issue is assigned Safety Significance Level 3 for Reactor Safety - Defence in Depth (F2). This is because resolution of some of the gaps would enhance safety margin on a primary parameter of a System Important to Safety or the reliability of a structure important to safety for DBAs (initiating frequency less than 10^{-3}/y) and BDBAs. The other probabilistic considerations, i.e., Core Damage Frequency (F1), Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7), are not directly applicable. Hence, the overall Safety Significance Level of 3 for probabilistic considerations is dictated by the F2 categorization.

In summary, the overall Safety Significance Level for this Global Issue is 3. Most of the gaps within this Global Issue are similar to issues covered by other Global Issues, and the remaining gaps are not significant.

SECTION 5 - GI-44 RESOLUTION PLAN

GI-44-AD1	Consideration of deterministic safety analysis covering required potential event sequences and specific dose limits introduced by REGDOC-2.5.2 are addressed under REGDOC-2.4.1 implementation. The REGDOC-2.4.1 Implementation Plan will be updated in accordance with the Licence Conditions Handbook and will identify any changes required to support the continued safe operation of Pickering NGS. (Addressed in GI-31) These changes will be informed by the timeline of the Darlington REGDOC-2.4.1 Implementation Plan and the limited additional years of Pickering NGS operation. With the current deterministic analyses, dose limits for event sequences are as defined in the Licence Conditions Handbook (for single failure and dual failure sequences) and OPG is compliant with those requirements as demonstrated through the accident analyses in the Pickering Safety Reports. The DBA events bound the AOO sequences in terms of system response and consequences. In addition, the Pickering NGS PSAs consider a full range of event sequences – covering AOO-type events, DBAs and BDBAs. Pickering NGS meets its required Risk-based Safety Goals as demonstrated through the PSAs. REGDOC-2.5.2 includes general high level requirements where their intent is met

SECTION 5 - GI-44 RESOLUTION PLAN	
	by Pickering NGS Safety Reports and PSA consideration of PIEs. (SF1-AG19) A practicable solution to addressing the gap against the specific requirements of REGDOC-2.5.2 on event identification and classification into Anticipated Operational Occurrences (AOOs), Design Basis Accidents (DBAs) and Beyond Design Basis Accidents (BDBAs) and the dose limits for AOOs and DBAs, and implementing any enhancements within the time available during extended operation, is not readily evident and would provide limited safety benefit. On this basis, and given the low safety significance (Safety Significance Level 3), this is assessed as an Acceptable Deviation. (SF5-5)
GI-44-AD2	Human Factors in Design. The original design phase of Pickering NGS recognized the need for focus on the operator interfaces in the control centres, and on recognition of the integrated whole of the control centre and the related human-systems interfaces. The Pickering units as a result have decades of safe operation and operating experience with monitoring, operation, testing, maintenance and training (including simulators). With regards to plant modifications, all plant modifications are required to be completed in compliance with N-PROG-MP-0001 [N-PROG-MP-0001 R015, OPG Nuclear Program, *Engineering Change Control* May 12, 2017], which includes the requirements for Human Factors and Ergonomics to be considered in design. If the modification is judged to have an HFE impact, a Human Factors Engineering Specialist must concur with the Human Factors Level of Activity. The modification may require the preparation of the Human Factors Engineering Plan or the Human Factors Worksheet. These instructions and processes ensure that the human-system interface elements for the modification are addressed. The technical, design and operator reviews, during and following the design process and via the Availability for Service (AFS) process, ensure the usability requirements will be achieved. Based on the extensive operating experience and modifications processes, there is no justification for revisiting the overall Main Control Room design from an HF perspective. On this basis, and as per the low safety significance (Safety Significance Level 3), and that the issue is being managed to the extent practicable, it is assessed as an Acceptable Deviation. Human factors issues are also addressed in GI-35. (SF1-30)
GI-44-AD3	Beyond Design Basis Seismic Margin. Pickering safety-related structures were designed and analyzed in accordance with the applicable Standards current at the time. Seismic-related enhancements have been made to the plant through the course of plant operation. Both Pickering 1,4 and Pickering 5-8 performed PSA-based seismic margin assessments (SMA) [P-REP-03611-00006-R000, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014] that demonstrated acceptable plant level seismic capacities and acceptable plant risk resulting from seismic events. The SMAs demonstrated that the plant has adequate capability to respond to BDBAs. Beyond Design Basis Nuclear Safety Enhancements are evaluated for seismic robustness using a Review Level Earthquake that exceeds the Design Basis Earthquake as detailed in [N-GUID-01130-10000 R01, *Modifications for Beyond Design Basis Accidents*, February 6, 2015]. Beyond Design Basis seismic capacity has been implemented

SECTION 5 - GI-44 RESOLUTION PLAN	
	at the plant to the extent practicable. This gap relates to the non-mandatory guidance section of REGDOC 2.5.2 in this regard. On this basis, and given the low safety significance (Safety Significance Level 3), this is assessed as an Acceptable Deviation. (SF1-29)
GI-44-AD4	Safety Goals for New Build Reactors: Pickering NGS meets its current Safety Goals. Due to the legacy nature of the Pickering original design and construction, meeting REGDOC-2.5.2 Safety Goals for new nuclear power plants is not practicable. Risk improvement initiatives continue to be developed to further mitigate this and align with all modern Canadian Nuclear Power Plants (see GI-27-RS2). The residual impact is deemed to be a low safety significance issue (Safety Significance Level 3) and is being addressed to the extent practicable. Therefore, it is assessed as an Acceptable Deviation. (SF6-5)
GI-44-AD5	Containment Leak Tightness: The requirement of Containment leak tightness for a period sufficient to implement off-site emergency measures cannot be explicitly demonstrated since an explicit set of DECs is not identified within the licensing basis. The current engineered provisions provide a sufficient Containment barrier to ensure compliance with existing Safety Goals. Beyond Design Basis provisions using Emergency Mitigating Equipment and SAMG provide additional means of protecting Containment integrity against potential accident sequences. Risk improvement initiatives continue to be developed to further mitigate this issue (see GI-27-RS2). Furthermore, due to the nature of the Pickering design and construction, it is not practicable to retrofit a leak tightness barrier for a period sufficient to implement off-site emergency measures following certain BDBAs. This is a low safety significance issue (Safety Significance Level 3) and is being managed to the extent practicable. Therefore, it is assessed as an Acceptable Deviation. (SF1-25)
GI-44-AD6	On-Demand Reliability of Safety Systems. It is not practicable to implement retroactive design modifications to meet the REGDOC-2.5.2 stated unavailability for some safety systems. However, safety system performance is closely scrutinized and monitored, and established unavailability targets and performance of all safety systems are monitored and reported annually in the Annual Risk and Reliability Report [P-REP-09051.1-00016-R000, OPG Report, *Pickering NGS – 2016 Annual Risk and Reliability Report*, March 31, 2017]. The current engineered provisions provide sufficient functionality to ensure compliance with PSA Safety Goals. This is a low safety significance issue (Safety Significance Level 3) and is being managed to the extent practicable. Therefore, it is assessed as an Acceptable Deviation. (SF1-26)
GI-44-AD7	Sharing of Systems. The main impacts of sharing of ECI and Containment are addressed since if either ECI or Containment is unavailable, all affected units are considered impaired and must shutdown within specified time limits, hence reducing the risk of a coincidental DBA. Moreover environmental conditions in the common turbine building have been assessed and credited provisions have been protected to ensure the ability to shutdown/control, cool and monitor remains

SECTION 5 - GI-44 RESOLUTION PLAN	
	available on non-accident units. Required Safety Goals are met. This is a low safety significance issue (Safety Significance Level 3) and the impact of the clause requirement is addressed as shown above. It is impracticable to achieve direct compliance due to the nature of the Pickering design and construction. Thus, this is assessed as an Acceptable Deviation. (SF1-27)
GI-44-AD8	Operator Action Time Credits. REGDOC-2.5.2 requirements for allowable times for operator action from the MCR or the field are more limiting than the corresponding requirements of REGDOC-2.4.1. Pickering A and B Safety Report credits for operator actions from the MCR and in the field are consistent with REGDOC-2.4.1 requirements of 15 and 30 minutes, respectively. The ability to execute required actions within these time limits has been demonstrated through decades of operation, through effective training and testing programs. The gap against the corresponding REGDOC 2.5.2 requirements is a low safety significance issue (Safety Significance Level 3) and has been addressed to the extent practicable. Therefore, it is assessed as an Acceptable Deviation. (SF1-28) This Acceptable Deviation also includes/addresses GI-31.
GI-44-AD9	ECI Heat Exchanger Leak Detection. Pickering 5-8 has ECI recovery piping, pumps and heat exchangers outside of Containment. Components penetrating and outside Containment are all DBE qualified and Nuclear Class 2 [NK30-DM-33350-00002 R003, *Emergency Coolant Injection System Part 1 – General Requirements and Overview*, May 17, 2017], in accordance with the Design Guide [NK30-REF-68000-0379145 R001, Atomic Energy of Canada Limited (AECL) Engineering Design Guide, DG-30-68000-6 R001, *Containment Provisions for Extensions of the Containment Envelope for Pickering Generating Station 'B'*, May 1, 1977]. Since the intent of leakage detection is served by the system leakage collection, recovery and radiation monitoring in the vicinity, the added benefit of implementing a design modification for direct leakage detection is a low safety significance issue (Safety Significance Level 3) and has been addressed to the extent practicable. Therefore, it is assessed as an Acceptable Deviation. (SF1-31)
GI-44-AD10	Pickering NGS has the appropriate indications and alarms in the Main Control Room (and in secondary areas should the Main Control Room become uninhabitable) to inform Operations staff of mitigating system action and changes in key plant parameters such that initiating events can be controlled. The capability to monitor post-accident conditions remotely from the Main Control Room is provided in the SDSE Instrument Rooms for Units 1,4 and in the Unit Emergency Control Centres for Units 5-8. All OPG Nuclear emergency facilities have the capability to access WebEOC, which is a web-based information management software tool used by the Emergency Response Organization (ERO) that allows real-time information posting and multidirectional communication over an Internet connection [OPG Guideline, N-GUID-03491-10000 R000, WebEOC User's Guide, June 30, 2009]. P-MAN-03490-00002, "Pickering ERO Equipment and Facility Manual" provides requirements and direction for Pickering ERO facilities configuration management

SECTION 5 - GI-44 RESOLUTION PLAN	
	and maintenance to ensure readiness, and to provide contingency actions, in accordance with the Consolidated Nuclear Emergency Plan. However, the Safety Parameter Display System cannot be demonstrated to be Design Extension Condition (DEC) qualified since an explicit set of DECs is not identified within the licensing basis. As part of the follow-up to the 2011 Fukushima accident, instrumentation to support critical parameters required to function for BDBAs has been evaluated for survivability in [N-REP-09013-10007 R000, OPG Report, *Ontario Power Generation Severe Accident Management Guidance Instrumentation and Equipment Survivability - Summary Report*, December 13, 2013]. Additionally, as part of FAI 1.8.1 deliverables, OPG has completed the site specific instrumentation and equipment survivability assessments and has prepared a plan and schedule for identified SAMG response enhancements [N-REP-09013-10009 R000, *Information to Support Closure of FAI 1.8.1 - Survivability Assessments for Equipment and Instrumentation for Severe Accident Management*, December 17, 2013]. The instrument loops associated with these critical parameters have been identified for use in CSPM and BDBA accident procedures. The indications from these loops are not in one central location and, in some cases, require field action (e.g., power) to obtain data. Since the intent of this requirement is met as demonstrated above, the added benefit of implementing a design modification addressing this gap is not significant. This is a low safety significance issue (Safety Significance Level 3) and has been addressed to the extent practicable with enhancements identified in N-REP-09013-10009. Therefore, it is assessed as an Acceptable Deviation. (SF1-32) (SF1-AG17)
GI-44-XRF-GI-39-AD1	The PSR2 code review of REGDOC-2.5.2 specifies that the only identified Gap against Clause 7.9.2 is the same Gap identified in the code review of CSA N290.14 (2015) relating to qualification of hardware and software. The Gap is related to absence of categorization and qualification for some legacy real-time process computing applications. This Gap is applicable to Clause 7.9.2 of REGDOC-2.5.2 and it is addressed in GI-39. The review of CSA N290.14 (2015) found that new applications and changes comply with the standard. Since the only identified Gap against clause 7.9.2 of REGDOC-2.5.2 is addressed in GI-39, this Gap is addressed by GI-39. (SF1-AG18)

B.45. GI-45 CRN Concession for Fire Protection Components

SECTION 1 - GI-45 GLOBAL ISSUE SUMMARY					
The goal of GI-45, CRN Concession for Fire Protection Components, is to confirm that the existing exemption from the requirement to have a Canadian Registration Number (CRN) for certain fittings and components associated with Fire Protection Systems is applicable for the extended operating period. This Global Issue comprises one item requiring No Further Action which addresses one SF1 Gap identified from a review of the Pickering Licence Conditions Handbook. GI-45 is Safety Significance Level 4 based on deterministic safety significance levels considerations. The CNSC exemption was an industry-wide initiative and is not time dependent. Therefore, the SF1 Gap requires No Further Action.					
Safety Significance Level:	4	**Category:**	Programmatic	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-45 ASSOCIATED GAPS	
SF1-36	Section 6.2 of the Pickering Licence Conditions Handbook [CNSC Report, LCH-PNGS-R004, *Pickering NGS: Licence Conditions Handbook,* December 23, 2015] outlines a concession related to exemption from requiring a Canadian Registration Number (CRN) for certain fittings and components associated with Fire Protection Systems. This concession will need to be considered in the context of Pickering PSR2 for operation past 2020 and is therefore a gap for Pickering PSR2. ***Additional Review Findings*** • **Note – Per GI-45-NFA1, this gap has been fully addressed.** **Associated Resolutions:** GI-45-NFA1

SECTION 3 - GI-45 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains one SF1 gap related to a concession for exemption from requiring a Canadian Registration Number (CRN) for certain fittings and components associated with Fire Protection Systems. The inclusion of this exemption into the Pickering Licence Conditions Handbook [LCH-PNGS-R004, *Pickering NGS Licence Conditions Handbook*, December 2015] was initiated as part of the CNSC's move towards a more risk-informed regulatory approach and also to ensure consistency amongst licencees [P-CORR-00531-02957, *Regulatory Approval of Pressure Retaining Components*, October 24, 2005]. This exemption eliminated the need for CNSC staff to approve non-risk significant registration and classification of modifications to existing registered systems. This was an industry-wide initiative. There is no time-dependence associated with this concession. [P-CORR-03680-

SECTION 3 - GI-45 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

0620817, *Resolution Plan for Pickering Periodic Safety Review 2 (PSR2) Global Issue #GI-45*, May 25, 2017].

SECTION 4 - GI-45 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	N/A	4	**4**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**4**

Rationale:

This Global Issue is related to the Licence Conditions Handbook exemption on the classification of Fire Protection Systems and associated fittings and components. As discussed in Section 5 of this Global Issue, this concession has industry-wide application and is not affected by Pickering NGS operation beyond 2020. Nevertheless, the Safety Significance Level is determined in accordance with the Global Assessment process.

Regarding deterministic considerations, this Global Issue is not associated with a physical barrier, so Defence in Depth (E1) is not applicable. Safety Significance Levels (E2) is assigned Safety Significance Level 4 since the Licence Conditions Handbook exemption on the classification of Fire Protection Systems and associated fittings and components is assessed to be applicable for Pickering NGS operation beyond 2020. Therefore, a Safety Significance Level of 4 is selected for deterministic considerations.

For probabilistic considerations, this Global Issue has no impact on Core Damage Frequency (F1) or Defence in Depth (F2), nor does it impact Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) or Environment (F7). Therefore, probabilistic considerations are not applicable.

In summary, the overall Safety Significance Level is 4. This Licence Conditions Handbook exemption is not affected by Pickering NGS operation beyond 2020.

SECTION 5 - GI-45 RESOLUTION PLAN	
GI-45-NFA1	The concession for exemption from requiring a Canadian Registration Number (CRN) for certain fittings and components associated with Fire Protection Systems, as detailed in the Pickering Licence Conditions Handbook, has industry-wide application and is not affected by Pickering NGS operation beyond 2020. [P-CORR-03680-0620817, *Resolution Plan for Pickering Periodic Safety Review 2 (PSR2) Global Issue #GI-45*, May 25, 2017] No further action is required. (SF1-36)

B.46. GI-46 Requirements of National Fire Code of Canada for Units 1 & 4 Standby Generator Fuel Tanks

SECTION 1 - GI-46 GLOBAL ISSUE SUMMARY					
The goal of GI-46, Requirements of National Fire Code of Canada (NFCC) for Units 1 & 4 Standby Generator Fuel Tanks, is to demonstrate conformance with the NFCC. This Global Issue comprises one item requiring No Further Action which addresses one COP Review Gap for Pickering 1,4 related to NFCC Clause 4.5.6.7. GI-46 is Safety Significance Level 4 based on deterministic safety significance levels considerations. NFCC Clause 4.5.6.7 requires that piping for flammable liquids or combustible liquids be located aboveground where the piping enters a building. Upgrades were made to the Pickering 1,4 fuel oil systems as part of Pickering A Return to Service, resulting in aboveground location for all of the relevant piping. Therefore, the proposed Resolution Plan comprises one No Further Action item which addresses the COP Review Gap.					
Safety Significance Level:	4	**Category:**	Analytical	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-46 ASSOCIATED GAPS	
COP-18	An assessment that shows that Standby Generator fuel tanks supporting units 1,4 comply with NFCC could not be found. ***Pickering PSR2 Gap COP-18*** • **Note – Per GI-46-NFA1, this gap has been fully addressed.** **Associated Resolutions:** GI-46-NFA1

SECTION 3 - GI-46 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains one COP Review Gap related to requirements of the National Fire Code of Canada (NFCC) for the Pickering Units 1,4 Standby Generator fuel oil systems, with respect to location of fuel oil piping. The PSR2 review of COP Gaps [P-REP-03680-00024 R000, *Pickering 5-8 Continued Operations Plan Review in Support of PNGS Periodic Safety Review 2*, January 17, 2017] identified this COP Gap as applicable to Pickering Units 1,4 since evidence was not found to demonstrate that the Pickering Units 1,4 Standby Generator fuel oil systems were compliant with the requirement of NFCC Clause 4.5.6.7, which requires that piping for flammable liquids or combustible liquids be located aboveground where the piping enters a building. Further investigation has identified that upgrades made to the Pickering 1,4 fuel oil systems as part of the Pickering A Return to Service work have resulted in aboveground

SECTION 3 - GI-46 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

location for all of the relevant piping [NA44-REP-54600-00002, R000, *Available for Service Report – Installation of Standby Generator Aboveground Fuel Oil Piping System*, June 2002]. [P-CORR-03680-0620818, *Resolution Plan for Pickering Periodic Safety Review 2 (PSR2) Global Issue #GI-46*, May 25, 2017]

SECTION 4 - GI-46 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	N/A	4	**4**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**4**

Rationale:

This Global Issue is related to requirements of the National Fire Code of Canada (NFCC) for the Pickering Units 1,4 Standby Generator fuel oil systems, with respect to location of fuel oil piping. As discussed in Section 5 of this Global Issue, further investigation has identified that upgrades made to the Pickering 1,4 fuel oil systems as part of the Pickering A Return to Service work have resulted in aboveground location for all of the relevant piping. Nevertheless, the Safety Significance Level is determined in accordance with the Global Assessment process.

Regarding deterministic considerations, this Global Issue is not associated with a physical barrier. Therefore, Defence in Depth (E1) is not applicable. Safety Significance Levels (E2) is assigned Safety Significance Level 4 because as indicated in Section 5 of this Global Issue, this issue is addressed by upgrades made to the Pickering 1,4 fuel oil systems as part of the Pickering A Return to Service work. Therefore, a Safety Significance Level of 4 is selected for deterministic considerations.

For probabilistic considerations, this Global Issue has no impact on Core Damage Frequency (F1) or Defence in Depth (F2), nor does it impact Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) or Environment (F7). Therefore, probabilistic considerations are not applicable.

In summary, the overall Safety Significance Level is 4. This issue is already addressed by upgrades meeting NFCC requirements with respect to location of fuel oil piping.

SECTION 5 - GI-46 RESOLUTION PLAN	
GI-46-NFA1	Upgrades made to the Pickering 1,4 fuel oil systems as part of the Pickering A Return to Service work have resulted in aboveground location for all of the relevant piping [NA44-REP-54600-00002, *Available for Service Report – Installation of Standby Generator Aboveground Fuel Oil Piping System*, June 07, 2002], which addresses the issue in the COP-18 Gap. [P-CORR-03680-0620818, *Resolution Plan for Pickering Periodic Safety Review 2 (PSR2) Global Issue #GI-46*, May 25, 2017] No further action is required. (COP-18)

B.47. GI-47 Fire Protection Code NFPA 24

SECTION 1 - GI-47 GLOBAL ISSUE SUMMARY					
The goal of GI-47, Fire Protection Code NFPA 24, is to demonstrate conformance with the 2016 version of the National Fire Protection Association Code NFPA 24. This Global Issue comprises one proposed Resolution Statement and one item requiring No Further Action, which address two SF1 code review Gaps [NFPA 24]. One of the SF1 Gaps is related to a deviation against a particular requirement in the 1970 version of NFPA 24, and the other SF1 Gap is related to Pickering 1,4 and 5-8 not being assessed against the most recent version of NFPA 24. GI-47 is Safety Significance Level 3 based on deterministic defence-in-depth considerations. The proposed Resolution Plan for this Global Issue comprises activities which are already in progress to address the deviation against the 1970 version of NFPA 24. To address the SF1 Gap related to Pickering 1,4 and 5-8 not being assessed against the most recent version of NFPA 24, a high level review of Pickering NGS against NFPA 24 was performed in 2017 and resulted in no additional Gaps being identified. Therefore, this Gap requires No Further Action. Completion of the proposed Resolution Plan will support and strengthen defence-in-depth Level 2 and Level 3.					
Safety Significance Level:	3	**Category:**	Programmatic, Analytical, Engineering	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-47 ASSOCIATED GAPS	
SF1-23	For OPG Report NK30-REP-71400-10001 R001, *Fire Protection Code Compliance Review Pickering Nuclear Generating Station B* there is an outstanding issue (Deviation #13301) which relates to NFPA 1970 Section 3601: “Yard post indicator valves at PNGS B are not secured in the open position as required by code” (and which applies to Pickering Units 1,4 as well as Units 5-8). Work to resolve this deviation is currently in progress with locks installed on the majority of the affected valves. Based on OPG List P-LIST-71400-00001 R000, there are a number of SSCs in the yard which directly support plant operation and which are defined as being “related to nuclear safety”. As a result, fire water supply to these SSCs is a credited safety function. Deviation # 13301 is not yet complete. Therefore, this has been identified as a PSR2 gap. ***Code Review NFPA 24*** **Associated Resolutions:** GI-47-RS1
SF1-24	For Pickering Units 5-8 the baseline for NFPA 24 compliance is the 1970 version of the standard. Pickering Units 1,4 have not been previously assessed against NFPA 24. Although recent changes to the 2013 and 2016 versions of NFPA 24 will be addressed in any firewater system design changes going forward (as a result of Code-over-Code reviews performed for NFPA 24), compliance has not been formally documented for Pickering Units 1,4 or Units 5-8 against the most recent versions of NFPA 24. Furthermore, there have been a large number of significant changes to NFPA 24 since 1970, including the 2002 edition which “represented a complete revision of NFPA 24”. Since Pickering NGS has not demonstrated compliance

SECTION 2 - GI-47 ASSOCIATED GAPS

with the 2016 version of NFPA 24, this has been identified as a PSR2 gap. It is noted that OPG is proactively replacing portions of the firewater piping in accordance with NFPA 24, under the Pickering A Firewater Pipe Replacement Project 13-80069.

Code Review NFPA 24

- **Note – Per GI-47-NFA1, this gap has been fully addressed.**

Associated Resolutions: GI-47-NFA1

SECTION 3 - GI-47 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains two SF1 Gaps related to Fire Protection Code NFPA 24.

Following completion of the Safety Factor 1 Report, a code assessment review against the most current version of NFPA 24 (2016) was completed. It is also noted that sections of the buried fire protection piping in the north and south yards in the Pickering A un-zoned area are being replaced under Pickering A Firewater Pipe Replacement Project 13-80069. This proactive modification was undertaken to replace the existing cast iron piping. As identified in OPG Project Charter [NA44-PCH-71450-00001 R000, OPG Project Charter, *Project Charter Buried Fire Pipe Replacement*, March 17, 2014], the main goals of the project are to eliminate the need to isolate major portions of the fire suppression systems due to buried pipe failures and to minimize future failures of the buried cast iron pipe. The new portions of piping will be installed in accordance with NFPA 24.

SECTION 4 - GI-47 PRIORITY DETERMINATION

	Deterministic Considerations			Probabilistic Considerations								
Safety Significance of Global Issue	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	**Overall Safety Significance Level**
	3	N/A	**3**	4	N/A	N/A	N/A	N/A	N/A	N/A	**4**	**3**

<u>Rationale:</u>

This Global Issue is related to Fire Protection Code NFPA 24. Resolution of this Global Issue will complete the installation of wrenches and locks on the Units 5-8 yard Fire Protection System. As

SECTION 4 - GI-47 PRIORITY DETERMINATION
described in Section 5 of this Global Issue, a review against NFPA 24 identified no additional gaps. Regarding deterministic considerations, the relevant safety function is fire protection, but the gap does not impair the capability to terminate a fire event. Therefore, Defence in Depth (E1) is applicable and the Safety Significance Level is 3 based on row 3 of the first column of Table E1 in the PSR2 Basis Document. Safety Significance Levels (E2) is not applicable because the gap relates to a defence-in-depth barrier. Therefore, a Safety Significance Level of 3 is selected for deterministic considerations. For probabilistic considerations, the Probabilistic Safety Assessment includes fire events, but this Global Issue has insignificant impact on Core Damage Frequency (F1). Therefore, Safety Significance Level 4 is assigned. Defence in Depth (F2) is not impacted, nor is Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) or Environment (F7). Therefore, the Safety Significance Level is 4 for probabilistic considerations. In summary, the overall Safety Significance Level is 3. This issue is being addressed by OPG.

SECTION 5 - GI-47 RESOLUTION PLAN	
GI-47-RS1	To resolve deviation #13301 from NK30-REP-71400-10001 R001 [NK30-REP-71400-10001 R001, OPG Report, *Fire Protection Code Compliance Review Pickering Nuclear Generating Station B*, November 23, 2010] the following work orders need to be completed to install wrenches and locks on the 058 Yard Fire Protection System: WO 3259862, 3259894, 3259893. (SF1-23)
GI-47-NFA1	A PSR2 high level review against NFPA 24 (2016) was completed for Pickering NGS [P-CORR-03680-0620821, *Re: Resolution for Pickering Periodic Safety Review 2 (PSR2) Global Issue #47 Gap SF1-24,*, June 9, 2017] (i.e., Gap SF1-23 in GI-47 is the only NFPA 24 gap remaining open). No further action is required. (SF1-24)

B.48. GI-48 CSA N293-12 Fire Protection of Nuclear Power Plants

SECTION 1 - GI-48 GLOBAL ISSUE SUMMARY					
The goal of GI-48, CSA N293-12 Fire Protection of Nuclear Power Plants, is to demonstrate conformance with the CSA nuclear standard on fire protection, CSA N293-12. This Global Issue comprises one proposed Resolution Statement and two Acceptable Deviations, which address three SF1 Gaps which were identified from a code review of CSA N293-12. GI-48 is Safety Significance Level 3 based on deterministic defence-in-depth considerations and probabilistic core damage frequency considerations. The proposed Resolution Plan for this Global Issue comprises activities to interconnect the firewater systems of Units 1,4 and 5-8. These activities address one of the SF1 Gaps. The proposed Resolution Plan assesses the other two SF1 Gaps as Acceptable Deviations, one related to electrical conductors and one related to annunciation and display. Completion of the proposed Resolution Plan will support and strengthen defence-in-depth Level 2 and Level 3.					
Safety Significance Level:	3	**Category:**	Analytical, Engineering	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-48 ASSOCIATED GAPS	
SF1-4	Clause 7.2.1.13 of CSA N293-12 states: “Electrical conductors that are installed in service spaces containing other combustible materials and that are used in connection with fire alarm systems and emergency equipment, including fire alarm cables… shall be capable of performing their intended functions for not less than 1 hour after the start of a fire.” Modifications to the Fire Protection System meet the requirements of CAN/ULC-S524 which mandates a 1 hour fire rating as described in Appendix 1 (Section 2.5) of NA44-DM-71400.2-00001 R001, Section A.2 of NA44-DM-71400-00002 R000 and Section 2 of NK30-DM-71400-00001 R006. This is achieved by the use of Edwards System Technology (EST) that connects the fire alarm control panels via a data communication link with dual redundant circuit wiring paths. However, existing Pyrotronics fire alarm control panels are not similarly connected and, hence, may be susceptible to loss of alarm signal due to spot burning of a cable. While measures such as lack of combustible material in service spaces, combustible transient material control practices, and inherent protection afforded by Pickering NGS cable routing practices used in the Fire Protection Systems mitigate the lack of such a feature, it could not be confirmed based on existing documentation that all essential fire alarm cables are capable of performing their intended functions for not less than 1 hour after the start of a fire to meet the requirement of N293-12 sub-clause 7.2.1.13. As a result, this has been identified as a PSR2 gap. ***Code Review N293-12*** **Associated Resolutions:** GI-48-AD1
SF1-5	Clause 7.3.2.2 (d) of CSA N293-12 states: “At a minimum, the fire protection water pumping system shall consist of at least one diesel-engine-driven fire pump and one electric-motor-

SECTION 2 - GI-48 ASSOCIATED GAPS	
	driven fire pump set, with each pump set being capable of providing, the flow rate and pressure specified in Item (a)". This Clause is met at Pickering Units 1,4 with the provision of diesel-driven firewater pumps, backed up by supplies from the High Pressure Service Water (HPSW) System (as noted in the Pickering A Safety Report NA44-SR-01320-00001 R015, Section 11.5.1.1). It is not met at Pickering Units 5-8, where the Fire Protection System is comprised of the HPSW supplies from the four units only. As a result, Pickering Units 5-8 does not comply with Clause 7.3.2.2 (d) of CSA N293-12 and this has been identified as a PSR2 gap. ***Code Review N293-12*** **Associated Resolutions:** GI-48-RS1
SF1-3	Clause 7.2.1.10.1 of CSA N293-12 states: "A display and control centre shall be located in the MCR (Main Control Room)… capable of providing detailed information on the location and nature of the signal. In addition, the panel operator shall be able to control the fire alarm system without having to leave his or her station." Pickering 014 Display Annunciation Station 014-67140-WS2342 in the Emergency Operating Centre is capable of providing annunciation only, and there is no Display Annunciation Station in the Pickering 014 MCR (although there is limited annunciation). Therefore, this has been identified as a PSR2 gap. ***Code Review N293-12*** **Associated Resolutions:** GI-48-AD1, GI-48-AD2

SECTION 3 - GI-48 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains three SF1 Gaps related to CSA N293-12.

The first gap (SF1-4) is related to the ability of electrical conductors of the original Pyrotronics System 3 Fire Alarm Systems to perform their intended functions for not less than 1 hour after the start of a fire.

The second gap (SF1-5) is related to the requirement that the fire protection water pumping system consist of at least one diesel-engine-driven fire pump and one electric-motor-driven fire pump set. At Pickering 1,4 the Fire Protection System water supply is fed by four diesel driven fire pumps installed in the Pickering 1,4 Screenhouse. At Pickering 5-8, the Fire Protection System water supply is fed by the station's High Pressure Service Water System powered by Class III and Class IV Electrical Power System [NA44-OM-014-71400-05 R018, Section 5.1, and NK30-OM-058-71400-03, R022, Section 3.4.1]. While normally isolated from each other, the Fire Protection Ring headers can be interconnected if required.

The third gap (SF1-3) is related to the requirement that a display and control centre be located in the Main Control Room and capable of providing detailed information on the location and nature of the signal.

SECTION 4 - GI-48 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	3	N/A	**3**	3	N/A	N/A	N/A	N/A	N/A	N/A	**3**	**3**

Rationale:

This Global Issue relates to the CSA N293-12 standard on fire protection. There is one Acceptable Deviation related to electrical conductors, one Resolution Statement to interconnect the firewater systems of Units 1,4 and 5-8, and an Acceptable Deviation related to annunciation and display.

Regarding deterministic considerations, the relevant safety function is fire protection, but the gaps do not impair the capability to terminate a fire event. Therefore, Defence in Depth (E1) is applicable and the Safety Significance Level is 3 based on row 3 of the first column of Table E1 in the PSR2 Basis Document. Safety Significance Levels (E2) is not applicable because the gaps relate to a defence-in-depth barrier. Therefore, a Safety Significance Level of 3 is selected for deterministic considerations.

For probabilistic considerations, the Probabilistic Safety Assessment includes fire events, and the impact on Core Damage Frequency (F1) is expected to be small, in the range 10^{-7}/y to 10^{-6}/y. Therefore, Safety Significance Level 3 is assigned. Defence in Depth (F2) is not impacted, nor is Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) or Environment (F7). Therefore, the Safety Significance Level is 3 for probabilistic considerations.

In summary, the overall Safety Significance Level is 3. Work is in progress by OPG to address the firewater interconnection.

SECTION 5 - GI-48 RESOLUTION PLAN

GI-48-RS1	Provide, as necessary, design and/or operational changes and commissioning/testing to facilitate required interconnection of Pickering 1,4 and Pickering 5-8 Fire Protection System water supplies to meet the safety intent of CSA N293-12 Clause 7.3.2.2 (d). (SF1-5)
GI-48-AD1	An assessment of this gap (SF1-4) was completed [P-CORR-03680-0620819, *Re: Resolution Plan for Pickering Periodic Safety Review 2 (PSR2) Global Issue #GI-*

SECTION 5 - GI-48 RESOLUTION PLAN	
	48 Gap SF1-4, June 20, 2017]. There is some credit taken in the Fire Safe Shutdown Assessments for fire detection by the Pyrotronics-based automatic detection systems, for some rooms at Pickering NGS. The assessment concluded that the characteristics of the detection/alarm system (detection prior to potential alarm system fire damage, and signal latching function) as well as the physical separation in the equipment/cabling configuration, ensure that lack of a one hour fire rating for cabling in these systems would not cause failure to detect the fire or loss of the fire signal once detected. As such, manual suppression of the fire by Emergency Response Team personnel would not be impeded and there is no adverse nuclear safety impact. This is a low safety significance issue (Safety Significance Level 3) and has been addressed to the extent practicable. Therefore, it is assessed as an Acceptable Deviation. (SF1-3) (SF1-4)
GI-48-AD2	An assessment of this gap (SF1-3) was completed [P-CORR-03680-0620820, *Re: Resolution Plan for Pickering Periodic Safety Review 2 (PSR2) Global Issue #GI-48 Gap SF1-3*, June 2, 2017]. The assessment identified that fire detection and manual fire suppression has some nuclear safety credit at Pickering 1,4. It also confirmed that the existing arrangement of annunciation/display (including a Fire Control Panel located immediately outside the Main Control Room (MCR) and annunciation within the MCR), together with emergency response protocols and staff training, meets the intent of the requirement in providing timely response to fire signals. This is a low safety significance issue (Safety Significance Level 3) and has been addressed to the extent practicable. Therefore, it is assessed as an Acceptable Deviation. (SF1-3)

B.49. GI-49 FFS of Primary Heat Transport Auxiliary Piping Systems, and Primary Heat Transport Valves

SECTION 1 - GI-49 GLOBAL ISSUE SUMMARY

The goal of GI-49, FFS of Primary Heat Transport Auxiliary Piping Systems, and Primary Heat Transport Valves, is to ensure that the Primary Heat Transport auxiliary piping system and pump discharge and boiler inlet and outlet valves remain fit for service for the extended operating period. This Global Issue comprises one Cross-Reference to GI-8 which addresses one COP Review Gap. GI-49 is Safety Significance Level 2 based on deterministic and probabilistic defence-in-depth considerations as well as plant operability considerations.

The proposed Resolution Plan for GI-49 cross-references one of the proposed Resolution Statements for GI-8, Completion/Updating of the Condition Assessments, to complete and update the Condition Assessments for the Primary Heat Transport auxiliary piping system and pump discharge and boiler inlet and outlet valves. Completion of the proposed Resolution Plan will support and strengthen defence-in-depth Level 1.

Safety Significance Level:	2	**Category:**	Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-49 ASSOCIATED GAPS

COP-24	A review for extended operation has not been performed of the inspection results for areas susceptible to wall thinning, high stress areas of the Primary Heat Transport auxiliary piping system, and Primary Heat Transport pump discharge and boiler inlet and outlet valves for Pickering Units 1,4 and 5-8. ***Pickering PSR2 gap COP-24*** **Associated Resolutions:** GI-8-RS1

SECTION 3 - GI-49 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue contains one COP Review Gap related to FFS of Primary Heat Transport auxiliary piping systems and Primary Heat Transport pump discharge and boiler inlet and outlet valves.

CNSC staff has accepted the thickness measurement and inspection of pump discharge and boiler inlet/outlet valves [NK30-PLAN-00531-00001 R005, *Pickering 5-8 Continued Operations Plan*, November 24, 2015; Appendix A, Item 67].

The Primary Heat Transport Piping System is a part of the N285.4 inspection scope. Furthermore, OPG is in the process of updating Condition Assessments in support of extended operation.

SECTION 4 - GI-49 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	2	N/A	**2**	4	2	4	2	N/A	N/A	N/A	**2**	**2**

Rationale:

Addressing this Global Issue assures the ongoing fitness for service of Primary Heat Transport auxiliary piping systems and Primary Heat Transport valves for the operational life of the station. As discussed in Section 3 of this Global Issue, OPG is completing the Condition Assessments to demonstrate that these components are fit for service for the extended operating period.

Nevertheless, this Global Issue has Safety Significance Level 2 for deterministic considerations with respect to Defence in Depth (E1) because addressing it will assure the effectiveness of the pressure boundary barrier (second row of Table E1 in the PSR2 Basis Document). The E2 Safety Significance Level for this Global Issue is considered not applicable because this Global Issue potentially impacts on a nuclear safety barrier, whereas E2 primarily relates to issues that impact other objectives or that are indirectly related to nuclear safety. Hence, the overall Safety Significance Level of 2 for deterministic considerations is dictated by the E1 categorization.

With respect to probabilistic considerations, the auxiliary piping systems interface with the Primary Heat Transport safety barrier, the effectiveness of which can potentially be impacted by a postulated initiating event of frequency is less than 10^{-3}/y. Consistent with Table F2 in the PSR2 Basis Document, the issue has Safety Significance Level 2 for Defence in Depth (F2). Similarly, the Safety Significance Level with respect to Plant Operability is 2, since an extended period of plant shutdown as a result of fitness for service issues of these components is expected to have a probability less than 0.1.

A Safety Significance Level of 4 is assigned for Reactor Safety – Core Damage Frequency (F1). Potential failure of these components is accounted for in the Probabilistic Safety Assessment, and resolution of this Global Issue will ensure that the assumptions in the Probabilistic Safety Assessment regarding the components failure frequency remain valid. Therefore, the change in the Core Damage Frequency will be less than 10^{-7}/y, which corresponds to the fourth row of Table F1 in the PSR2 Basis Document, for which the Safety Significance Level is 4.

With respect to Public Radiation Safety (F3), the radiological consequences of a postulated failure of these components are already accounted for in the safety analysis and shown to be within regulatory

SECTION 4 - GI-49 PRIORITY DETERMINATION
limits. Therefore, this Global Issue will result in no adverse change in Public Radiation Safety (F3), which is the determining factor for the applicability of this consideration. This Global Issue has no direct impact on the other probabilistic considerations, i.e., Occupational Radiation Safety (F5), Emergency Preparedness (F6) and Environment (F7). Therefore, these probabilistic considerations are not applicable. In summary, both deterministic and probabilistic considerations dictate that this Global Issue has a Safety Significance Level of 2. As noted, OPG is completing the Condition Assessments of these components to ensure their fitness for service for extended operation.

SECTION 5 - GI-49 RESOLUTION PLAN	
GI-49-XRF-GI-8-RS1	Complete Condition Assessments for the Primary Heat Transport auxiliary piping system and Primary Heat Transport pump discharge and boiler inlet and outlet valves for Pickering Units 1,4 and 5-8. (COP-24)

B.50. GI-50 N285.4 PIP / Documentation Revision

SECTION 1 - GI-50 GLOBAL ISSUE SUMMARY					
The goal of GI-50, N285.4 PIP/Documentation Revision, is to demonstrate conformance with CSA N285.4, Periodic Inspection of CANDU Nuclear Power Plant Components. This Global Issue comprises two proposed Resolution Statements and one item requiring No Further Action, which address six SF4 Gaps identified from a code review of CSA N285.4-14, and one SF2 Additional Gap. GI-50 is Safety Significance Level 3 based on deterministic safety significance levels considerations. The proposed Resolution Plan for this Global Issue comprises activities to revise OPG's Periodic Inspection Plans and governing documentation to align with elements of the 2014 version of CSA N285.4. These activities address five of the six SF4 Gaps. The remaining SF4 Gap is assessed as requiring No Further Action as it is already addressed by existing OPG governance. The proposed Resolution Plan also includes an activity to assess the impact of extended operation on concessions against CSA N285.4. This activity addresses the SF2 Additional Gap. Completion of the proposed Resolution Plan will support and strengthen defence-in-depth Level 1.					
Safety Significance Level:	3	**Category:**	Programmatic	**Reassessment Beyond 2024:**	N

SECTION 2 - GI-50 ASSOCIATED GAPS	
SF4-3	N285.4 PIP Governance references N285.4-05, not N285.4-09 including Updates 1 and 2. This (programmatic) Darlington gap is a PSR2 gap against N285.4-09 including Updates 1 and 2. ***Code Review N285.4-14*** **Associated Resolutions:** GI-50-RS1
SF4-4	There has been a significant change in the wording of clause 4.2.7 in CSA N285.4-09 including Updates 1 and 2. I-PROC-AS-0009, *Inspection Qualification of Non-Destructive Examination Processes* does not identify the authorized inspector as a qualifying authority as directed by clause 4.2.7. Instead it establishes the CANDU Inspection Qualification Bureau as the organization that would approve procedures and personnel. This (programmatic) Darlington gap is a PSR2 gap against N285.4-09 including Updates 1 and 2. ***Code Review N285.4-14*** • **Note – Per GI-50-NFA1, this gap has been fully addressed.** **Associated Resolutions:** GI-50-NFA1
SF4-5	New erosion and corrosion inspection requirements in N285.4-09 including Updates 1 and 2 are not reflected in current PIP governance. NK38-REP-03680-10137 R000 states that: "It should be noted specifically that [this ISR Issue] is likely to have a major impact on piping PIPs because sub-clauses 7.4.7.X in CSA N285.4-09 including UPD1 and UPD2 include

SECTION 2 - GI-50 ASSOCIATED GAPS	
	substantive changes. Under the new standard erosion and corrosion inspection exemptions can no longer be justified on the basis of [sic] that conditions are determined to be non-erosive and non-corrosive." This Darlington PIP gap will also need to be addressed in the Pickering PIPs. Therefore, this is a PSR2 gap against N285.4-09 including Updates 1 and 2. ***Code Review N285.4-14*** **Associated Resolutions:** GI-50-RS1
SF4-6	Extended life inspection schedules in N285.4-09 including Updates 1 and 2 are not reflected in PIP governance. This (programmatic) Darlington gap is a PSR2 gap against N285.4-09 including Updates 1 and 2. ***Code Review N285.4-14*** **Associated Resolutions:** GI-50-RS1
SF4-7	An assessment of the prior operating non-conforming state, as required by N285.4-09 including Updates 1 and 2, is required when dispositioning inspection results. This requirement has not been included in the Feeder PIP plan. This Darlington PIP gap will also need to be addressed in the Pickering PIPs. Therefore, this is a PSR2 gap against N285.4-09 including Updates 1 and 2. ***Code Review N285.4-14*** **Associated Resolutions:** GI-50-RS1
SF4-8	There is a PSR2 gap for Pickering NGS against N285.4-14 to address: • Revised requirements for pressure tube volumetric and dimensional inspection (Clause 12.2), pressure tube hydrogen equivalent determination (Clause 12.3) and pressure tube material property testing (Clause 12.4); • Clause 12.5 which specifies minimum annulus spacer surveillance examination and testing requirements; • Selection criteria for identifying candidate tube for pressure tube surveillance examination and testing (Annex E) to include selection criteria for annulus spacer surveillance examination and testing; and • Clause 7.4.8 which specifies requirements for inspection of Environmentally Assisted Cracking, and Clauses 7.5.1/7.5.2 which specify requirements for inspection of identical components. ***Code Review N285.4-14*** **Associated Resolutions:** GI-50-RS1
SF2-AG10	An SF2 Gap related to a review of program implementation concessions for CSA N285.4 for extended operation was identified in [P-CORR-00531-05099, e-Doc 5295534, July 12, 2017]. **Associated Resolutions:** GI-50-RS2

SECTION 3 – GI-50 BACKGROUND INFORMATION AND RESOLUTION STRATEGY

This Global Issue consists of seven Gaps. Six of these Gaps are Darlington programmatic gaps against CSA N285.4-14 which are applicable to PSR2, and the seventh gap is an Additional Gap related to an assessment of the applicability of previous concessions on N285.4-14 with respect to extended operation. OPG has unit-specific Periodic Inspection Plans (PIPs) in place to support CSA N285.4 compliance. The Pickering NGS Licence Conditions Handbook currently requires OPG to comply with the requirements of the 2005 version of the standard.

SECTION 4 – GI-50 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								Overall Safety Significance Level
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	
	N/A	3	**3**	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**	**3**

Rationale:

This Global Issue consists of gaps related to CSA N285.4-14. OPG has unit-specific Periodic Inspection Plans in place to support CSA N285.4 compliance. Resolution of this Global Issue will result in updates to the N285.4 Periodic Inspection Plan, governance and Fuel Channel inspection and surveillance requirements.

Regarding deterministic considerations, this Global Issue is not directly applicable to Defence in Depth (E1). The issue is assigned Safety Significance Level 3 for E2 on the basis that the issue is not significant. This is because, as discussed in Section 5 of this Global Issue, the N285.4 Periodic Inspection Plans and governance are currently in compliance with the 2005 version of the standard and the revisions are not significant. Hence, the overall Safety Significance Level of 3 for deterministic considerations is dictated by the E2 categorization.

For probabilistic considerations, this Global Issue has no impact on Core Damage Frequency (F1) or Defence in Depth (F2), nor does it impact Public Radiation Safety (F3), Plant Operability (F4), Occupational Radiation Safety (F5), Emergency Preparedness (F6) or Environment (F7). Therefore, probabilistic considerations are not applicable.

In summary, the overall Safety Significance Level for this Global Issue is 3.

SECTION 5 – GI-50 RESOLUTION PLAN	
GI-50-RS1	Revise the CSA N285.4 PIPs and governance to align with elements of N285.4-14, including making reference to CSA N285.4-14, addressing erosion and corrosion inspection requirements, reflecting extended life inspection schedules, and addressing assessment of the prior non-conforming state when dispositioning inspection results. (SF4-3) (SF4-5) (SF4-6) (SF4-7) (SF4-8)
GI-50-RS2	Assess the impact of extended operation on concessions against CSA N285.4. (SF2-AG10)
GI-50-NFA1	Clause 4.2.7 of CSA N285.4-09 Update 2 states, *"Procedures satisfying the requirements of Clause 4.2.2 that are used to detect and characterize in-service degradation or manufacturing flaws shall be demonstrated to the satisfaction of the authorized inspector".* OPG is in compliance with this requirement as Section 1.4.2 of OPG Procedure [I-PROC-AS-0002-R009, *Technical Document Control*, May 19, 2016], requires demonstration to the Authorized Nuclear Inspector (ANI) of all Non-Destructive Examination (NDE) pressure boundary related procedures for those NDE activities involving volumetric methods in support of CSA standards N285.4 and N285.5 or as required by the CNSC. This is required for any revision or change to authorized procedures, or whenever requested by the CNSC and/or the ANI. No further action is required. (SF4-4)

B.51. GI-51 Fuelling with Pressure Tube Sag

SECTION 1 - GI-51 GLOBAL ISSUE SUMMARY					
The goal of GI-51, Fuelling with Pressure Tube Sag, is to address a Gap identified by the Expert Panel related to the impact of Pressure Tube sag on the ability to fuel for the duration of extended operation. This Global Issue comprises one No Further Action item addressing the Expert Panel gap. GI-51 is Safety Significance Level 4 based on deterministic defence-in-depth considerations. The Expert Panel Gap is assessed as requiring no further action based on the Pickering EFPH and the predicted Pressure Tube sag.					
Safety Significance Level:	4	**Category:**	Engineering, Analytical	**Reassessment Beyond 2024:**	Y

SECTION 2 - GI-51 ASSOCIATED GAPS	
EP-1	The Expert Panel review of the Global Issues identified that it was not apparent that the impact of Pressure Tube sag on the ability to fuel the channels for the period of extended operation had been considered. **Associated Resolutions:** GI-51-NFA1

SECTION 3 - GI-51 BACKGROUND INFORMATION AND RESOLUTION STRATEGY
This Global Issue contains one Expert Panel Gap related to the impact of Pressure Tube sag on the ability to fuel for the duration of extended operation. The impact of Pressure Tube sag on the ability to fuel the Fuel Channels for the period of extended operation is assessed by comparing the Pickering EFPH and the associated predicted Pressure Tube sag for the extended operating period to the EFPH values at which the limits for sag on fuelling are predicted to be reached, as documented in the Fuel Channel LCMPs.

SECTION 4 - GI-51 PRIORITY DETERMINATION

Safety Significance of Global Issue	Deterministic Considerations			Probabilistic Considerations								
	E1 – Defence in Depth	E2 – Safety Significance Level	**Overall Deterministic Considerations**	F1 – Reactor Safety – Core Damage Frequency	F2 – Reactor Safety – Defence In Depth	F3 – Public Radiation Safety	F4 – Plant Operability	F5 – Occupational Radiation Safety	F6 – Emergency Preparedness	F7 – Environment	**Overall Probabilistic Considerations**	**Overall Safety Significance Level**
	4	N/A	**4**	N/A	N/A	N/A	4	N/A	N/A	N/A	**4**	**4**

<u>Rationale:</u>

Resolution of this Global Issue will confirm the ability to fuel the Fuel Channels for the period of extended operation. The issue of Pressure Tube sag is included in GI-1, Fitness for Service for Fuel Channels, and GI-4, Fitness for Service for Reactor Components and Structures.

Regarding deterministic considerations, this Global Issue is associated with a physical barrier, so Defence in Depth (E1) is applicable. A Safety Significance Level of 4 is assigned based on the assessment described in the proposed Resolution Plan that Pressure Tube sag will not adversely impact the ability to fuel until after 2024. The E2 Safety Significance Level for this Global Issue is considered not applicable because this Global Issue potentially impacts on a nuclear safety barrier, whereas E2 primarily relates to issues that impact other objectives or that are indirectly related to nuclear safety. Therefore, an overall Safety Significance Level of 4 is selected for deterministic considerations.

With respect to probabilistic considerations, this Global Issue is assigned Safety Significance Level 4 for Plant Operability (F4) since it may to lead to some loss of operating margin if Pressure Tube sag is more than expected. This Global Issue has no direct impact on the other probabilistic factors, i.e., Core Damage Frequency (F1), probabilistic Defence in Depth (F2), Public Radiation Safety (F3), Occupational Radiation Safety (F5), Emergency Preparedness (F6) or Environment (F7). Therefore, these probabilistic considerations are not applicable.

In summary, the overall Safety Significance Level is 4.

SECTION 5 - GI-51 RESOLUTION PLAN

GI-51-NFA1	The extent of and the acceptable limits for Pressure Tube (PT) sag on fuelling are documented in the Pickering Fuel Channel Life Cycle Management Plan (LCMP) references for Pickering 1,4 [NA44-REP-31100-00089-R000, *Status of Degradation Mechanisms for Pickering Units 1&4 as of December 2016 –*

SECTION 5 - GI-51 RESOLUTION PLAN	
	Summary for Fuel Channel Life Cycle Management Plan, May 19, 2017] and Pickering 5-8 [NK30-REP-31100-10188-R000, *Status of Degradation Mechanisms for Pickering 5-8 as of December 2016 – Summary for Fuel Channel Life Cycle Management Plan*, February 28, 2017]. In these reports, linear regression of in-service Pressure Tube sag measurements is used to predict Pressure Tube sag as a function of EFPH. In [P-CORR-31100-00007, *Pickering NGS – Fuel Channel Fitness-for-Service Risk Assessment – Impact of mid-2017 Planning Assumptions*, August 22, 2017], the EFPHs at 2024 are estimated for each unit. Based on the EFPHs, fuel bundle passage is assured for all Pickering Units up to 2024. The acceptability of the degree of Pressure Tube sag will be updated as required, as part of the regular updates of the LCMPs. Therefore no further PSR2 action is required for ensuring the ability to fuel at Pickering with Pressure Tube sag up to 2024. (EP-1)

Appendix C – Ranking of Proposed Resolution Statements

C.1. Introduction

Ranking of Global Issues with identified actions is the seventh element of the Global Assessment process, as listed in Section 3.3.2 of the PSR2 Basis Document [P-REP-03680-00001-R002, *Pickering NGS Periodic Safety Review 2 (PSR2) Basis Document*, June 2016]. This appendix describes the method for performing this ranking and presents the ranking results. The method is applied to Global Issue proposed Resolution Statements that have identified actions. Acceptable Deviations and No Further Action statements do not go through the ranking process.

Section C.2 describes the factors that are taken into account when defining the ranking methodology. Section C.3 describes the Value Tree methodology that is used for the ranking process. Section C.4 develops the Value Tree for PSR2. Sections C.5 and C.6 present the results of the ranking methodology steps, and Section C.7 presents the ranked proposed Resolution Statements.

C.2. Ranking Process Description and Approach

The prioritized Global Issues and their proposed Resolution Statements (refer to Appendix B) are the inputs to the ranking process described in this appendix. The purpose of ranking proposed Resolution Statements is to determine the activities that will be most effective in enhancing safety given the limited extended operating period of the plant. The ranking process recognizes that there are many factors that have to be taken into account in determining the rank of a specific proposed Resolution Statement, but a key consideration is that the ranking takes place within the context of the specific time period related to extended operation. Activities that will take a relatively long time to implement or to take effect may have relatively little practical benefit if the subsequent period of operation is short.

The PSR2 ranking process, which determines the relative merit of a number of potentially competing actions based on a variety of considerations, is a multi-attribute decision process. Such processes are typically addressed through a method known as a Value Tree, which is described in the next sub-section.

C.3. The Value Tree Method

The relative merit of implementing the proposed Resolution Statement of a Global Issue depends on the degree to which it contributes to the overall objective of PSR2, which is to determine reasonable and practicable enhancements that may be made to support continued safe operation. To aid in determining the degree to which each proposed Resolution Statement will contribute to the overall objective, relative to the contributions of the other proposed Resolution Statements, the overall objective is divided into a number of sub-objectives against which the merits of the proposed Resolution Statements are assessed.

The Value Tree for PSR2 is a representation of the overall objective and its sub-objectives arranged in a hierarchy. At the highest level or "trunk" of the tree there is a single *overall* objective. The branches of the tree consist of six *fundamental* objectives that contribute directly to the overall objective. Each fundamental objective is characterized in terms of a measurable attribute that is used to determine the degree to which a proposed Resolution Statement accomplishes the fundamental objective.

The Value Tree is used in the following manner:

- Each fundamental objective is assigned a weight that denotes the importance of the associated objective in contributing to the overall objective, relative to the other fundamental objectives. Weights are assigned to each fundamental objective using the Pairwise Comparison method. This method was devised by Thomas L. Saaty for his Analytic Hierarchy Process [Saaty, T. L., *Decision Making with the Analytic Hierarchy Process*, International Journal of Services Sciences, Vol. 1, No. 1, 2008]. This method has been successfully used in previous PSRs to rank multiple, potentially competing actions. The determination of objective weights is described in Section C.5.
- Each proposed Resolution Statement is matched to the most relevant fundamental objective, and a score (referred to as the utility) is assigned to the proposed Resolution Statement to indicate the degree to which the outcome of implementing it will address the fundamental objective. Each score is derived by applying a utility function that takes into account the time it will take to implement a proposed Resolution Statement and the benefit it will have once implemented. This method is based on utility theory as originally developed in the field of micro-economics. This approach is used in the Pickering NGS PSR2 process, as it has been used in previous PSRs and because the nature of the proposed Resolution Statements for PSR2 is similar to enhancement actions identified in previous PSRs. The utility scoring method is described in Section C.6.
- The overall ranking score of each specific proposed Resolution Statement is calculated as the product of the objective weight and the utility. The results are presented in Section C.7.

Proposed Resolution Statements with the highest ranking scores contribute to the fundamental objective to a greater degree than those with lower ranking scores.

C.4. The Pickering PSR2 Value Tree

The overall objective for PSR2 is stated as follows:

> *Enhance confidence in the continued safe operation of Pickering NGS for the period of PSR2.*

Development of the Value Tree starts with consideration of the 15 Safety Factors of PSR2. This is helpful since Global Issues can for the most part be associated with a single Safety Factor. Experience has shown that six to eight fundamental objectives is a good practical number to use in the Value Tree methodology. The 15 Safety Factors are, therefore, grouped to formulate fundamental objectives. The starting point is the five groupings used by IAEA SSG-25 [IAEA Specific Safety Guide SSG-25, *Periodic Safety Review of Nuclear Power Plants*, March 2013] for its 14 Safety Factors plus the additional Safety Factor on Radiation Protection prescribed by CNSC REGDOC-2.3.3 [CNSC Regulatory Document REGDOC-2.3.3, *Periodic Safety Reviews*, April 2015], which is grouped with the fourteenth Safety Factor from SSG-25. The result is presented in Table 22.

Table 22: Safety Factor Groupings According to SSG-25 and CNSC REGDOC-2.3.3

SF#	Title
Safety factors relating to the plant	
1	Plant design
2	Actual condition of structures, systems and components (SSCs) important to safety
3	Equipment qualification
4	Aging
Safety factors relating to safety analysis	
5	Deterministic safety analysis
6	Probabilistic safety assessment
7	Hazard analysis
Safety factors relating to performance and feedback of experience	
8	Safety performance
9	Use of experience from other plants and research findings
Safety factors relating to management	
10	Organization, the management system and safety culture
11	Procedures
12	Human factors
13	Emergency planning
Safety factors relating to the environment and radiation protection	
14	Radiological impact on the environment
15	Radiation protection

Given the stage in the life-cycle of Pickering NGS it is reasonable to assign SF1 on Design to its own separate group but to keep SF2, SF3 and SF4, which all deal with fitness for service, together in their own group. That is because design changes to the plant at this stage in its life cannot be considered as important as maintaining the fitness for service of the existing equipment. The resultant six Safety Factor groups are:

- Safety Factors relating to plant design (SF1);
- Safety Factors relating to fitness for service (SF2, SF3, and SF4);
- Safety Factors relating to safety analysis (SF5, SF6, and SF7);
- Safety Factors relating to safety performance and feedback of experience (SF8 and SF9);
- Safety Factors relating to management (SF10, SF11, SF12, and SF13); and,
- Safety Factors relating to radiation protection and the environment (SF14 and SF15).

The six Safety Factor groups are used as the basis for the fundamental objectives of the Value Tree as illustrated in Figure 3.

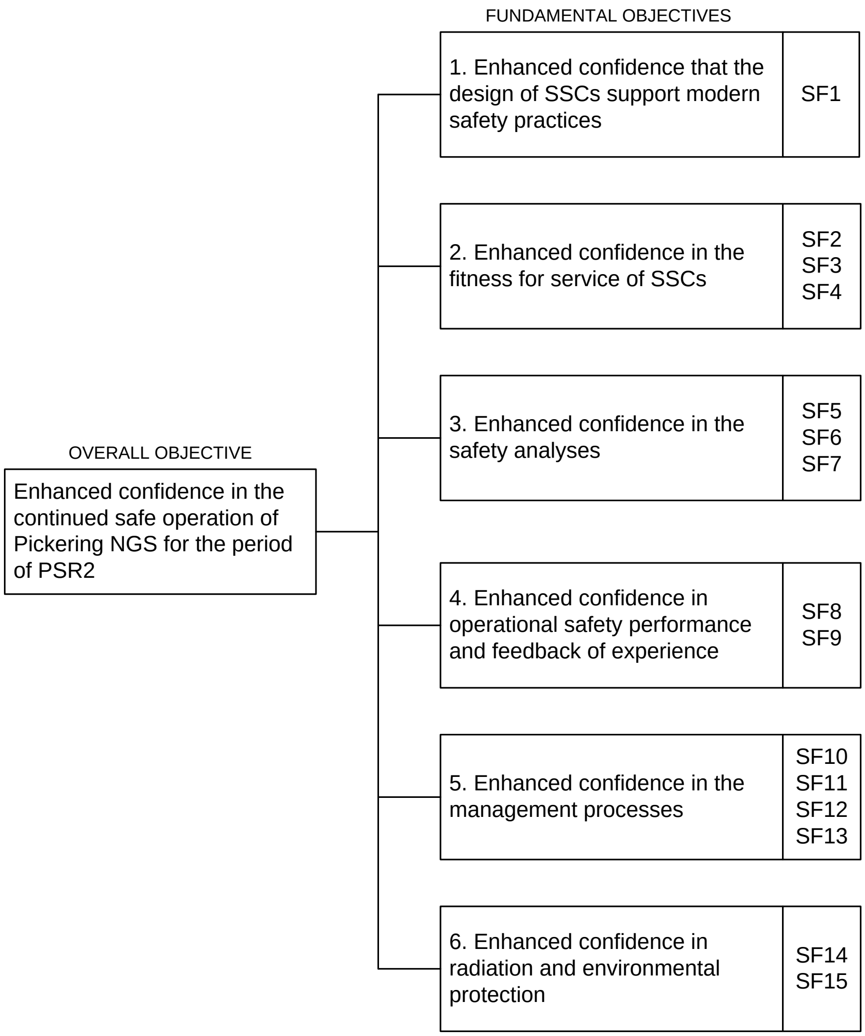

Figure 3: Value Tree for PSR2

C.5. PSR2 Value Tree Objective Weights

The method for assigning the weights to the Value Tree fundamental objectives is the pairwise comparison method used in the Analytical Hierarchy Process as discussed in Section C.3. The process consists of the following steps:

(i) Convene a group of subject matter experts and lead them through a process of using pairwise comparisons to rank all of the fundamental objectives in terms of importance on a scale from 1 to 9, resulting in a 6 x 6 reciprocal matrix;

(ii) Compute the eigenvalues of the matrix and find the eigenvector corresponding to the largest eigenvalue λ_{max};

(iii) Normalize the largest eigenvector and decompose it into its 6 components;

(iv) Assign the components of the normalized eigenvector as weights to the corresponding objectives on the Value Tree;

(v) Compute the consistency index (CI) as CI = $(\lambda_{max} – n) / (n – 1)$ where n=6; and

(vi) Compute the consistency ratio (CR), as the ratio of the CI for a particular set of judgments, to the random index (RI) for a matrix of the same size as published by Saaty. If CR is less than 10%, the judgment results are considered acceptable.

The importance scale used in the first step of the pairwise comparison process is given in Table 23.

Table 23: Pairwise Comparison Intensity of Importance Scale

Intensity of Importance	Definition	Explanation
1	Equal Importance	Two actions contribute equally to the objective
2	Weak or slight	-
3	Moderate importance	Experience and judgement slightly favour one action over another
4	Moderate plus	-
5	Strong importance	Experience and judgement strongly favour one action over another
6	Strong plus	-
7	Very strong or demonstrated importance	An action is favoured very strongly over another; its dominance demonstrated in practice
8	Very, very strong	-
9	Extreme importance	The evidence favouring one action over another is of the highest possible order of affirmation
Reciprocals of above	If action *i* has one of the above non-zero numbers assigned to it when compared with action *j*, then *j* has the reciprocal value when compared with *i*	A reasonable assumption
1.1–1.9	If the actions are very close	May be difficult to assign the best value but when compared with other contrasting actions the size of the small numbers would not be too noticeable, yet they can still indicate the relative importance of the activities.

The subject matter expert group compared all pair combinations of fundamental objectives in terms of their relative importance in contributing to the overall objective using the scale shown in

Table 23. When assigning relative importance to a fundamental objective, the following were taken into account:

- Issues relating to fitness for service and aging management are more important than the other issues;
- Issues involving conformance with modern design standards and nuclear safety analysis standards are of less importance given the limited timeframe of extended operation; and
- Pickering NGS has mature management processes as well as environmental and radiation practices. Issues involving marginal improvements to these practices are therefore less important.

The pairwise comparisons are documented in Table 24 for each pair of objectives (X, Y). If objective X was favoured over Y, the number associated with the strength of relative importance from the table above was inserted in the Favour X column. If Y was favoured over X the number was inserted in the Favour Y column. The Basis column provides the rationale for the assessment.

Table 24: Pairwise Comparison

Favour X	Objective X	Objective Y	Favour Y	Basis
-	1. Enhanced confidence in the design of SSCs	2. Enhanced confidence in the fitness for service of SSCs	2	Both objectives are, in principle, of similar importance for supporting continued safe operation. Given that the proposed continued operation is for a limited period, the practicality of making design changes is generally limited, and therefore taking actions necessary to ensure confidence in the fitness for service (FFS) of SSCs are considered the more important actions for ensuring safe operation. Accordingly, FFS of SSCs is considered to be somewhat more important than design changes that would be implemented for the purpose of enhancing conformance with the requirements of new codes and standards.
-	1. Enhanced confidence in the design of SSCs	3. Enhanced confidence in the safety analyses	2	Both objectives are, in principle, of similar importance for supporting continued safe operation. Enhanced confidence in the safety analyses of the actual aged conditions of the plant is somewhat more important in comparison to introducing design changes for the purpose of enhancing conformance with the requirements of new codes and standards. This is in particular true given that the proposed continued operation is for

Favour X	Objective X	Objective Y	Favour Y	Basis
				a limited period.
2	1. Enhanced confidence in the design of SSCs	4. Enhanced confidence in safety performance and feedback of experience	-	Consideration of lessons learned from CANDU Owners Group (COG) and international Operating Experience in operating plants is important in ensuring safe operation of Pickering NGS. However, introducing practicable design modifications can significantly contribute to enhancing the confidence in continued safe operation by demonstrating conformance with modern codes and standards. Hence, enhanced confidence in design is somewhat more important in comparison to incorporating feedback of lessons learned and/or OPEX.
2	1. Enhanced confidence in the design of SSCs	5. Enhanced confidence in the management processes	-	The management and governance of Condition Assessments, periodic inspections and updates of life cycle management plans is important for ensuring FFS of safety significant SSCs and play an important role in maintaining safe operation. However, given the maturity of the Pickering NGS management processes this is somewhat less important than introducing design changes for the purpose of enhancing conformance with the requirements of new codes and standards.
2	1. Enhanced confidence in the design of SSCs	6. Enhanced confidence in the radiation and environmental protection	-	Regulatory and public expectations with respect to maintaining progressively lower radiological releases and environmental impact continue to be a prominent topic. In addition, the recent OPEX from the 2011 Fukushima accident resulted in the implementation of initiatives that are designed to minimize potential releases and environmental impacts of BDBAs. However, radiation and environmental practices at Pickering NGS are mature and successful. Allocating additional resources to marginally improve the capability to maintain a low environmental impact under normal operating conditions, as well as emergencies, is therefore somewhat less important than enhanced confidence in the design basis of the SSCs.
2	2. Enhanced confidence in the fitness for service of -	3. Enhanced confidence in the safety analyses	-	In considering extended plant operation, FFS of SSCs to ensure their continued functional capability is considered to be important for safe and reliable operation. Similarly, the plant safety case must be demonstrated based on modeling

Favour X	Objective X	Objective Y	Favour Y	Basis
	SSCs			the actual configuration and condition of the plant by considering the planned extended operating period to maintain safety margins. However due to its direct impact, FFS of SSCs is judged to be somewhat more important than safety analysis.
2	2. Enhanced confidence in the fitness for service of SSCs	4. Enhanced confidence in safety performance and feedback of experience	-	In considering extended plant operation, FFS of SSCs to ensure their continued functional capability is considered to be important for safe and reliable operation. Consideration of lessons learned from COG and international Operating Experience in operating plants is also important in ensuring safe operation, however due to its more direct impact, FFS of SSCs is considered somewhat more important in comparison with OPEX feedback.
2	2. Enhanced confidence in the fitness for service of SSCs	5. Enhanced confidence in the management processes	-	In considering extended plant operation, FFS of SSCs to ensure their continued functional capability is considered to be important for safe and reliable operation. The management and governance of Condition Assessments, periodic inspections and updates of Life Cycle Management Plans are also important for ensuring FFS of safety significant SSCs and accordingly play an important role in maintaining safe operation. However due to its more direct impact, FFS of SSCs is considered somewhat more important in comparison with the confidence in management processes.
3	2. Enhanced confidence in the fitness for service of SSCs	6. Enhanced confidence in the radiation and environmental protection	-	In considering extended plant life, FFS of SSCs to ensure their continued functional capability is considered to be important for safe and reliable operation. Improving the capability to maintain a low environmental impact under normal operating conditions, as well as emergencies, is also important. However, the direct impact of FFS is a moderately more important factor because of its role in ensuring event-free operation, which would lead to reducing the risk of radiological releases and any impact on the environment.
2	3. Enhanced confidence in the safety	4. Enhanced confidence in safety performance	-	The plant safety case is demonstrated based on modeling the actual configuration and condition of the plant by considering the planned extended operation to maintain safety margins. It is also

Favour X	Objective X	Objective Y	Favour Y	Basis
	analyses	and feedback of experience		important to consider lessons learned from COG and international operating experience in operating plants, however, the safety analysis of the actual plant conditions is somewhat more important in comparison to consideration of OPEX.
2	3. Enhanced confidence in the safety analyses	5. Enhanced confidence in the management processes	-	The plant safety case is demonstrated based on modeling the actual configuration and condition of the plant by considering the planned extended life to maintain safety margins. The safety analysis of the actual plant conditions is deemed somewhat more important in comparison to marginal improvements in already mature management processes.
2	3. Enhanced confidence in the safety analyses	6. Enhanced confidence in the radiation and environmental protection	-	The plant safety case is demonstrated based on modeling the actual configuration and condition of the plant by considering the planned extended operation to maintain safety margins. Improving the capability to maintain a low environmental impact under normal operating conditions, as well as emergencies, is also important, however, demonstrating that the safety margins are maintained also contributes to enhancing the confidence in the radiation and environmental protection and, overall, is somewhat more important than enhancing the confidence in already mature radiation and environmental protection practices.
2	4. Enhanced confidence in safety performance and feedback of experience	5. Enhanced confidence in the management processes	-	Consideration of lessons learned from COG and international operating experience in operating plants is important in ensuring safe operation of Pickering NGS. This is considered to have a relatively more direct impact on and is somewhat more important for the enhanced confidence in extended operation than enhancing confidence in the management processes.
2	4. Enhanced confidence in safety performance and feedback of experience	6. Enhanced confidence in the radiation and environmental protection	-	Consideration of lessons learned from COG and international operating experience in operating plants is important in ensuring safe operation of Pickering NGS. Demonstrating that such feedback is considered in the safety case would play an important role in ensuring that the risk of radiological releases and environmental impact is not increased due to extended operation. This is

Favour X	Objective X	Objective Y	Favour Y	Basis
				considered to have a somewhat more important impact than enhancing confidence in the already mature radiation and environmental protection practices.
2	5. Enhanced confidence in the management processes	6. Enhanced confidence in the radiation and environmental protection	-	The management and governance of Condition Assessments, periodic inspections and updates of life cycle management plans are important for ensuring FFS of safety significant SSCs and accordingly play an important role in maintaining safe operation. Enhancing the confidence in the management processes, in particular those relevant to FFS of SSCs, has a contribution in enhancing the confidence that Pickering NGS will ensure safety margins during the extended operating period, which also contributes to enhancing the confidence in the radiation and environmental protection practices and, overall, is somewhat more important than enhancing confidence in the already mature radiation and environmental protection practices.

The matrix resulting from the pairwise comparison process is shown in Table 25.

Table 25: Objective Weights Matrix

		1	2	3	4	5	6
		Enhanced confidence that the design of SSCs support modern safety practices	Enhanced confidence in the fitness for service of SSCs	Enhanced confidence in the safety analyses	Enhanced confidence in operational safety performance and feedback of experience	Enhanced confidence in the management processes	Enhanced confidence in the radiation and environmental protection
1	Enhanced confidence that the design of SSCs support modern safety practices	1.00	0.50	0.50	2.00	2.00	2.00
2	Enhanced confidence in the fitness for service of SSCs	2.00	1.00	2.00	2.00	2.00	3.00
3	Enhanced confidence in the safety analyses	2.00	0.50	1.00	2.00	2.00	2.00
4	Enhanced confidence in operational safety performance and feedback of experience	0.50	0.50	0.50	1.00	2.00	2.00
5	Enhanced confidence in the management processes	0.50	0.50	0.50	0.50	1.00	2.00
6	Enhanced confidence in the radiation and environmental protection	0.50	0.33	0.50	0.50	0.50	1.00

The weight of each of the objectives is obtained by solving for the normalized components of the eigenvector associated with the principal eigenvector of the matrix. The results are as follows:

- Principal Eigenvalue = 6.224;
- Normalized Eigenvector components: 0.172, 0.288, 0.217, 0.136, 0.108, 0.079; and
- The Consistency Ratio of this matrix is 3.61% which is within the acceptance limit of 10%.

Table 26 shows the resultant weights for each of the six fundamental objectives. Enhanced confidence in the fitness for service is the highest ranked objective, followed by Enhanced confidence in the safety analyses. These weights reflect the earlier discussion that issues relating to fitness for service and aging management are more important than the other issues.

Table 26: Fundamental Objective Weight

No.	Fundamental Objective	Weight
1	Enhanced confidence that the design of SSCs support modern safety practices	0.17
2	Enhanced confidence in the fitness for service of SSCs	0.29
3	Enhanced confidence in the safety analyses	0.21
4	Enhanced confidence in operational safety performance and feedback of experience	0.14
5	Enhanced confidence in the management processes	0.11
6	Enhanced confidence in the radiation and environmental protection	0.08

C.6. Assigning Scores to Proposed Resolution Statements

Once the weights for the fundamental objectives in the Value Tree have been determined, each proposed Resolution Statement is assigned to one of the fundamental objectives. The next step is to assign a utility score to the proposed Resolution Statement which reflects the degree to which completing the activities in the proposed Resolution Statement will address the associated objective.

The Utility Function method of scoring is used to account for potential uncertainty in how effective a proposed Resolution Statement may be in terms of addressing its associated fundamental objective, and for potential uncertainty in the time it will take for the benefit to occur. Scores are assigned to proposed Resolution Statements using a two-variable utility function that considers time and impact attributes, as follows:

- The **Time** attribute measures the impact of implementing the proposed Resolution Statement by answering the following question: “How long will it take to implement the resolution and to see the associated objective being realized?”
- The **Impact** attribute measures how directly or strongly the issue impacts the fundamental objective by asking: “If one could somehow resolve the Global Issue immediately (i.e., the proposed Resolution Statement happens overnight), how direct or big would the impact be in terms of realizing the associated objective?”

For ease of use, a discrete and not continuous utility function is used with the input variables associated with the two attributes being assigned a value, using a rating system on a scale of 1 to 5 as presented in Table 27 and Table 28.

Table 27: Rating System for the Time Attribute

Time Rating	Definition
1	Resolving the issue and to have it affect the objective will take at least 5 years
2	Resolving the issue and to have it affect the objective will take 4 to 5 years
3	Resolving the issue and to have it affect the objective will take 3 to 4 years
4	Resolving the issue and to have it affect the objective will take 2 to 3 years
5	Resolving the issue and to have it affect the objective will take 0 to 2 years

Table 28: Rating System for the Impact Attribute

Impact Rating	Definition
1	Resolving the issue will have an indirect and negligible impact on the objective
2	Resolving the issue will have an indirect and minor or incremental impact on the objective
3	Resolving the issue will have a direct and minor or incremental impact on the objective
4	Resolving the issue will have an indirect and major impact on the objective
5	Resolving the issue will have a direct and major impact on the objective

To assist in the assignment of Impact ratings, guidance is provided in the matrix presented in Table 29. Generally, these are maximum values; actual values also take into account the specific nature of the proposed Resolution Statement.

Table 29: Impact Guidance Matrix

Type of Global Issue Resolution Statement			Nature of Improvement in Terms of Barriers and Practices			
			1	2	3	4
			New Barriers and Practices	Augmentation of the Current Barriers and Practices	Improvement of the Current Barriers and Practices	Modernization of Current Barriers and Practices
1	Design Change and Implementation		(5)	(5)	(4)	(3)
2	Improve Operational or Safety Performance – (Fitness for Service Assessment, Maintenance, Configuration Management, Prevention of/Response to Events)		(5)	(5)	(4)	(3)
3	Reduce Uncertainty – (Analysis, Safe Operating Envelope)		(4)	(3)	(2)	(1)
4	Improve Managed System and Organizational Effectiveness- (Process, program, procedure)	a. Field Impact (e.g., operating, outage, maintenance, field procedures)	(4)	(3)	(2)	(1)
		b. Impact on managed system and support processes (e.g., training)	(3)	(2)	(2)	(1)

Notes:

1. Values in parentheses represent guidance for Impact Rating defined in Table 28.
2. “New” means there is no barrier or practice currently in place.
3. “Augmentation” means current barrier is not complete or execution gaps in current practices or the modern codes and standards have complementary requirements that are not currently in place (e.g., FFS assessments to address execution gaps for Major Components is considered as direct and major impact on the objective).
4. “Improvement” means current barriers or practices require additional supporting assessment (e.g., other supporting FFS assessments for SSCs is considered here as major and indirect impact on the objective).
5. “Modernization” means current barriers or practices are effective but documentation and/or practices need to be updated to reflect current trends, state of the art approaches, terminology, etc. with no impact on operational performance (e.g., FFS assessments of non-Major Components is considered as direct and minor impact on the objective).
6. Replacement of any original SSCs is considered as a Design Change.

The characteristics of the impact of resolving the activity (i.e., Direct, Indirect, Major, Minor) are considered within the context of: 1-Design Changes and Implementation, 2-Improving Operational or Safety Performance, 3-Reduction of Uncertainty and 4-Improvement of Enablers to maintain or enhance the safe operation of the plant over the extended operating period. These aspects are considered with respect to their contribution to addition of new barriers, and augmentation, improvement or modernization of current barriers and practices.

Once the time and impact ratings are determined, the utility score for each is determined based on the following utility function:

$$U(x) = 1 - e^{-x/R}$$

Where:

- U is the utility score of attribute x, with $0 < U < 1$
- x is the rating of the attribute on some scale (in this case, the 1 to 5 scale used for Impact and Time ratings).
- R is an adjustable parameter that expresses a judgment about the relative importance of Impact and Time. By adjusting R the utility is more strongly weighted towards solutions with high Impact or Time ratings.

The combined utility of the Time and Impact parameters is determined using the following formula which integrates the utility function discussed above:

$$U(i,t) = k_i\, U_I(i) + k_t\, U_T(t) + (1\text{-}k_i\text{-}k_t)\, U_I(i)U_T(t)$$

Where:

- $U(i,t)$ is the utility score of the proposed Resolution Statement, taking into account the Time and Impact ratings each assessed on a 1 to 5 scale
- k_i is the contribution of the Impact attribute
- $U_I\ = 1 - e^{-i/RI}$
- k_t is the contribution of the Time attribute
- $U_T\ = 1 - e^{-t/RT}$

Consistent with previous PSRs the values for each k and R are:

- k_i = 0.3
- R_I = -5.0
- k_t = 0.1
- R_T = -2.0

The result is the utility matrix given in Table 30. To use the matrix, the Time and Impact ratings are determined on a 1 to 5 scale, and the resulting utility (score) associated with resolving the proposed Resolution Statement is given by the number in the cell associated with the Time and Impact rating.

Table 30: Utility Matrix

		Time				
		1	2	3	4	5
Impact	1	0.00	0.01	0.03	0.05	0.10
	2	0.05	0.08	0.11	0.17	0.26
	3	0.12	0.15	0.21	0.31	0.46
	4	0.20	0.25	0.34	0.48	0.70
	5	0.30	0.37	0.49	0.68	1.00

The matrix introduces a preference towards solutions that:

- Have greater impact on the objective in a shorter time, i.e., (4,4) is 6 times more preferable than (2,2).
- Have larger impact versus one that can be done quickly but with little impact, i.e., (1,5) is three times more preferable than (5,1).

C.7. Ranking Results

The Ranking Value of each proposed Resolution Statement is determined as follows:

- Each proposed Resolution Statement is assigned to one of the fundamental objectives in Table 26 and is given the Weight associated with the fundamental objective shown in the table;
- The Time Rating of the proposed Resolution Statement is determined on a scale of 1 to 5 using Table 27;
- The Impact Rating of the proposed Resolution Statement is determined on a scale of 1 to 5 using Table 28 and Table 29;
- The Impact and Time Ratings are used to read off the Utility Score from Table 30;
- The Ranking Value of the proposed Resolution Statement is calculated by multiplying its Utility Score with its Weight; and
- The resulting ranking is subjected to review and rationalization by the PSR2 Expert Panel and OPG PSR2 Project Staff. This allows for the use of engineering judgment and considerations such as the impact of the ranking on multiple objectives to arrive at a final rank order.

The results of applying the ranking methodology are shown in Table 31. For each proposed Resolution Statement, the associated Value Tree objective is shown, along with the Objective Weight and the values of the Time and Impact attributes, along with the rationale for each. Finally, the Utility Score and Ranking Value are shown.

The results in Table 31 are normalized to 100, and the normalized Ranking Values of the proposed Resolution Statements are shown in decreasing order in Table 18.

Table 31: Global Issue Proposed Resolution Statement Ranking

Global Issue/RS Title	Objective	Objective Weight	Objective Justification	Time Attribute	Time Attribute Justification	Impact Attribute	Impact Attribute Justification	Utility Score	GI-RS Ranking Value
GI-1-RS1 Complete CSA N285.8 Compliance Plan activities, including responding to comments.	2. Enhanced Confidence in the fitness for service of SSCs	0.29	The issue is indirectly related to FFS for Fuel Channels.	5	Issue resolution can occur within 2 years, with immediate impact on the objective.	4	Completing the Compliance Plan activities has an indirect and major impact on the confidence in FFS of Fuel Channels.	0.70	0.203
GI-1-RS2 Review and revise if/as required the CSA N285.4 compliant Periodic Inspection Plans for Fuel Channels for Pickering NGS to cover the extended operating period.	2. Enhanced Confidence in the fitness for service of SSCs	0.29	The issue is indirectly related to FFS for Fuel Channels.	5	Issue resolution can occur within 2 years, with immediate impact on the objective.	4	Completing the PIP has an indirect and major impact on the confidence in FFS of Fuel Channels.	0.70	0.203

GI-9-RS1 Complete the required assessment to support the current fuel basket stacking arrangements in the Pickering IFBs.	3. Enhanced confidence in the safety analyses	0.21	The resolution of this Global Issue is related to the seismic qualification that would impact the safety analyses of the IFBs.	5	Issue resolution can occur within 2 years, with immediate impact on the objective.	3	The resolution would have a direct and minor impact on the objective.	0.46	0.097
GI-10-RS1 Complete the Pickering 5-8 IFB Leakage Mitigation Project to mitigate leaks from IFB-B to the interspace.	2. Enhanced Confidence in the fitness for service of SSCs	0.29	The issue is directly related to FFS of the IFBs.	5	The Pickering 5-8 IFB Leakage Mitigation Project is expected to be complete within 2 years, with immediate impact on the objective.	3	Resolving the issue will have a direct and minor impact on the FFS of IFBs.	0.46	0.133
GI-12-RS1 Complete EQA re-assessments to support the extended operating period.	2. Enhanced Confidence in the fitness for service of SSCs	0.29	Environmental qualifications of the equipment and their Condition Assessments impact the FFS.	5	Issue resolution can occur within 2 years, with immediate impact on the objective.	3	Environmental Qualification of equipment has a direct and minor impact on the FFS.	0.46	0.133
GI-19-RS1 Demonstrate the FFS of the foundation steel H-piles for the Pickering A Reactor Building, Vacuum Building and Pressure Relief Duct at the Pickering site for the extended operating period.	2. Enhanced Confidence in the fitness for service of SSCs	0.29	The demonstration of FFS includes inspections, testing or analysis to confirm the integrity of foundation steel H-piles.	5	Issue resolution can occur within 2 years, with immediate impact on the objective.	3	Resolving the issue will have a direct and minor impact on the objective, given the results to date.	0.46	0.133
GI-24-RS1 Update Heat Transport System aging safety analysis models and perform the required safety analysis of events most impacted by aging (SBLOCA, LOF and Neutron Overpower (NOP)) to support extended operation.	3. Enhanced confidence in the safety analyses	0.21	Aging analysis models need to be developed and the safety analysis impacted by aging is required to be updated to demonstrate the adequacy of safety margins for extended operation.	5	Issue resolution can occur within 2 years, with immediate impact on the objective.	5	The resolution of this issue will have a direct and major impact on the objective. Completing the required safety analysis will directly support the safety case for continuing operation.	1.00	0.210
GI-25-RS1 Complete the re-categorization of the Large Break LOCA (LBLOCA) CANDU Safety Issues to Category 2.	3. Enhanced confidence in the safety analyses	0.21	The Resolution Statements will be the bases for OPG request to re-classify the CSIs on large break LOCA to category 2 to support Pickering safety case.	5	Given the industry progress in addressing the findings of CNSC staff reviews, it is expected that the re-categorization will be approved by CNSC with immediate impact on the objective.	2	Resolving the issue will have an indirect and minor impact on the objective as work has already been performed and CNSC approval is pending.	0.26	0.055

Global Issue/RS Title	Objective	Objective Weight	Objective Justification	Time Attribute	Time Attribute Justification	Impact Attribute	Impact Attribute Justification	Utility Score	GI-RS Ranking Value
GI-25-RS2 Complete the re-categorization of CANDU Safety Issue CSI-IH6 for Pickering to Category 2. (Pickering 1,4 high-energy piping)	3. Enhanced confidence in the safety analyses	0.21	The Resolution Statement will be the bases for OPG request to re-classify the CSI-IH6 to category 2 to support Pickering safety case.	5	Issue resolution is expected soon, with immediate impact on the objective.	3	Resolving the issue will have a direct and minor impact on the objective.	0.46	0.097
GI-26-RS1 Complete the emergency response projection enhancements identified in Action Item 2016-OPG-7469: Implementation of Emergency Response Projection Computer Code Upgrades.	5. Enhanced confidence in the management processes	0.11	The issue is related to the development of an improved emergency response tool to predict emergency response projections.	5	Issue resolution can occur within 2 years, with immediate impact on the objective.	5	Resolving the issue will have direct and major impact on the objective.	1.00	0.110
GI-27-RS1 Complete actions from PSA improvement Plan.	3. Enhanced confidence in the safety analyses	0.21	PSA and analysis refinements will enhance the confidence in plant overall risk.	5	Issue resolution can occur within 2 years, with immediate impact on the objective.	3	The resolution will have a direct and minor impact on the objective, given that the high impact work has been completed.	0.46	0.097
GI-27-RS2 Investigate and implement additional practicable design, operational and/or analytical enhancements to further improve Pickering 1,4 Severe Core Damage Frequency and Large Release Frequency (e.g., alternative emergency cooling water makeup).	3. Enhanced confidence in the safety analyses	0.21	Practicable design and/or operational enhancements, will reduce plant overall risk.	5	Significant progress on issue resolution can occur within 2 years with immediate impact on the objective.	5	The resolution will have a direct and major impact on the objective.	1.00	0.210
GI-31-RS1 Complete the Pickering NGS Implementation Plan for REGDOC-2.4.1.	3. Enhanced confidence in the safety analyses	0.21	This is a requirement in the Licence Conditions Handbook that is directly relevant to the confidence in the safety analysis.	4	Issue resolution may take 2-3 years with immediate impact on the objective.	3	Resolving the issue will have a direct and minor impact on the objective.	0.31	0.065
GI-31-RS2 Prepare Implementation Plan update for REGDOC-2.4.1 including consideration of the impact of the extended operating period.	3. Enhanced confidence in the safety analyses	0.21	The updated plan will identify any changes required to support the continued safe operation of Pickering NGS.	4	Issue resolution may take 2-3 years with immediate impact on the objective.	3	Resolving the issue will have direct and minor impact on the objective	0.31	0.065
GI-32-RS1 Complete the activities in the REGDOC-2.4.2 Implementation Strategy and update the Strategy in the context of the additional operating period.	3. Enhanced confidence in the safety analyses	0.21	The plan will identify scope of the REGDOC-2.4.2 implementation. This will enhance the confidence in PSA in support of the continued safe operation of	4	Issue resolution may take 2-3 years with immediate impact on the objective.	3	Resolving the issue will have a direct and minor impact on the objective.	0.31	0.065

Appendix D – Review of Safety Principles

D.1. Methodology

As described in Section 18.1, the steps in the assessment of safety principles are:

- Identification of the safety principles from [IAEA SRS-46, *Assessment of Defence in Depth for Nuclear Power Plants*, February 2005] that are applicable to the defence-in-depth review.
- Establishment of the defence-in-depth levels impacted for each applicable safety principle (taken from IAEA SRS-46).
- Mapping of each safety principle to the relevant Safety Factor(s).
- Assessment of the adequacy of the Pickering NGS design and operation with respect to each safety principle.

In the following sub-sections, each of the first three steps is described further. The results of the fourth step, the assessment of each principle, are discussed in Sections D.2 to D.12. Information on the design features of Units 1,4 and 5-8 is taken primarily from the station Safety Reports [NA44-SR-01320-00001-R016, *Pickering A Safety Report*, July 20, 2017], [NK30-SR-01320-00002-R004, *Pickering B Safety Report – Part 2*, October 10, 2012].

D.1.1. Identification of Applicable Safety Principles

[IAEA INSAG-12, *Basic Safety Principles for Nuclear Power Plants*, 75-INSAG-3 Rev. 1, October 1999] lists three safety objectives related to general nuclear safety, radiation protection and technical safety for nuclear power plants, as well as accompanying safety principles to achieve these safety objectives. Fifty-four specific safety principles are defined in the following eight categories:

- **Siting:** Four safety principles
- **Design:** Twenty-five safety principles
- **Manufacturing and Construction:** Two safety principles
- **Commissioning:** Four safety principles
- **Operation:** Twelve safety principles
- **Accident Management:** Three safety principles
- **Decommissioning:** One safety principle
- **Emergency Preparedness:** Three safety principles

The safety principle related to decommissioning was not considered in [IAEA SRS-46, *Assessment of Defence in Depth for Nuclear Power Plants*, February 2005] and is thus not included in the PSR2 Defence-in-Depth Assessment. This is considered acceptable since PSR2 is focused on operation, not decommissioning, as described in the PSR2 Basis Document [P-REP-03680-00001-R002, *Pickering NGS Periodic Safety Review 2 (PSR2) Basis Document*, June 2016].

Safety principle D-242, Physical Protection of Plant, pertains to security provisions, which are not in the PSR2 scope and therefore this safety principle is not considered here.

Therefore, 52 of the 54 safety principles in [IAEA INSAG-12, *Basic Safety Principles for Nuclear Power Plants*, 75-INSAG-3 Rev. 1, October 1999] are considered applicable to Pickering NGS and are assessed with respect to defence-in-depth for PSR2.

D.1.2. Establishment of Defence-in-Depth Levels Impacted for Each Safety Principle

Table 2 of [IAEA SRS-46, *Assessment of Defence in Depth for Nuclear Power Plants*, February 2005] assigns the safety principles in [IAEA INSAG-12, *Basic Safety Principles for Nuclear Power Plants*, 75-INSAG-3 Rev. 1, October 1999] to individual levels of defence-in-depth based on the descriptions of the safety principles. This association has been used for the PSR2 Defence-in-Depth Assessment.

In accordance with Table 2 of [IAEA SRS-46, *Assessment of Defence in Depth for Nuclear Power Plants*, February 2005], a number of safety principles are related to more than one level of defence, as follows:

- **Levels 1, 2, 3, 4, 5:** Three safety principles
- **Levels 1, 2, 3, 4:** Twenty safety principles
- **Levels 1, 2, 3:** Four safety principles
- **Levels 3, 4, 5:** One safety principle
- **Levels 1, 2:** Four safety principles
- **Levels 3, 4:** Five safety principles
- **Levels 4, 5:** Two safety principles

Some safety principles are related to only one level of defence, as follows:

- **Level 1:** Four safety principles
- **Level 3:** Five safety principles
- **Level 4:** Three safety principles
- **Level 5:** One safety principle

D.1.3. Mapping of Safety Principles to Relevant Safety Factor Reviews

Based on the description of each safety principle and the associated level or levels of defence, each safety principle is mapped to one or more of the Safety Factors. In the mapping of the safety principles to the Safety Factors, consideration is given to the review tasks of each Safety Factor, as well as the modern Laws, Regulations, Codes and Standards assessed for each Safety Factor.

D.1.4. List of Safety Principles

Table 32, based on Table 2 of [IAEA SRS-46, *Assessment of Defence in Depth for Nuclear Power Plants*, February 2005], lists the safety principles together with applicable levels of defence-in-depth (see Section 18 for a brief description of defence-in-depth levels), as well as the Safety Factors related to them. The table is arranged such that safety principles applicable to the greatest number of defence-in-depth levels are listed at the top. Ascending order of defence-in-depth levels is used as the secondary ordering sequence[34].

In Table 32, each safety principle is assigned a number in accordance with the number provided in Table 2 of [IAEA SRS-46, *Assessment of Defence in Depth for Nuclear Power Plants*, February 2005], preceded by one of the following:

- S – Siting
- D – Design
- M&C – Manufacture and Construction
- C – Commissioning
- O – Operation
- AM – Accident Management
- EP – Emergency Preparedness

Table 32: Relation of Safety Principles to Defence-in-Depth Levels and Safety Factors

No.	Safety Principle (extracted from Table 2 of SRS-46)	Levels	Safety Factor
S-138	Radiological Impact on the Public and the Local Environment	1, 2, 3, 4, 5	1, 6, 14
O-265	Organization, Responsibilities and Staffing	1, 2, 3, 4, 5	2, 10, 12, 13

[34] Ascending order used as the secondary ordering sequence means that the groups of safety principles that are applicable to, e.g., three defence-in-depth levels (lmn) are ordered by ascending numerical value of “lmn”. For example, the hypothetical group applicable to defence-in-depth levels 134 comes before the group applicable to defence-in-depth levels 235, since halting an event at a lower level is preferable.

No.	Safety Principle (extracted from Table 2 of SRS-46)	Levels	Safety Factor
O-296	Engineering and Technical Support of Operations	1, 2, 3, 4, 5	2, 10, 12
S-142	Ultimate Heat Sink Provisions	1, 2, 3, 4	1
D-150	Design Management	1, 2, 3, 4	1, 5, 8, 10, 12

S-140	Feasibility of Emergency Plans	5	1, 13

D.2. Safety Principles Related to Levels 1, 2, 3, 4, 5

The following safety principles are related to all five levels of defence-in-depth:

- S-138 – Radiological Impact on the Public and the Local Environment
- O-265 – Organization, Responsibilities and Staffing
- O-296 – Engineering and Technical Support of Operations

As demonstrated below, Pickering NGS design and operation are aligned with all safety principles related to all Levels 1, 2, 3, 4, 5.

S-138 – Radiological Impact on the Public and the Local Environment

Principle: Sites are investigated from the standpoint of the radiological impact of the plant in normal operation and in accident conditions.

The radiological impact on the public and the local environment was considered at the Pickering NGS design stage, when the site characteristics were established, as described in regards to Safety Principle S-136, External Factors Affecting the Plant. The site characteristics are documented in Part 1 of the Pickering NGS Safety Reports. The minimal impact of the operation of Pickering NGS is confirmed through the Pickering environmental monitoring program [N-REP-03443-10014-R000, *2014 Results Of Environmental Monitoring Programs*, April 20, 2015]. The environmental monitoring program has been established to ensure that activities at Pickering are conducted in a manner that minimizes the impact on the public and the environment. The objectives of the environmental monitoring program are:

1. To assess the impact on the public and the environment associated with the operation of OPG Nuclear facilities.
2. To demonstrate compliance with limits associated with releases from Pickering.
3. To demonstrate the effectiveness of the control programs.
4. To verify predictions made by Environmental Risk Assessment [P-REP-07010-10012-R000, *Environmental Risk Assessment Report For Pickering Nuclear*, January 27, 2014].

The Environmental Monitoring Program Sampling Plan [N-REP-03443-10014-R000, *2014 Results Of Environmental Monitoring Programs*, April 20, 2015] outlines the radionuclides monitored, the sampling locations, the sample types and the frequency of collection. To calculate the public dose from radiological emissions, various exposure pathways, such as food ingestion, inhalation and water ingestion, are considered. Samples are collected at station boundary locations, as well as at other specified locations.

The data are collected annually, or more frequently, e.g., milk from local dairy farms is sampled on a monthly basis, and comprehensive assessment and reporting is performed annually.

Site specific surveys allow identification of the various potential critical groups around each nuclear site. The site specific surveys are used for development of the environmental monitoring programs and site derived release limits, and for calculating public collective dose. Site-specific survey instructions are documented in OPG Instruction [N-INS-03481-10000-R000, *Instruction For Performing A Site Specific Survey For Ontario Power Generation Nuclear Sites*, September 23, 2009]. Specific responsibilities of environment operations support related to site-specific surveys are outlined in OPG Procedure [N-PROC-OP-0025-R011, *Management Of The Environmental Monitoring Programs*, January 8, 2016].

The Environmental Risk Assessment [P-REP-07010-10012-R000, *Environmental Risk Assessment Report For Pickering Nuclear*, January 27, 2014] was performed in 2014. As part of this assessment, an assessment of the radiological dose received by terrestrial and aquatic biota from air, surface water and soil was performed.

Section 1.2.4 of OPG Program [N-PROG-OP-0006-R018, *Environmental Management*, April 29, 2015] states that radiological emissions from OPG Nuclear facilities shall not exceed the derived release limits specified in station Power Reactor Operating Licences issued by the CNSC. Section 1.2.4 of OPG Program [N-PROG-OP-0006-R018, *Environmental Management*, April 29, 2015] makes reference to OPG Standard [N-STD-OP-0031-R006, *Monitoring Of Nuclear And Hazardous Substances In Effluents*, October 1, 2014], which establishes minimum requirements for the monitoring of airborne and waterborne effluents from OPG Nuclear facilities operating under normal and abnormal operating conditions.

In the OPG Standard [N-STD-OP-0031-R006, *Monitoring Of Nuclear And Hazardous Substances In Effluents*, October 1, 2014] OPG facilities are required to have an Emission Monitoring Plan that documents the site's emission monitoring program. OPG Plan [P-PLAN-03480-00001-R000, *Pickering Nuclear Radioactive And Hazardous Emissions Monitoring Plan*, January 31, 2017] outlines the Pickering-specific monitoring requirements for the radiological airborne and liquid effluent pathways. This plan also outlines compliance of the monitoring program with CSA N288.5-11, *Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills*, and therefore demonstrates that a comprehensive program for monitoring effluent releases is in place.

The radiological impact of postulated accidents on the public is assessed in Part 3 of the Pickering NGS Safety Reports [NK30-SR-01320-00003-R004, *Pickering Nuclear 5-8 Safety Report: Part 3 Accident Analysis Vol 1-5*, October 10, 2014], [NA44-SR-01320-00002-R004, *Pickering Nuclear 1-4 Safety Report: Part 3 – Accident Analysis*, October 31, 2013]. Conservative estimates of whole body and thyroid doses to the critical individual at the site boundary and to the population are calculated using the site-specific terrain, meteorological conditions and population data and are compared against the regulatory dose limits.

The impact of BDBAs, including severe accidents, is also assessed in the PSA against the Large Release Frequency Safety Goal. This ensures that the risk of a large radiological impact is understood and is acceptable, and that emergency planning is effective. The results of the PSAs show that the Safety Goals are met for Pickering NGS [P-REP-03611-00006-R000, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan,* April 30, 2014].

To summarize, the Pickering environmental monitoring program provides comprehensive monitoring of normal and inadvertent radioactivity releases from Pickering NGS, such that the radiological impact is understood. The radiological impact from postulated accidents within the design basis is assessed and the risk associated with BDBAs is understood and meets established Safety Goals. Therefore, all levels of defence-in-depth are effectively addressed with regard to radiological impact on the public and the local environment.

O-265 – Organization, Responsibilities and Staffing

Principle: The operating organization exerts full responsibility for the safe operation of a nuclear power plant through a strong organizational structure under the line authority of the plant manager. The plant manager ensures that all elements for safe plant operation are in place, including an adequate number of qualified and experienced personnel.

OPG has a well-defined organizational structure and strong lines of authority. Although all functions in the organizational structure support operating units, some portions, such as the Environment unit, are centre-led under OPG as a whole, rather than specifically under OPG Nuclear. OPG Standard [N-STD-AS-0020-R014, *Nuclear Management Systems Organizations*, May 19, 2016] establishes the lines of authority and definition of duties. It provides a summary of the interfacing organizations that own programs supporting the Nuclear Management System. Operation and maintenance of the station as per regulatory requirements and Nuclear standards for public safety are directed by the Director, Operations and Maintenance, who also coordinates with the centre-led organizations to effectively use resources to achieve performance targets. The quality and quantity of services provided by these centre-led support organizations are monitored by the Senior Site Vice President, who holds responsibility for establishing site requirements and priorities. Position-specific role documents in the N-MAN-08131 series describe the duties, authorities and accountabilities of the positions described in the standard. Additional guidance is given in OPG Programs [N-PROG-OP-0001-R008, *Nuclear Operations*, December 4, 2015], [N-PROG-MA-0004-R011, *Conduct Of Maintenance*, May 5, 2015] and [N-PROG-MP-0007-R012, *Conduct Of Engineering*, October 26, 2012]. The training and qualification description document [N-TQD-601-00001-R017, *Leadership And Management Training And Qualification Description*, May 4, 2015] provides qualification and professional development requirements for supervisors and managers, including Safety Culture for Managers.

OPG Charter [N-CHAR-AS-0002-R019, *Nuclear Management System*, November 1, 2016] gives authority to the OPG Nuclear safety processes and defines responsibilities. It specifies that the Chief Nuclear Officer is accountable for:

> “the effectiveness of the overall Nuclear Management System in ensuring our Nuclear facilities are operated and maintained using sound Nuclear safety and defence-in-depth practices to ensure radiological risks to workers, the public, and environment are as low as reasonably achievable, and in keeping with the Nuclear Safety Policy, and the best practices of the international Nuclear community.”

Managers ensure that tasks are executed as defined through OPG Program [N-PROG-AS-0002-R016, *Human Performance*, May 5, 17, 2016]. This program is specifically designed to achieve higher levels of nuclear and industrial safety, higher unit reliability and reduced operating costs through event-free operation. This performance is accomplished through pre-job briefings, post-job debriefings, self-checking programs, communications, self-assessments, and an observation and coaching program.

OPG Program [N-PROG-TR-0005-R016, *Training*, January 5, 2016] describes the training program for regular staff, contractors, temporary personnel and other staff assigned work. It includes the structure, processes and tools for defining, developing, implementing, documenting, assessing and improving the training required to ensure that nuclear staff have the appropriate knowledge, skill and attitudes for safe and efficient plant operation.

As described in Section 1.6.3 of [P-CORR-00531-03719-R000, *Application For Renewal Of Pickering Nuclear Generating Station Power Reactor Operating Licence*, July 4, 2012], OPG identifies qualified and competent individuals for key positions. With career development and succession planning being key elements in the management capability strategy, a Corporate Succession Plan ensures that individuals with high leadership potential are identified.

To conclude, the existing corporate structure supports well-defined lines of responsibility throughout the organization. In particular, the appropriate functions are in place and adequately staffed to support and enhance nuclear safety at all levels of defence-in-depth.

O-296 – Engineering and Technical Support of Operations

Principle: Engineering and technical support, competent in all disciplines important for safety, is available throughout the lifetime of the plant.

The roles and responsibilities of individuals responsible for safe operation are clearly defined and documented in published OPG Nuclear organization procedures [N-STD-AS-0020, *Nuclear Management Systems Organization,* February 2015]. This organization is understood and effective governance is in place to ensure availability of these resources and control organizational changes.

At OPG, positions are filled based on knowledge and skill requirements as identified in Training and Qualification Documents and in Qualification Guides. For example, Table 1 of OPG Instruction, N-INS-03490-10003 [*Minimum Shift Complement Resources, Qualifications and Procedures Required For Responding to Resource Limiting Events*, November 2013] lists the Training and Qualification Documents (TQDs) associated with Minimum Shift Complement staff qualification requirements. Individuals are either recruited with the necessary knowledge and skills documented in the Training and Qualification Documents and Qualification Guides, or are provided training prior to working independently. The Training and Qualification Documents and the Qualification Guides cover technical and engineering support functions, including but not limited to fire protection, radiation protection and maintenance. OPG also has consultants and contractors to support the operating organizations. The review of Safety Principle M&C-249, Achievement of Quality, describes OPG processes for ensuring quality in procured services.

The new hire engineering support training is intended to support the continued availability of trained and competent staff for technical positions within Engineering. The education background requirement for the new hire engineering support as engineering graduates or equivalent is provided in [N-TQD-403-00001, *Nuclear Engineering Support Personnel Training And Qualification Description*, September 21, 2016]. Once recruited, the new hires are required to go through a structured training program per OPG Procedure [N-PROC-TR-0008, *Systematic Approach To Training*, December 5, 2016]. The content is based on what a new graduate engineer initially needs to know to work at a nuclear power plant. In addition, there is training for the engineer once he/she situates in a home department. The new hire engineers are then put through training that includes initial training for core, extended core and duty area qualifications. This training is completed within three years from entering an engineering position.

In conclusion, adequate programs are in place and implemented to ensure that the appropriate engineering and technical capability is available to support nuclear safety at all levels of defence-in-depth.

D.3. Safety Principles Related to Levels 1, 2, 3, 4

The following safety principles are related to defence-in-depth Levels 1, 2, 3, 4:

- S-142 – Ultimate Heat Sink Provisions

- D-150 – Design Management
- D-154 – Proven Technology
- D-158 – General Basis for Design
- D-186 – Inspectability of Safety Equipment
- D-205 – Startup, Shutdown, and Low Power Operation
- D-227 – Monitoring of Plant Safety Status
- D-230 – Preservation of Control Capability
- M&C-246 – Safety Evaluation of Design
- M&C-249 – Achievement of Quality
- C-255 – Verification of Design and Construction
- C-258 – Validation of Operating and Functional Test Procedures
- C-260 – Collection of Baseline Data
- C-262 – Pre-Operational Adjustment of Plant
- O-269 – Safety Review Procedures
- O-290 – Emergency Operating Procedures
- O-292 – Radiation Protection Procedures
- O-299 – Feedback of Operating Experience
- O-305 – Maintenance, Testing and Inspection
- O-312 – Quality Assurance in Operation

As demonstrated below, Pickering NGS design and operation are aligned with all safety principles related to Levels 1, 2, 3, 4.

S-142 – Ultimate Heat Sink Provisions

Principle: The site selected for a nuclear power plant has a reliable long term heat sink that can remove energy generated in the plant after shutdown, both immediately after shutdown and over the longer term.

The ultimate heat sink for energy generated in the plant during normal operation and after shutdown is Lake Ontario. All water for equipment cooling and/or services in Pickering NGS Units 1,4 and 5-8 is drawn from Lake Ontario through an intake channel bounded by two groynes extending into the lake. Lake water is drawn through the station intake to the common screenhouse on the forebay. The water is strained through bar racks and traveling screens in the screenhouse and then flows through a common duct to a common pump suction header under the powerhouse. This water is used for cooling by the Condenser Circulating Water System and station Service Water Systems, and is returned to the lake through the cooling water discharge duct or through the Reactor Building discharge duct.

The Pickering NGS units are provided with the following Cooling/Service Water Systems:

- Condenser Circulating Water System
- Low Pressure Service Water System
- High Pressure Service Water System
- Recirculated Cooling Water System
- Vacuum Building Emergency Storage Water System

When the reactor is shut down for maintenance or to repair equipment, the Shutdown Cooling System removes residual heat. High Pressure Service Water is supplied to the shell side of the shutdown cooling heat exchangers. The High Pressure Service Water System has been upgraded as part of the return of Units 1,4 to service. The upgrades include installation of larger capacity Class III pumps and separation of the Class III High-Pressure Service Water System supply from the Class III Low Pressure Service Water System. Two 100 percent deep well pumps operating on Class III power supply high pressure service water in the event of a loss of Class IV power.

In Units 5-8, two of the high pressure service water pumps are powered by Class IV power, and two pumps are powered by Class III power. High pressure service water is supplied to the shutdown coolers only by Class IV power, and therefore, if Class IV power fails while a shutdown cooling circuit is operating, the Steam Generators become the primary heat sink. Steam is rejected to the atmosphere through the steam reject valves.

The Emergency Boiler Water Supply System is designed to provide emergency water to the boilers of Units 1,4. The emergency water is supplied from the discharge headers of the Units 6 and 7 High Pressure Service Water System. The system is credited as an emergency heat sink for Units 1,4.

In Units 5-8, the Emergency Water System supplies emergency makeup to the boilers for decay heat removal following an irrecoverable failure of the feedwater supply. The Emergency Water System is seismically qualified and is powered from the Emergency Power System.

The Emergency Water Storage Tank in the top of the Vacuum Building serves as a passive emergency supply of water to Pickering Units 5-8 in the event of failure of both Group I and Group II heat sinks. Under certain circumstances, such as loss of shutdown cooling capability, the steam generators become the primary heat sinks by rejecting steam to atmosphere through the steam reject valves.

Emergency heat removal capability, including the provision of Emergency Mitigating Equipment for accidents beyond the design basis, is described and reviewed in Safety Principle D-207, Emergency Heat Removal.

To summarize, multiple systems of adequate capacity, and their support systems, are in place to ensure that an appropriate heat sink for the Fuel exists in operating and shutdown/outage conditions, as well as in response to DBAs and BDBAs.

D-150 – Design Management

Principle: The assignment and subdivision of responsibility for safety are kept well defined throughout the design phase of a nuclear power plant project, and during any subsequent modifications.

OPG Program [N-PROG-MP-0009-R012, *Design Management*, May 12, 2017] provides the framework for the establishment, maintenance and compliance with the design basis for Pickering NGS. The design management program provides assurance that design and procedure changes are prepared, reviewed, approved, documented and implemented in accordance with approved procedures, applicable regulatory requirements, standards and industry practices.

N-PROG-MP-0009-R012 requires that design changes be initiated, implemented and tracked in accordance with OPG Program [N-PROG-MP-0001-R015, *Engineering Change Control*, May 12, 2017]. The engineering change control program defines a systematic process and methodology for controlling design modifications for plant SSCs. A primary input to the modification process is defined in OPG Procedure [N-PROC-MP-0083-R009, *Constructability, Operability, Maintainability, And Safety (COMS)*, April 21, 2016] and OPG Form [N-FORM-10480, *COMS Checklist*, April 22, 2016]. N-PROC-MP-0083-R009 provides direction on:

1. The identification of stakeholders from departments involved with or impacted by the modification.
2. Determination of which stakeholders comprise the Constructability, Operability, Maintainability and Safety team.

N-FORM-10480 is a repository of questions to assist in determining whether all appropriate issues have been identified during the design phase. The use of N-PROC-MP-0083-R009 and N-FORM-10480 ensures that stakeholder and subject matter expert input is considered and that risks impacting the safety of the plant and personnel are adequately identified and addressed.

In summary, the Pickering NGS design management program defines the appropriate processes to ensure that nuclear safety requirements are met in the planning and execution of design modifications.

D-154 – Proven Technology

Principle: Technologies incorporated into design have been proven by experience and testing. Significant new design features or new reactor types are introduced only after thorough research and prototype testing at the component, system or plant level, as appropriate.

Pickering was the first large-scale CANDU power reactor design and was the culmination of a series of CANDU demonstration plants at increasing scale (specifically, Nuclear Power Demonstration and Douglas Point). In addition, the CANDU design has benefitted from decades of experience and knowledge acquired through the design and operation of heavy water research reactors at Chalk River. Experience gained at each stage of the design development process was used to guide and improve the design at the next stage. The excellence and inherent safety features of the CANDU design have been proven through more than 500 reactor-years of safe and reliable operation worldwide since Pickering NGS Units 1-4 were first put into service.

The process for adopting and implementing design changes, including those which can be characterized as significant new design features is governed by OPG Program [N-PROG-MP-0009-R012, *Design Management*, May 12, 2017]. This program requires that design changes are initiated, implemented and tracked in accordance with OPG Program [N-PROG-MP-0001-R015, *Engineering Change Control*, May 12, 2017]. The engineering change control program defines a systematic process and methodology for controlling design modifications for plant SSCs to meet the requirements of CSA N285.0, *General Requirements for Pressure-Retaining Systems and Components in CANDU Nuclear Power Plants* and CSA N286, *Management System Requirements for Nuclear Power Plants*.

OPG actively participates in the research and development activities in CANDU and related technologies to improve plant operation, equipment performance and reliability and analytical capabilities and scientific codes used in engineering and safety analysis.

To conclude, the use of proven technology has always been a driving principle at Pickering NGS, and appropriate processes are in place to address the provenness of design modifications.

D-158 – General Basis for Design

Principle: A nuclear power plant is designed to cope with a set of events including normal conditions, anticipated operational occurrences, extreme external events and accident conditions. For this purpose, conservative rules and criteria incorporating safety margins are used to establish design requirements. Comprehensive analyses are carried out to evaluate the safety performance or capability of the various components and systems in the plant.

The Pickering NGS design was developed using the principles of defence-in-depth. Inherent to this approach is the requirement to postulate a range of process equipment failures which would impair one or more of the barriers and establish that resultant releases of radioactive material will not result in radiation doses above allowable limits. To meet this requirement, a number of safety-related functions (as distinct from process functions associated with routine power production) are provided. The levels of events considered and the alignment of the Pickering NGS design against them can be summarized as:

1. **Level 1 – Prevent deviations from normal operation and prevent failures of SSCs**

   The first level of defence requires a high quality in the design and construction of the plant with barriers to prevent the occurrence of abnormal operating conditions. This is particularly important for the physical barriers surrounding the radioactive material in the Fuel. Safe, conservative operation of the plant by qualified staff and a continued focus on preventive maintenance ensures reliable functionality of plant equipment under normal operation and therefore prevents process upsets and failures.

2. **Level 2 – Detect and intercept deviations from normal operation in order to prevent process upsets from escalating to accident conditions**

   The second level of defence is the provision of barriers to prevent process upsets from progressing to accidents. The Pickering NGS plant design possesses a number of strong features regarding defence-in-depth Level 2. For example:

   - Automatic reactor control features detect and respond to abnormal conditions before these conditions progress to the point that the next level of barriers are required to act.
   - A large number of Safety-Related System tests are completed routinely, based on prescribed schedules to detect problems regarding plant equipment.
   - A well-established framework of operating procedures is in place to respond to equipment malfunctions in a timely manner thereby ensuring that the plant stays within its well-defined SOE.

3. **Level 3 – Minimize the consequences of accidents**

   The third level of defence consists of the barriers to minimize the consequences of accidents should they occur by providing inherent safety features, fail-safe design, additional equipment (including Emergency Mitigating Equipment) and mitigating procedures. The Pickering NGS Units 1,4 and 5-8 Safety Reports demonstrate that the radiological consequences of postulated accidents within the design basis meet established dose limits. The PSA [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014] demonstrates that the overall plant design has a Core Damage Frequency and Large Release Frequency within the specified Safety Goals, indicating robustness in the design and reliable equipment that is capable of responding effectively to accident scenarios.

4. **Level 4 – Ensure that radioactive releases caused by severe accidents are kept as low as practicable**

   The fourth level of defence includes those barriers to control severe plant conditions. Significant improvement in the Severe Accident Management Guidelines implementation has resulted in Pickering NGS strengthening its capability to respond to low probability severe accidents. Implementation of lessons learned from the 2011 Fukushima accident, and enhancements to power supplies for hydrogen mitigation equipment for BDBAs, will add further capability to this defence-in-depth level (see GI-40-RS1 in Appendix F).

The scope of postulated initiating events addressed by the existing deterministic safety analysis for Pickering NGS Units 1,4 and 5-8 (Part 3 of the Safety Reports), consists of single/dual failure events based on the requirements of the Siting Guide. As outlined in [N-CORR-00531-18239, *Progress Report on OPG Safety Analysis Improvement and REGDOC-2.4.1 Implementation*, October 17, 2016], OPG has developed an implementation plan, which defines the CNSC REGDOC-2.4.1 compliant analyses to be undertaken in the 2014-2017 timeframe.

For protection against seismic events, Units 1,4 were constructed according to the National Building Code of Canada seismic provisions, whereas Units 5-8 included specific provisions to withstand a prescribed Design Basis Earthquake. The Units 1,4 SSCs required to perform functions during and following an earthquake were not originally required to be seismically qualified. However, the common Containment structures (Reactor Building, Pressure Relief Duct and Vacuum Building) were designed to exceed the National Building Code 1965 seismic design provisions and were subsequently confirmed analytically to meet Units 5-8 Design Basis Earthquake seismic design requirements. The OPG Report [NA44-REP-02004-0073-R000 Vol 1-7, *Seismic Assessment of Pickering A Nuclear Generating Station Summary Repor*t, February 25, 1998] evaluated the seismic capacity of those Pickering A SSCs required to perform the above functions and identified necessary seismic upgrades, which have been implemented. Seismic success path SSCs were identified and updated in OPG Report [NA44-REP-02004-00002-R001, *Pickering NGS A Seismic Success Path Addendum Including the Safe Shutdown Equipment List*, August 13, 2013]. The Electric Power Research Institute/Seismic Qualification Utility Group seismic margin assessment methodology was used to evaluate seismic capacity of the seismic success path, as well as to verify the seismic adequacy of supporting structures and services.

Subsequently, a screened list of internal and external events for inclusion in the Level 1/Level 2 PSA for the Pickering NGS Units 1,4 and 5-8 was completed as part of the hazard screening analysis completed in 2012 and includes discussion of pipe whip, missiles, explosions, toxic gas (external), flooding (external), extreme temperatures, and aircraft impacts [P-REP-03611-00006-R000, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan,* April 30, 2014].

To summarize, Pickering NGS includes SSCs designed to cope with a set of events, including normal conditions, external events and accident conditions with appropriate safety margins, based on assessments of the events that challenge the barriers to radioactivity release.

D-186 – Inspectability of Safety Equipment

Principle: Safety related components, systems and structures are designed and constructed so that they can be inspected throughout their operating lifetimes to verify their continued acceptability for service with an adequate safety margin.

Periodic inspection is the mandatory non-destructive examination of nuclear equipment. It provides assurance that the likelihood of failure remains acceptably low throughout the operating lifetime. The Periodic Inspection Program (PIP) at Pickering NGS is prepared on the basis of a sampling system which selects components subject to the most severe operating conditions from the nuclear process systems. The program delineates the selection of inspection areas, inspection frequency, procedures, techniques and acceptance criteria, the collection and recording of data and the reporting of results. The complete program and any revisions thereto must be approved by the regulatory authority. To meet these requirements the design and arrangement of components provides for access for inspection and maintenance.

Regarding periodic inspections, the Licence Conditions Handbook states that "OPG shall carry out periodic inspections in accordance with the accepted PIP documents. If a deviation from the accepted PIP program is anticipated during inspection planning activities, OPG shall obtain CNSC acceptance prior to conducting the affected inspections. However, for any findings, discoveries or deviations from the accepted PIP that are identified during an inspection, OPG shall provide justification to CNSC in the inspection report submission following OPG governance, OPEX and best industry practices. For permanently required exemptions to the requirements of CSA PIP standards, OPG shall revise the affected PIP document accordingly prior to issuing the next scheduled revision of the PIP document." The Licence Conditions Handbook wording provides a way to resolve a deviation from the accepted PIP. If a permanent concession is needed as a result of future updates to CSA Standards associated with PIPs, this concession will need to be updated. CNSC acceptance will be obtained at that time if it is needed.

Inspection of key SSCs is facilitated in the design as follows:

- Pressure boundary piping is monitored using non-destructive inspection techniques to assure that the likelihood of a pipe failure is kept low. The scope of periodic inspection includes components, piping and supports. Radiation fields are held to levels that permit personnel access for maintenance and inspection of the Heat Transport System, Shutdown Cooling, ECI and Heat Transport Relief System components.
- Pressure tube leaks can be readily detected by monitoring the moisture content and pressure in the gas space between the pressure tube and Calandria tube. This is done on a continuous basis. In addition, ultrasonic scanning devices can be mounted on the fuelling machines for periodic in-service inspection of the pressure tubes. Fuel Channel inspections and Fuel Channel fitness for service are governed by CSA N285.4, *Periodic Inspection of CANDU Nuclear Power Plant Components*, and compliance to this standard is required by the Power Reactor Operating Licence. As per the Pickering Fuel Channels Fitness for Service submission [P-CORR-00531-04953, *Pickering NGS-Assurance of Fuel Channel Fitness-for-Service for the Assumed Target Service Life of*

the Pickering Units, April 4, 2017], the Life Cycle Management Plan for Fuel Channels [N-PLAN-01060-10002-R017, *Fuel Channel Life Cycle Management Plan*, October 2016] includes inspection scope that exceeds the minimum requirements of CSA N285.4 to demonstrate fitness for service.

- The Feeder Life Cycle Management Plan [N-PLAN-01060-10001-R018, *Feeders Life Cycle Management Plan*, October 2016] specifies the required PIP, in-service inspections and maintenance for Feeders. The Feeders Life Cycle Management Plan is revised on a regular basis to capture changes that may be required in response to issues identified by inspection, industry experience and ongoing research activities. As per the Fitness for Service Memorandum [P-CORR-01060-0632223, *Fitness for Service of Major Components,* February 2017], the latest inspection results demonstrate that the most recent measured wall thickness remained greater than the minimum allowable wall thickness and will be fit for service for the next operating cycle. Each Pickering unit conducts inspections periodically. The thickness inspections for future scopes are focused on monitoring lead Feeders and dispositioned Feeders. Lead Feeders are those that are approaching their minimum design-required thickness. Dispositioned Feeders are those with specific analysis defining their service limits which were accepted by the CNSC. This population has been determined by previous campaigns where 100% of the Feeder inspections were completed. The inspection scope increases as the dispositioned Feeder population increases. As per the Life Cycle Management Plan, these Feeders will continue to be monitored.
- According to the Fitness for Service Memorandum [P-CORR-01060-0632223, *Fitness for Service of Major Components,* February 2017], each Pickering NGS unit has a Steam Generator inspection approximately every two years during planned unit outages. The Steam Generator Life Cycle Management Plan identifies the inspection scope to identify active and plausible tube degradation mechanisms and the extent of the condition in the Steam Generators.

In addition to the Major Components inspection program, OPG conducts regular inspection, testing and maintenance throughout the plant, as per OPG program [N-PROG-MA-0004-R011, *Conduct of Maintenance*, May 2015].

As part of the engineering change control process [N-PROG-MP-0001-R015, *Engineering Change Control*, May 12, 2017], all station modifications are evaluated to ensure maintainability requirements are considered in the design.

In conclusion, OPG has a robust and multi-faceted SSC inspection program, such that the current condition of the plant is well understood. This provides a solid baseline for the intended operation extension as well as confidence that the requisite data will continue to be acquired going forward.

D-205 – Startup, Shutdown, and Low Power Operation

Principle: Components, structures, and systems used during startup, low power and shutdown operations are designed to maintain or restore the reactivity control, decay heat removal, and the integrity of the fission product barriers, so as to prevent the release of radioactive material resulting from accidents initiated during those operations.

Normally, the Reactor Regulating System is used to control reactor power including during reactor startup and shutdown. Reactor shutdown by the Reactor Regulating System can be initiated manually through a keyboard or by a special setback pushbutton on the control panel. The Reactor Regulating System uses light water liquid zone controllers, adjuster rods, control absorbers (Pickering Units 5-8), and moderator boron/gadolinium addition for reactivity control.

In addition to the Reactor Regulating System, the Shutdown Systems can also be used to shut down the reactors with either shutoff rods or the Liquid Injection Shutdown System (Pickering 5-8), or a moderator discharge (dump) capability (Pickering 1,4).

For a Guaranteed Shutdown State (during outages), several means are available for keeping the reactors shut down:

- **Overpoisoning:** One method used for keeping the reactor in a guaranteed shutdown state is by adding neutron absorbing chemicals (poison) to the Moderator.
- **Moderator Drain:** Draining the Moderator into separate storage tanks is another way of putting the reactor in a guaranteed shutdown state.
- **Rod Based:** In the Rod Based guaranteed shutdown state, the shutoff rods and control absorbers are placed in the in-core position, and controls are in place to prevent inadvertent removal. Poison is added to the Moderator and adjuster rods are placed in core for extra subcriticality margin as a conservative measure.

The instrumentation for initial startup comprises two complementary Neutron Detecting Systems, one using neutron proportional counters, the other out-of-core counters. Only the out-of-core counters are required for low-level startup after an extended shutdown period. Neutron poison (boron) solution can be added to the Moderator to suppress excess reactivity and can be removed by ion exchange. It is used to suppress relatively long-term excess reactivity due to fresh Fuel and is used for reactivity control during unit startups.

In Units 1,4, on SDSA each trip channel can be connected to a channel of start-up instrumentation which measures very low levels of neutron flux. Start-up instrumentation is credited as a replacement for the neutron overpower protection and Log N rate trip parameters at very low reactor power levels. Each start-up instrumentation channel consists of a neutron detector, amplifiers and ratemeter that activates an alarm module on high neutron count rate and low neutron count rate. The instrumentation satisfies the requirement for measurement of neutron flux level when in the guaranteed shutdown state and on the approach to critical.

In Units 5-8, the initial start-up instrumentation comprised two complementary Neutron-Detecting Systems. One system had neutron proportional counters located in a horizontal in-core flux detector tube, while the other system used counters located out-of-core in a spare compartment in the SDS2 ion chamber housings. Only the out-of-core counters are required for any subsequent low-level start-up after an extended shutdown period. Protection against reactivity transients is provided by the neutronic trip parameters for SDS1 and SDS2, as described in Safety Principle D-200, Automatic Shutdown Systems, and D-192, Protection Against Power Transient Accidents.

Analysis demonstrating the effectiveness of the Shutdown and Heat Removal Systems in mitigating accidents initiated during operation at all power levels, including low power levels associated with reactor startup and shutdown, is documented in Part 3 of the Pickering NGS Safety Reports. The analyzed accidents include a range of assumed control failures, electrical failures, SBLOCA (including in-core breaks) and large break LOCA, as well as failures in the Feedwater and Steam Supply System and Moderator System. The trip coverage analyses performed for these events demonstrate that there is at least one trip parameter in each of SDSA and SDSE for Pickering 1,4 (SDS1 and SDS2 for Pickering 5-8) that will shut down the reactor before Fuel sheath failure can occur.

The main condensate and feedwater pumping train has three 50 per cent system capacity condensate extraction pumps and three 50 per cent capacity feed pumps. Reactor startup and cooldown requirements are provided by an auxiliary condensate pump sized to supply 5 per cent of full load condensate flow and an auxiliary feed pump sized to supply 3 per cent of full load feedwater flow. When the reactor is shut down for maintenance or to repair equipment, Shutdown Cooling Systems remove residual heat (or decay heat).

For low power operation and reactor shutdown, the Shutdown Cooling System is provided to cool down the Heat Transport System from 177°C and maintain cooling for an indefinite period of time. The Shutdown Cooling System provides cooling for the Heat Transport System during outage operation and is designed to provide core cooling with the Heat Transport System depressurized to permit maintenance. Under emergency conditions, the shutdown coolers may be used to cool down the Heat Transport System from the operating temperature.

To summarize, Pickering NGS has the SSCs in place to control the reactor power and provide fuel cooling in response to events occurring during startup, shutdown and low power operation.

D-227 – Monitoring of Plant Safety Status

Principle: Parameters to be monitored in the control room are selected, and their displays are arranged, to ensure that operators have clear and unambiguous indications of the status of plant conditions important for safety, especially for the purpose of identifying and diagnosing the automatic actuation and operation of a safety system or the degradation of defence in depth.

The Main Control Rooms for Pickering NGS Units 1,4 and Units 5-8 contain the main control panels for each of the generating units. Each unit has its own control panels, and the panels for all units have the same layout. Two additional panels are provided for common equipment and electrical controls. All indications and controls essential for operation are located on the Main

Control Room panels. To provide post-accident monitoring capability, the critical safety parameters for Units 1,4 include:

- Reactor power level
- Reactor inlet header pressure
- Inlet Feeder temperature
- Outlet Feeder temperature
- Reactor Building water level
- Reactor Building/reactor auxiliary bay pressure differential
- Boiler level
- Boiler pressure

For Units 5-8 there is similar monitoring of critical post-accident parameters.

Colour monitors display plant data and alarms which would otherwise have to be displayed on panel indicators. Sufficient conventional display, annunciation and recording of plant variables is included to allow the plant to be maintained safely in the shutdown condition with all computers out of service. The Main Control Room is spacious to provide clear access routes and free movement within operating areas.

Information about the state of the unit is presented to the operator by a number of computer systems. This information includes sequence of events functions, display of process variables and initiation of most alarms. In both Units 1,4 and Units 5-8, the display of process variables provided by the computers complements the existing conventional instrumentation. For the digital control computers, dual channel computers provide redundancy and backup in case of failure. If both computers fail, the operator will lose some of the normal sources of information. However, information important to the safety of the unit, such as the status of all the safety systems and information about the status of the unit, is available even when computers are not available so operators will be able to establish the existence, nature and extent of any safety-related failure and take the appropriate action.

In Units 1,4, additional safety-related process information associated with critical safety parameter monitoring, SDSE and Negative Pressure Containment is provided via the Data Extraction System computer.

The following information is displayed directly on the Main Control Room panels:

- Alarm windows to indicate the tripped state of any parameter in any channel of either Shutdown System, the status of the ECI System and Containment.
- The value of each trip parameter in each channel of either Shutdown System and values of ECI System and Containment parameters.
- Other alarm windows to indicate abnormalities in the Special Safety Systems, e.g., low level in emergency storage tank.
- Alarm windows to indicate the existence of single and dual control computer failures.

- Process indicators to display information on the status of subsystems required for the operation of Special Safety Systems and Safety-Related Systems, e.g., dousing tank and Vacuum Building floor water levels and Reactor Building pressures.

Capability to monitor post-accident conditions remotely from the Main Control Room is provided in the SDSE Instrument Rooms for Units 1,4 and in the Unit Emergency Control Centres for Units 5-8. The Units 1,4 SDSE Instrument Rooms provide monitoring of the critical safety parameters listed above. The instrument rooms house SDSE trip parameters signal processing instrumentation, trip logic and monitoring computers. Buffered/isolated signals are transmitted from the instrument room to the Main Control Room to provide indications of the SDSE parameters. These instrument rooms provide separation from SDSA instrumentation and trip logic.

In Units 5-8, the Unit Emergency Control Centres contain the unit controls and logic panels associated with the following systems:

- SDS2
- Emergency Water Supply
- Emergency Power Supply
- Containment
- Plant monitoring systems
- ECI Recovery System (controls in Units 5 and 7 Unit Emergency Control Centre only)
- Filtered Air Discharge System (controls in Unit 5 Unit Emergency Control Centre only)

When the main control centre is not available for any reason, the reactor can be safely shut down and maintained in that state indefinitely from the Unit Emergency Control Centre.

In conclusion, Pickering NGS has the appropriate indications and alarms in the Main Control Room (and in secondary areas should the Main Control Room become uninhabitable) to inform operations staff of mitigating system action and degradation of key plant parameters such that initiating events can be controlled.

D-230 – Preservation of Control Capability

Principle: The Main Control Room is designed to remain habitable under normal operating conditions, anticipated abnormal occurrences and accidents considered in the design. Independent monitoring and the essential capability for control needed to maintain ultimate cooling, shutdown and confinement are provided remote from the Main Control Room for circumstances in which the Main Control Room may be uninhabitable or damaged.

Provisions for Main Control Room habitability during normal operation and following an accident are in place for both Units 1,4 and Units 5-8.

Precise control of space temperature and humidity is required at all times to provide the necessary environment for computing and other solid state equipment as well as for the comfort of occupants. During normal operation, cooling of the Main Control Rooms and Control Equipment Rooms is maintained at all times to offset heat generation from lighting, equipment and staff.

As part of the Environmental Qualification retrofit to improve mitigation of powerhouse harsh environment events, modifications were made that included a Powerhouse Emergency Venting System that promotes a flue effect to sweep steam out of the building and protect the Main Control Room.

An enclosure for the air-conditioning equipment located on the 294 ft. elevation maintains Main Control Room conditions in the first 10 minutes following a postulated steam line failure in the Units 5-8 powerhouse or reactor auxiliary bay. The enclosure provides assurance of Control Room habitability in the short-term and survival of the Main Control Room operators so that they can act before evacuation to the Unit Emergency Control Centre.

The air-conditioning equipment in Units 5-8 does not need protection for continuous operation; however, equipment that may provide a leak path into the Main Control Room or Control Equipment Rooms is protected by the enclosure to withstand the environmental conditions caused by the steam line failure. The enclosure limits steam ingress to the extent that the Main Control Room and Control Equipment Room temperature does not exceed 50°C at 100% relative humidity in the first 10 minutes following a steam line release, and withstands a sustained pressure up to 0.1 kPa(d).

Design and procedural changes were performed for Pickering NGS Units 1,4 Restart to provide the following safety functions remote from the Main Control Room, in the event that the Units 1,4 Main Control Room becomes uninhabitable.

- Shut down the reactor and maintain it shut down.
- Remove decay heat.
- Maintain Containment integrity.
- Provide post-accident monitoring of critical safety parameters.

To provide monitoring capability independent of the Main Control Room, the critical safety parameters have been duplicated in the SDSE Instrument Rooms as discussed in Safety Principle D-227, Monitoring of Plant Safety Status. By monitoring critical safety parameters and following critical safety parameter restoration procedures via field actions, it is possible to maintain the Control, Cool, Contain and Monitor safety functions externally from the Main Control Room.

The Unit Emergency Control Centre is an additional control room for each generating unit of Units 5-8. As is discussed in Safety Principle D-227, Monitoring of Plant Safety Status, the Unit Emergency Control Centres provide monitoring and control of key systems external to the Main Control Room. When the Main Control Room is not available for any reason, the reactor can be safely shut down and maintained in that state indefinitely from the Unit Emergency Control Centre. Each Unit Emergency Control Centre is required to be accessible, operational and habitable following any event requiring operator action in the Unit Emergency Control Centre. On that basis, the following are the Unit Emergency Control Centre room criteria:

- Self-contained operation
- Immunity from events that may disable the Main Control Room
- Independence from the equipment in the Main Control Room
- Independence from normal plant service systems

A seismically qualified emergency lighting system is provided in the four Unit Emergency Control Centres, the Emergency Water and Power System Building, the four Emergency Water System booster pumphouses, the Filtered Air Discharge Building, the areas in the Reactor Auxiliary Bay beside the ECI System recovery pumps, and the escape route from the Main Control Room to outside the powerhouse below the Pressure Relief Duct.

In conclusion, the Main Control Rooms in Pickering NGS are designed to remain habitable during normal operation and postulated DBAs. Should a Main Control Room become uninhabitable, the SDSE Instrument Rooms in Units 1,4 and the Unit Emergency Control Centres in Units 5-8 are designed to inform operations staff of key plant parameters and allow for critical safety system action to be initiated.

M&C-246 – Safety Evaluation of Design

Principle: Construction of a nuclear power plant is begun only after the operating organization and the regulatory organization have satisfied themselves by appropriate assessments that the main safety issues have been satisfactorily resolved and that the remainder are amenable to solution before operations are scheduled to begin.

Prior to the construction of Pickering NGS, relevant knowledge and experience with respect to licensing and operating the CANDU design had been acquired through the Nuclear Power Demonstration and Douglas Point projects. The construction of both Units 1-4 and Units 5-8 was initiated and completed in accordance with the applicable regulatory requirements. As part of the pre-construction and construction licensing process, assessments were submitted to the regulator demonstrating that safety issues were resolved or amenable to resolution.

Design and operating improvements that have been implemented in Units 1,4 and Units 5-8 in response to OPEX and other emerging issues are documented in the respective Safety Reports and Probabilistic Safety Assessments, together with the safety features of the original plants. Experience subsequent to the initial operation of Units 1-4 and Units 5-8 has shown that, whenever a safety issue has been identified, it has been dealt with effectively. This has occurred due to the infrastructure and processes in place, allowing for sufficient flexibility to address emerging issues. An example is the provision of Emergency Mitigating Equipment in Units 1,4 and Units 5-8 for mitigation of BDBAs.

In conclusion, processes are in place to prevent or address any safety issues that may arise. Note that this safety principle, with its reference to “main safety issues” identified during the plant construction period, is intended for the stage prior to operation of the plant. In the spirit of the PSR2 assessment for the extended operating period, the emphasis for the current review is on safety evaluation relevant to continuing operation.

M&C-249 – Achievement of Quality

Principle: The plant manufacturers and constructors discharge their responsibilities for the provision of equipment and construction of high quality by using well proven and established techniques and procedures supported by quality assurance practices.

Design and quality assurance processes were put in place for design analysis, stress analysis, material control and traceability, fabrication, in-process inspection, installation and welding, control of weld quality, non-destructive examination and inspection. Meeting nuclear industry standards requires that suppliers have a level of quality assurance commensurate with the nature and application of the goods being supplied. These standards formed the basis of the series of Canadian National Standards initially issued in the 1970's under the Nuclear Standards Steering Committee. They were found useful in other industries and were taken over by the Quality Standards Steering Committee. Later, the international community decided that these standards and similar ones in other countries should be harmonized. Using these as the basis, the ISO produced ISO 9000, now used extensively in a wide range of industries around the world. In September 2016, the CSA N299 series of standards was issued to update the quality assurance program requirements for the supply of items and services for nuclear power plants. The CSA N299 standards are outside the scope of the PSR2 since they postdate the PSR2 documentation freeze date of January 15, 2016.

The design management program specifies requirements for procurement engineering processes ensuring implementation and maintenance of the physical nuclear facilities meet the design basis requirements. The design management program complies with both CSA N286, *Management System Requirements for Nuclear Power Plants*, as well as CSA N285.0, *General Requirements for Pressure-Retaining Systems and Components in CANDU Nuclear Power Plants* and OPG Manual [N-MAN-01913.11-10000-R019, *Pressure Boundary Program Manual*, April 5, 2017].

Sections of Pickering NGS governing documents are cross referenced to clauses of CSA N286-12, *Management System Requirements for Nuclear Facilities* in OPG List [N-LIST-08130-10025-R000, *CSA N286-12 to OPGN Governance Cross-Matrix*, September 18, 2015], respectively. The sections of the governance such as OPG Program [OPG-PROG-0009-R002, *Items and Services Management*, May 15, 2015] also contain cross references to the applicable clauses of CSA N286-12. There are many programs and procedures that control purchasing of equipment and services where this affects plant safety.

The processes identified in OPG-PROG-0009-R002, *Items and Services Management*, ensure that items, services and nuclear Fuel are purchased in accordance with stated requirements and controlled through proper identification, handling, storage, issuance and shipping to ensure that the quality of equipment and components is preserved.

The controls for establishing and maintaining the OPG Approved Supplier List are documented in OPG Procedure [N-PROC-MM-0010-R021, *Establishing And Maintaining Ontario Power Generation Approved Suppliers List*, February 1, 2017]. N-PROC-MM-0010-R021 describes the methods used to originate, request, evaluate, qualify and maintain the qualification of suppliers of items and services.

To summarize, the design and construction of Pickering NGS was undertaken under an industry-leading quality assurance regime. Currently, design modifications are performed in compliance with rigorous quality assurance requirements aligned with current regulatory requirements and industry best practices.

C-255 – Verification of Design and Construction

Principle: The commissioning programme is established and followed to demonstrate that the entire plant, especially items important to safety and radiation protection, has been constructed and functions according to the design intent, and to ensure that weaknesses are detected and corrected.

The Pickering NGS commissioning program was conducted to demonstrate that each unit and the overall station functions as designed. The effectiveness of the commissioning program is borne out by the record over several decades of safe operation of both Units 1,4 and Units 5-8.

Currently and in the period of extended operation, verification of effectiveness is, or will be, required for any changes in plant SSCs. OPG Program [N-PROG-MP-0009-R012, *Design Management*, May 12, 2017] requires that design changes are initiated, implemented and tracked in accordance with OPG Program [N-PROG-MP-0001-R015, *Engineering Change Control*, May 12, 2017]. The primary objective of the engineering change control program is to ensure that all modifications to plant SSCs, including software and station engineered tooling, are planned, designed, installed, commissioned, decommissioned, placed into service or removed from service within the SOE, design basis and plant licensing conditions.

It is concluded that design verification of design modifications is ensured by engineering change control.

C-258 – Validation of Operating and Functional Test Procedures

Principle: Procedures for normal plant and systems operation and for functional tests to be performed during the operating phase are validated as part of the commissioning programme.

Validation of the planned operating procedures and for testing to be performed during operation was carried out during commissioning. The effectiveness of the commissioning program is borne out by the record over several decades of safe operation of both Units 1,4 and Units 5-8.

All new procedures and major revisions to existing procedures are validated either in the simulator or in the field per OPG Procedure [N-PROC-AS-0028-R018, *Development Review*

And Approval Of Technical Procedures, February 9, 2017]. The completion of applicable validation activities is consistent with industry best practice. The validation process ensures that documents are correct, meet the intended function and are usable by a qualified individual. The method selected for technical procedure validation depends on various considerations such as the complexity of the document, availability of a suitable validation site and the number of disciplines involved in the performance of the tasks. Validation methods include the following:

- **Field Validation:** A validation method that requires tasks specified in the technical procedure be performed on actual plant equipment.
- **Simulated Performance Validation:** A validation method that requires tasks specified in the technical procedure be performed on simulators, models, mock-ups or on shop equipment that is not considered to be plant equipment.
- **Table-Top Discussion and Walk Through:** A validation method that requires instructions in the technical procedure be talked through step-by-step followed by the steps being walked through in the normal work environment.

Irrespective of the validation method selected for a given procedure, the validation process requires involvement from staff who will be using the procedure, once it is approved. The procedure author addresses feedback from the validation process and obtains concurrence from individual validators on the dispositions to their comments.

In summary, there are robust processes in place to validate any proposed change in operating procedures at Pickering NGS.

C-260 – Collection of Baseline Data

Principle: During commissioning tests, detailed diagnostic data are collected on components having special safety significance and the initial operating parameters of the systems are recorded.

During the initial commissioning of Pickering NGS, data were collected for diagnosing any identified issues and for characterizing the operating conditions of SSCs. Data collection and analysis have been ongoing since operation began. OPG Programs [N-PROG-MA-0017 R009, *Component and Equipment Surveillance*, May 31, 2017] and [N-PROG-MA-0026 R002, *Equipment Reliability*, June 4, 2015] are in place with requirements to continually monitor and trend performance as required.

C-262 – Pre-Operational Adjustment of Plant

Principle: During the commissioning programme, the as-built operating characteristics of safety and process systems are determined and documented. Operating points are adjusted to conform to design values and to safety analyses. Training procedures and limiting conditions for operation are modified to reflect accurately the operating characteristics of the systems as built.

The initial determination of the plant operating characteristics obtained during the commissioning phase allowed for the subsequent safe operation of Units 1,4 and Units 5-8. Operation over several decades has also provided a wealth of data and information that has been used to further optimize how the plant is operated. This is done in accordance with OPG Program [N-PROG-OP-0001-R008, *Nuclear Operations*, December 4, 2015]. The configuration management program is an integrated management process that ensures that:

- Physical and functional characteristics, operation and maintenance conform to the design and licensing basis.
- Operating, training, modification and maintenance processes are consistent with the design and licensing basis conditions.

The limiting conditions for operation are determined and reflected in the SOE, which is reviewed in Safety Principle O-284, Operational Limits and Conditions. As discussed under Safety Principle C-255, Verification of Design and Construction, the commissioning process under [N-PROG-MP-0001-R015, *Engineering Change Control*, May 12, 2017] for new modifications ensures the incorporation of such data going forward.

To summarize, processes are in place to ensure that adjustments of the plant operating conditions are identified, analyzed and implemented if deemed appropriate (e.g., in response to aging of SSCs) to ensure adequate safety margins are maintained.

O-269 – Safety Review Procedures

Principle: Safety review procedures are maintained by the operating organization to provide a continuing surveillance and audit of plant operational safety and to support the plant manager in the overall safety responsibilities.

OPG Program [N-PROG-OP-0001-R008, *Nuclear Operations*, December 4, 2015] establishes safe, uniform and efficient operating practices and processes within OPG Nuclear facilities that provide the operating staff the ability to ensure facilities are operated in such a manner that Power Reactor Operating Licences, Operating Policies and Principles and applicable regulations and standards are followed. The nuclear operations program captures a series of standards and procedures to ensure safety of the public, environment, plant personnel and plant equipment.

OPG Policy [N-POL-0001-R003, *Nuclear Safety Policy*, April 7, 2014] requires that nuclear safety undergoes constant examination. The OPG Charter [N-CHAR-AS-0002-R019, *Nuclear Management System*, November 1, 2016] identifies expectations for the organization to develop priorities based on performance indicators and known challenges.

As described in OPG Procedure [N-PROC-AS-0078-R004, *Nuclear Performance Monitoring And Reporting*, May 22, 2014], the Nuclear Performance Index metric is reported quarterly and is a weighted composite of ten WANO Performance Indicators related to safety and production performance reliability. This metric is one of the many measures used to trend performance and monitor the effectiveness of various improvement programs and allows OPG Nuclear to benchmark against other nuclear plants worldwide.

The Reactivity Management program is routinely assessed and a performance index is used to track performance [N-STD-OP-0009-R011, *Reactivity Management*, January 31, 2017].

Site Event Free Day Resets is reported monthly and reflects the effectiveness of management in reducing human performance events and improving organizational processes. The criteria for application and administration of this metric are conducted in accordance with OPG Instruction [N-INS-09030-10002-R010, *Site And Department Level Event Free Day Resets*, May 1, 2017].

Deficiencies, non-conformances and opportunities to improve a process, document, service or condition are treated as learning opportunities and captured in OPG Program [N-PROG-RA-0003-R010, *Corrective Action*, January 14, 2015]. Individuals are encouraged to identify opportunities to improve and notify appropriate levels of management in order to identify actions to prevent recurrence or improve the process.

External independent reviews provided by a Nuclear Safety Review Board and the Nuclear Oversight Committee of the Board of Directors, as described in OPG Charter [N-CHAR-AS-0002-R019, *Nuclear Management System*, November 1, 2016], provide a review of occurrences and trends that may affect nuclear safety. The Nuclear Safety Review Board, comprised of senior external nuclear experienced individuals, provides the Chief Nuclear Officer with an annual independent assessment of OPG Nuclear activities at each station that may impact nuclear safety and performance. The scope and terms of reference for the operation of the Nuclear Safety Review Board are described in OPG Standard [N-STD-RA-0035-R004, *Nuclear Safety Review Board*, May 25, 2015].

OPG also invites WANO to conduct peer reviews at each OPG Nuclear site every 2 years. An external team of experts reviews all key functional and organizational areas against the WANO Performance Objectives and Criteria. These assessments identify areas for improvement at the host plant and note strengths that could be useful to share with other plants.

In September and October 2016, Pickering NGS hosted an IAEA Operational Safety Review Team (OSART) mission. The OSART review is another example of a safety review conducted by an external peer group.

The Nuclear Executive Committee reviews nuclear safety performance as part of its normal business reviews. This review is fully integrated into the business/operating reports and takes account of related information such as independent evaluations, internal self-assessments and international OPEX.

It is concluded that a variety of safety review procedures are implemented in Pickering NGS to provide a continuing audit and surveillance of plant operational safety.

O-290 – Emergency Operating Procedures

Principle: Emergency operating procedures are established, documented and approved to provide a basis for suitable operator response to abnormal events.

This safety principle is addressed together with Safety Principle O-288, Normal Operating Procedures (Section D.9 of this document) as they constitute a continuum of plant operating procedures.

O-292 – Radiation Protection Procedures

Principle: The radiation protection staff of the operating organization establish written procedures for the control, guidance and protection of personnel, carry out routine monitoring of in-plant radiological conditions, monitor the exposure of plant personnel to radiation, and also monitor releases of radioactive effluents.

Radiation Protection and Regulatory Affairs departments report centrally within the Nuclear Services division. OPG Program [N-PROG-RA-0013-R010, *Radiation Protection*, February 21, 2017] governs the conduct of radiation protection activities and contains cross references to the applicable clauses of CSA N286-05. N-PROG-RA-0013-R010 mandates that "when making engineering changes, engineers maintain or improve upon designs that reduce occupational exposures throughout the lifecycle of the facility". At Pickering NGS, this process is implemented through OPG Standard [N-STD-RA-0018, *Controlling Exposure As Low As Reasonably Achievable*, November 27, 2014].

Per N-PROG-RA-0013-R010, the initial design of the station was created such that the layout and operation of facility SSCs and processes were consistent with the established radiation protection guidelines and contributes to maintaining occupational radiation exposures ALARA. During the initial design of Pickering NGS, emphasis was placed on the reduction of occupational radiation doses. This resulted in design improvements that allowed Pickering NGS and other early CANDU designs to have far less worker exposure to radiation than most other utilities, despite increased staffing needs associated with online fueling, as documented in OPG Report [N-REP-N7250014, *Excellence Through Radiation Protection Practices in Ontario Hydro CANDU-PHW Nuclear-Electric Generating Stations*, September 1, 1987].

Recent improvements in the ALARA strategy include:

- Establishing dose goals for radioactive work to improve individual and station dose performance.
- Use of robotics to perform tasks in radioactive work areas, reducing radiation exposure and therefore dose to workers.

- Use of dynamic learning activities to provide workers an opportunity to practice radiation protection fundamentals in a simulated radioactive work environment using remotely controlled radio technology.
- Implementation of remote reading radiation detection instrumentation and real time data transmission to facilitate improved job planning and awareness of current radiological conditions.
- Implementation of a gamma ray imaging spectrometer to perform enhanced radiation surveys and to identify areas with elevated dose rates, enabling more effective shielding to reduce dose to workers.
- Improved vapour recovery dryer performance.
- Implementation of a reactor face shielding cabinet and other innovative shielding designs to reduce radiation dose rates and, therefore, doses to workers.
- Continued improvements to the provision of remote monitoring and job coverage.

N-PROG-RA-0013-R010 discusses the various procedures and methods used to maintain both exposure control and contamination control at OPG Nuclear facilities, including Pickering NGS. Requirements regarding radiation monitoring instrumentation are primarily discussed in Section 1.5.4, “Hazard Identification and Assessment”, which mandates that all “instruments used for performing surveys are approved by the Health Physics Department to ensure they are appropriate and effective for use in measuring hazards encountered in the station.”

Procedures have been developed for the recording of radiation doses and radioactive effluents. Documentation includes Quarterly Performance Reports. The following are submitted to CNSC per CNSC REGDOC-3.1.1 in accordance with Pickering NGS’s Power Reactor Operating Licence:

- Quarterly Operations Report(s) that include:
  - Worker radiation dose due to events described in S-99 clauses 6.3.1(7) or 6.3.1(8) (superseded by Table A.1 20 b) in REGDOC-3.1.1) and the collective radiation dose of each group of workers.
  - The quantity of radioactive material released in routinely discharged (gaseous and liquid) effluents and hazardous substances.

In conclusion, OPG has implemented a highly effective, well documented and mature Radiation Protection program, based on industry best practices, to keep doses ALARA at Pickering NGS and to monitor releases.

O-299 – Feedback of Operating Experience

Principle: Plant management institutes measures to ensure that events significant for safety are detected and evaluated in depth, and that any necessary corrective measures are taken promptly and information on them is disseminated. The plant management has access to operational experience relevant to plant safety from other nuclear power plants around the world.

OPG Charter [N-CHAR-AS-0002-R019, *Nuclear Management System*, November 1, 2016] establishes the overall requirements for sustaining and improving station performance. In part, this is accomplished by utilizing internal and industry OPEX to improve human, plant, and equipment performance and design, procurement, construction, commissioning, and operating requirements and practices.

Per OPG Program [N-PROG-RA-0003-R010, *Corrective Action*, January 14, 2015], conditions adverse to quality are promptly identified, documented in sufficient detail and reported. Based on the condition report the significance level and resolution category is assigned. The aspect of using OPEX from within OPG Nuclear and the industry is an integral part of this program.

Section 1.4.1 of OPG Procedure [N-PROC-AS-0028-R018, *Development Review And Approval Of Technical Procedures*, February 9, 2017] specifies that for new procedures and major revisions to existing procedures, the preparation stage of the process must involve a review of OPEX lessons learned, event information and just-in-time packages to incorporate applicable information. This ensures that industry best practices are incorporated in the procedure development process.

Section 1.6 of OPG Procedure [N-PROC-OP-0005-R012, *Pre-job Briefing And Post-job Debriefing*, June 6, 2013] provides direction on the use of OPEX during pre-job briefings. The review of OPEX prompts staff to consider any industry best practices which may have emerged since the applicable procedure was last revised or used. Following the execution of the procedure, the post-job debriefing process documented in N-PROC-OP-0005-R012 directs staff to document lessons learned or opportunities for improvement using the appropriate work process (i.e., a Technical Procedure Action Request would be initiated in accordance with N-PROC-AS-0028-R018 to incorporate any procedural improvements/enhancements that were identified during the course of performing the task).

The adequacy of safety-related procedures is also assessed through the ongoing OPEX process described in OPG Procedure [N-PROC-RA-0035-R019, *Operating Experience Process*, September 16, 2016], which monitors events around the world to determine if there is any unforeseen event that may have applicability to Pickering NGS. If/when an event is deemed to be applicable, existing procedures are reviewed to identify any vulnerabilities or weaknesses that could result in similar events or problems with corrective actions initiated as required.

A weekly CANDU Owners Group (COG) OPEX screening meeting, facilitated and administered by COG, serves as an initial screening forum to review event reports from CANDU stations, nuclear industry and non-nuclear sources for applicability and significance to CANDU units. Committee members include representatives from all CANDU facilities (including

Pickering NGS), vendors, research organizations and WANO. Station Condition Records are initiated for items from the screening meeting where a potential vulnerability is identified that is assessed to be applicable to Pickering NGS. Station Condition Records are processed in accordance with OPG Procedure [N-PROC-RA-0022-R034, *Processing Station Condition Records*, March 24, 2017]. An outcome of the Station Condition Record process may include corrective actions to update existing procedures.

Prior to the weekly meeting, the Senior Officer, OPEX screens the recent events at their site, and selects those events that they believe may be of relevance to other sites for review at the COG OPEX Weekly Screening Meeting. On behalf of the utilities, COG provides the initial screening of the international nuclear industry reports and relevant non-industry events.

OPEX representatives at Pickering, Darlington and Nuclear Support each submits relevant OPG significant events to be presented at the COG OPEX Weekly Screening Meeting as per OPG Procedure [N-PROC-RA-0035-R019, *Operating Experience Process*, September 16, 2016]. When potentially significant, these events have been investigated according to OPG Standard [N-STD-RA-0008-R014, *Incident Investigation*, November 16, 2016] and entered into the OPG Station Condition Record process.

Upon completion of the COG OPEX Weekly Screening Meeting, plant OPEX staff in consultation with line staff and/or appropriate OPEX Single Point of Contacts performs a further screening of the Weekly Screening Meeting events from other utilities/non utilities. Items believed to be applicable and actionable at the plant are dispositioned in an Action Request, and if a more significant gap is identified, a Station Condition Record is created and the gap is evaluated according to N-PROC-RA-0022-R034. This process includes not only consideration of potential weaknesses of the plant equipment and operation, but also opportunities for improvement and utilization of research findings.

When an external OPEX item is entered into the electronic Station Condition Record System, it is analyzed by the relevant line department as an OPEX Station Condition Record and processed and stored according to the corrective action program specified in OPG Program [N-PROG-RA-0003-R010, *Corrective Action*, January 14, 2015].

OPG Procedure [N-PROC-RA-0094-R007, *Discovery Issue Resolution Process*, March 21, 2017] is provided to ensure that regulatory limits are maintained by evaluating discovery issues that may impact the SOE. The adequacy of the program for the sending and receiving of experience relevant to safety is monitored and assessed through audits and self-assessments.

In conclusion, Pickering NGS benefits from and effectively implements appropriate modifications arising from comprehensive OPEX feedback programs conducted by the CANDU industry and by OPG as a whole, as well as programs specifically established to identify and assess operational experience within the plant.

O-305 – Maintenance, Testing and Inspection

Principle: Safety related structures, components and systems are the subject of regular preventive and predictive maintenance, inspection, testing and servicing when needed, to ensure that they remain capable of meeting their design requirements throughout the lifetime of the plant. Such activities are carried out in accordance with written procedures supported by quality assurance measures.

As described in [P-CORR-01060-0632223, *Fitness For Service Of Major Components*, February 2017], Major Component aging is managed through a comprehensive program of in-service inspections, maintenance, engineering assessment and confirmatory research and development. These processes provide for the timely detection and mitigation of aging effects in SSCs that impact plant safety, reliability and economics; thereby providing a decision making process to optimize asset management. Regular preventive and predictive maintenance, inspection, testing and servicing of SSCs important to safety and reliability are conducted in accordance with OPG Programs [N-PROG-MA-0026-R002, *Equipment Reliability*, June 4, 2015], [N-PROG-MA-0004 R011, *Conduct of Maintenance*, April 28, 2015] and [N-PROG-MP-0004 R016, *Pressure Boundary*, November 27, 2015]. These programs are supported by a set of detailed implementing procedures.

OPG Program [N-PROG-MP-0008 R006B, *Integrated Aging Management*, May 2, 2016] ensures that the condition of critical nuclear power plant equipment is understood and that required activities are in place to assure the health of these components and systems while the plant ages. The Integrated Aging Management program covers all critical SSCs having nuclear safety, production, cost, conventional safety and environmental significance. OPG Procedure [N-PROC-MP-0060 R005B, *Aging Management Process*, October 1, 2015] is the predominant method for identifying SSCs to be included in the aging management program.

OPG Program [N-PROG-MA-0017 R009, *Component and Equipment Surveillance*, May 31, 2017] defines requirements for establishing programs to ensure the health of select nuclear power plant components and equipment. This program defines the requirements for establishing component programs that manage component and equipment health including inspection, maintenance and testing.

Major components and structures such as Steam Generators, Fuel and Fuel Channels, Feeder piping and Reactor Components are covered by formal Life Cycle Management Plans and are managed in accordance with N-PROG-MA-0025 R002, *Major Components,* March 25, 2015.

In conclusion, OPG has a robust and multi-faceted SSC inspection program, such that the current condition of the plant is well understood. This provides a solid baseline for the intended operation extension as well as confidence that the requisite data will continue to be acquired going forward. Maintenance programs are aligned with industry best practice and are carried out in accordance with written procedures that are part of the overall management system.

O-312 – Quality Assurance in Operation

Principle: An operational quality assurance programme is established by the operating organization to assist in ensuring satisfactory performance in all plant activities important to plant safety.

OPG Charter [N-CHAR-AS-0002-R019, Nuclear Management System, November 1, 2016] and supporting documents referenced in the Charter, establish the Nuclear Management System for OPG Nuclear, which is compliant with CSA N286-05 and CSA N286-12, and assures that systems, equipment and activities are of the required quality throughout the life of the OPG Nuclear facilities. Supporting organizations and contractors who do not have a quality program approved by the OPG Nuclear organization are required to follow Nuclear Management System requirements.

OPG Standard [N-STD-AS-0020 R014, *Nuclear Management Systems Organizations*, May 19, 2016] outlines the implementation of the OPG Nuclear Quality Program described in N-CHAR-AS-0002-R019. The program is implemented through procedures that are developed, approved, modified and documented through a formal process. There are operating procedures that apply comprehensively to normal, abnormal and emergency conditions (including DBA conditions, post-accident conditions and design extension conditions). These are described in the review of Safety Principle O-288, Normal Operating Procedures, which also addresses Safety Principle O-290, Emergency Operating Procedures.

OPG Standard [N-STD-AS-0023-R008, *Nuclear Safety Oversight*, September 15, 2015] describes independent assessment (external and internal) processes used for oversight and assessment of OPG Nuclear safety. Internal independent assessments are performed by Supply Chain, Nuclear Waste Management and Nuclear Oversight. Nuclear Oversight audits are conducted in accordance with OPG Procedure [N-PROC-RA-0048-R018, *Conducting Performance Based Audits and Assessments*, April 28, 2016]. External independent assessments are performed by the Nuclear Safety Review Board in accordance with OPG Standard [N-STD-RA-0035-R004, *Nuclear Safety Review Board*, May 25, 2015]. Audits are carried out at frequencies determined through risk-based assessments, with sufficient frequency to confirm conformance with the quality assurance program and related programs, procedures and instructions. Audit frequency ranges from one to five years, depending on results of the risk based frequency assessment documented in the Nuclear Operations Assurance Map. Objectives of N-PROC-RA-0048-R018 include identification and documentation of conditions adverse to quality in accordance with OPG Program [N-PROG-RA-0003-R029, *Corrective Action*, January 14, 2015], verification of compliance and effectiveness of the pressure boundary quality assurance program, as well as verification of compliance and effectiveness of the quality assurance manual for testing and repairing relief valves.

Quality assurance records are defined in OPG Procedure [OPG-PROC-0179-R001, *Nuclear Quality Assurance Records*, March 14, 2016] as essential records providing evidence of licensing, design, construction, operation, maintenance, testing and modification of OPG Nuclear facilities.

OPG Program [N-PROG-OP-0001-R008, *Nuclear Operations*, November 13, 2015] establishes safe and efficient operating practices and processes within OPG Nuclear facilities that provide operating staff the ability to ensure facilities are operated in such a manner that Power Reactor Operating Licences, Operating Policies and Principles and other applicable regulations and standards are followed.

To summarize, Pickering NGS operation is supported by a comprehensive and effective quality assurance program. Operation of the Pickering NGS units is conducted in compliance with rigorous quality assurance requirements.

D.4. Safety Principles Related to Levels 1, 2, 3

The following safety principles are related to defence-in-depth Levels 1, 2, 3:

- D-192 – Protection Against Power Transient Accidents
- D-195 – Reactor Core Integrity
- O-278 – Training
- O-284 – Operational Limits and Conditions

As demonstrated below, Pickering NGS design and operation are aligned with all safety principles related to Levels 1, 2, 3.

D-192 – Protection Against Power Transient Accidents

Principle: *The reactor is designed so that reactivity induced accidents are protected against, with a conservative margin of safety.*

In Pickering NGS Units 1,4 and 5-8, the neutronic characteristics provide inherent protection against a reactivity induced accident. The use of natural uranium Fuel, on-power refuelling and a heavy water Moderator leads to a design characterized by good neutron economy and low excess reactivity. The reference lattice pitch is optimum in the sense that an increase or decrease of the lattice pitch would reduce reactivity.

In the Pickering NGS design, all reactivity rods for control and shutdown are introduced into guide tubes positioned in the low-pressure Moderator. These guide tubes are located interstitially between rows of Calandria tubes.

Units 1,4 and 5-8 Reactor Regulating Systems automatically control power and reactivity. A setback function within the Reactor Regulating System reduces power upon detection of parameters outside prescribed normal limits.

The Pickering NGS Units 5-8 design includes the stepback feature of the Reactor Regulating System, which can control reactivity induced accidents. Stepback occurs by dropping four control absorbers into the core on detection of high neutron power or high log rate of neutron power. Units 5-8 have two fast-acting Shutdown Systems with neutronic trip parameters that are able to mitigate rapid reactivity transients as well as slow transients. In Units 1,4, the Shutdown Systems SDSA and SDSE both employ the same set of shutoff rods, but have independent neutron overpower and high log neutron rate detection and trip logic. SDSA also has a high linear neutron rate trip parameter. SDSE has a distributed Neutron Overpower trip parameter. For these accidents, as well as for other transients, the Shutdown Systems incorporate diverse trip parameters for each accident scenario.

Safety analyses documented in Part 3, Appendix 3 of the Pickering NGS Safety Reports [NA44-SR-01320-00002-R004, *Pickering Nuclear 1-4 Safety Report: Part 3 – Accident Analysis*, October 31, 2013] and [NK30-SR-01320-00003-R004, Vol. 2, *Pickering Nuclear 5-8 Safety Report Part 3 – Accident Analysis*, October 30, 2014] demonstrate the effectiveness of the Shutdown Systems in mitigating reactivity induced accidents. Further description of the Shutdown Systems is provided in the review of Safety Principle D-200, Automatic Shutdown Systems.

To summarize, Pickering NGS has been designed with a focus on protection against reactivity-induced transients, specifically through highly reliable and effective reactor Shutdown Systems.

D-195 – Reactor Core Integrity

Principle: The core is designed to have mechanical stability. It is designed to tolerate an appropriate range of anticipated variations in operational parameters. The core design is such that the expected core distortion or movement during an accident within the design basis would not impair the effectiveness of the reactivity control or the safety shutdown systems or prevent cooling of the fuel.

The Pickering NGS cores (each comprising the reactor and Fuel Channels) have been designed to high standards. Heavy water is contained in the Calandria which envelops the Fuel Channels. Each pressure tube is insulated from the Moderator by a tube surrounding it, but separated from it, by an annular space filled with dry carbon dioxide. This second tube is called the Calandria tube and it is roll expanded at both ends to the flat Calandria tubesheets, thereby completing the Moderator pressure boundary. This configuration results in a low temperature, low pressure design for the Calandria vessel, with the Moderator System being operated independently of the high temperature high pressure heat transport coolant in the pressure tubes. The Calandria operates near atmospheric pressure.

The design, manufacture, installation and inspection of the Calandria assembly comply with the following sections of the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code:

- Section II (Materials Specification)
- Section III (Nuclear Vessels) (1963 edition, unless otherwise indicated)
- Section VIII, Division 1 (Pressure Vessels)
- Section IX (Welding Qualifications)

The Units 1,4 reanalysis of the Calandria assembly, carried out during the large scale Fuel Channel replacement program (Proceedings of CNS Symposium on Advanced Nuclear Services, 1986), was performed in accordance with ASME Code, Section II, Subsection NB, 1983 edition with addenda up to and including winter 1983.

Operating Conditions

The operating conditions have been established for the design purposes of the Calandria assembly. These conditions include:

- Design conditions
- Normal conditions
- Upset conditions
- Emergency conditions
- Maximum allowable stress limit

The allowable stresses are selected on the basis that different types of stresses require different limits.

Cyclic Loading

The design of the Calandria assembly components is based on appropriate combinations of coincident loadings due to temperature, pressure and specific combinations of mechanical loads.

Fuel Channels and Reactor Structures were also designed to meet stringent performance quality requirements. Continued monitoring of these components is performed per the Major Components program [N-PROG-MA-0025-R002, *Major Components*, March 25, 2015]. Pressure Tube design is further discussed under Safety Principle D-209, Reactor Coolant System Integrity.

Postulated initiating events that potentially pose a risk to the structural integrity of the reactor core have been identified and analyzed in the Pickering NGS Safety Reports. Analyses of postulated in-core LOCA documented in Part 3, Appendix 4 of the Safety Reports [NA44-SR-01320-00002-R004, *Pickering Nuclear 1-4 Safety Report: Part 3 – Accident Analysis*, October 31, 2013] and [NK30-SR-01320-00003-R004, Vol. 2, *Pickering Nuclear 5-8 Safety Report Part 3 – Accident Analysis*, October 30, 2014] have demonstrated that the damage to in-core components will not result in failure of any other Fuel Channel or of the Calandria vessel. In addition, the reactivity depth provided by the shutoff rods sufficiently delays re-criticality of the reactor for the most limiting operating state.

In summary, the integrity of the Pickering NGS core for the range of normal operation and accidents within the design basis is assured through high quality design and operation, and is demonstrated by comprehensive assessments and analyses.

O-278 – Training

Principle: Programmes are established for training and retraining operations and maintenance, technical support, chemistry and radiation protection personnel to enable them to perform their duties safely and efficiently. Training is particularly intensive for control room staff, and includes the use of plant simulators.

OPG has adequate staff training facilities, training staff and training programs, and has the oversight to confirm this. The training program requirements apply to all disciplines, including operations and maintenance, technical support, chemistry and radiation protection. [N-TQD-601-00001-R017, *Leadership and Management Training and Qualification Description*, April 4, 2015] provides qualification and professional development requirements for supervisors and managers which includes Safety Culture for Managers. OPG Program [N-PROG-TR-0005-R016, *Training*, January 5, 2016] describes the training program for regular staff, contractors, temporary personnel and other staff assigned work at OPG Nuclear. It includes the structure, processes and tools for defining, developing, implementing, documenting, assessing and improving the training required to ensure OPG Nuclear staff have the appropriate knowledge, skill and attitudes for safe and efficient plant operation.

As described in Section 1.6.3 of [P-CORR-00531-03719, *Application for Renewal of Pickering Nuclear Generating Station Power Reactor Operating Licence*, July 4, 2012], OPG identifies qualified and competent individuals for key positions. With career development and succession planning being key elements in the management capability strategy, a Corporate Succession Plan ensures that individuals with high leadership potential are identified.

OPG Procedure [N-PROC-TR-0002-R008, *Control of Vendor-Supplied Training*, October 14, 2016] establishes requirements, process and accountabilities for control of training developed by vendors and training delivered by vendors within OPG Nuclear premises and externally. This procedure addresses the following:

- Vendor instructor capabilities and qualifications to instruct OPG Nuclear staff.
- Requirements for review, verification and acceptance of vendor-supplied training prior to and after training delivery.

Similarly, training and qualification description documents are also available for operations and maintenance staff. OPG List [N-LIST-08920-10001-R008, *Trained Performance Areas*, March 2, 2016] identifies the list for trained performance jobs (i.e., performance areas in the training program), and supporting Qualification Guides reside within the framework of OPG Procedure [N-PROC-TR-0021-R011, *Training and Qualification Description Development and Approval Process*, June 24, 2016].

N-PROC-TR-0021-R011 provides requirements for developing, approving, revising and implementing the Training and Qualification Documents and Qualification Guides. The Training and Qualification Documents and the Qualification Guides document entry-level, initial and continuing training requirements. Training and Qualification Documents contain details of training stages and requirements for each stage as follows:

- **Initial Training:** Introduce and develop job related knowledge, skills and performance standards, preparing personnel to independently perform assigned duties and tasks.
- **Continuing Training:** Used to maintain and enhance knowledge and skills, and address areas such as plant equipment and procedure changes, infrequently used and difficult skills, knowledge and skills weaknesses, and lessons learned from OPEX. Continuing training may also provide refresher type training at a specified frequency, and may be required to maintain qualified status.

Training and Qualification Documents and Qualification Guides include but are not limited to:

- Authorized Nuclear Operator
- Control Room Shift Supervisor
- Health Physicist
- Maintenance

Training specifically for radiation protection staff is governed by several documents, including [N-TQD-502-00001-R018, *Nuclear Radiation Protection Training and Qualification Description*, October 27, 2014].

Continuing training is developed in accordance with OPG Instruction [N-INS-08920-10021-R001, *Continuing and Requalification Training – Curriculum Development and Implementation Process*, September 13, 2016]. Annual continuing training requirements, including impact on qualification status, are presented in the corresponding Training and Qualification Document. These requirements include reference to any existing Continuing Training Plan. The continuing training meets the needs of both refresher and upgrade training.

Training, qualification for, and certification for Main Control Room staff and for field positions ensure that the staff are competent to perform the functions assigned to them. The simulator is used extensively for initial training and qualification, as well as for refresher/requalification training. Per OPG Instruction [N-INS-08920-10002 R007, *Simulator – Based Initial Certification Examinations for Shift Personnel*, August 30, 2016], Simulator Exercise Guides are used as part of training for certified staff. Trainees are assessed per OPG Instruction [N-INS-09110-10059-R004, *Simulator Performance Observation and Crew Critiques*, April 21, 2015].

OPG Instruction [N-INS-08920-10002-R007, *Simulator-Based Initial Certification Examinations for Shift Personnel*, July 19, 2016] provides specific instructions on the application of CNSC-EG2, *Requirements and Guidelines for Simulator-based Certification Examinations for Shift Personnel at Nuclear Power Plants*, for initial CNSC certification, which includes:

- Process for planning, developing, conducting and grading simulator-based certification examinations.
- Examination follow-up activities including process for dealing with passes and conditional passes.
- Requirements, criteria and guidelines for administering simulator-based initial certification examinations.

N-INS-08920-10001, *Requalification Testing of Certified Shift Personnel* provides requirements for requalification tests that OPG Certified Shift Personnel must successfully complete when seeking renewal of certification. The instruction also identifies processes that OPG follows in developing, conducting and grading written and simulator-based requalification tests which demonstrate that Certified Shift Personnel have retained knowledge and skills required to work competently in their assigned positions.

Training for engineering and technical support staff is discussed in detail under Safety Principle O-296, Engineering and Technical Support of Operations.

It is concluded that the training program for Pickering NGS operations, maintenance and technical support staff is comprehensive and ensures that staff are properly trained for their assigned duties.

O-284 – Operational Limits and Conditions

Principle: A set of operational limits and conditions is defined to identify safe boundaries for plant operation. Minimum requirements are also set for the availability of staff and equipment.

The SOE is the set of limits and conditions within which the plant shall be operated to ensure conformance with the Safety Reports and that the Safety Report conclusions remain valid. OPG Standard [N-STD-MP-0016-R002, *Safe Operating Envelope*, June 21, 2012] provides requirements for defining, implementing and maintaining the SOE. The specific objectives of the SOE are to establish the following:

- Thorough and current record of safety credits and operating limits in the form of operational safety requirements. Safe Operating Limits and Conditions of Operability (SOE Limits) are captured in station operating documentation, which provide plant operators with the information required to ensure safe operation of the plant in conformance with the requirements of the Safety Analysis.
- A compliance framework whereby plant operation within the requirements established as part of the SOE is verified on a regular basis and appropriate corrective actions are implemented.
- Infrastructure by which the SOE is integrated with other relevant business processes and maintained current over the life of the station.

SOE systems are listed in OPG Instruction [N-INS-03602-10001-R001, *Preparation of Safe Operating Envelope Compliance Tables*, February 11, 2015] and are identified in N-STD-MP-0016-R002. These SSCs include systems and their associated critical components and structures, for which operational safety requirements are specified to conform to the Pickering NGS Safety Reports and hence, the safety analysis. OPG has prepared formal operational safety requirement documents in support of SOE systems. The SOE systems and associated operational safety requirements are listed in OPG instruction N-INS-03602-10001-R001 and are also listed in the Licence Conditions Handbook [P-CORR-00531-04886, *Pickering NGS: Licence Conditions Handbook, LCH-PNGS-R005*, November 10, 2016].

The methodology for the preparation and revision of operational safety requirement reports is described in [N-ST-08131.02-10000-R02, *Preparation of Operational Safety Requirements*, December 22, 2014]. The operational safety requirement reports contain the following information (as outlined in Section 1.2.4 of N-STD-MP-0016-R002):

- A brief overview of the safety functions of the system in relation to the DBA for which it is credited.
- Safety limits defining the acceptable standards with respect to component or parameter performance.
- Surveillance requirements identifying specific objectives of tests or checks to ensure plant operation within the defined Safety Limits.
- Conditions of Operability defining the impact on overall availability of the system or safety function in the event of operation outside of the defined Safety Limits.

OPG Standard [N-STI-03602-10000-R001, *SOE Instrument Uncertainty and Allowable Value Calculations*, October 07, 2011] describes the methodology for the preparation and revision of Instrument Uncertainty Calculation Reports. The Instrument Uncertainty Calculation Reports contain calculations for applicable instrumentation loops (as outlined in Section 1.2.7 of N-STD-MP-0016-R002).

As per Section 1.3.2 of N-STD-MP-0016-R002, information contained in the operational safety requirement and Instrument Uncertainty Calculation Reports are incorporated into affected station operating documentation (e.g., Operating Manuals, Abnormal Incident Manuals, Safety Related System Tests and the preventive maintenance program) in accordance with OPG Instruction [N-INS-03602-10001-R001, *Preparation of Safe Operating Envelope Compliance Tables*, February 11, 2015].

To ensure effective monitoring (e.g., ensuring SSC compliance with design requirements and specifications), maintenance and enhancement of system performance and reliability, OPG Procedure [N-PROC-MA-0024-R016, *System Performance Monitoring*, December 09, 2016] provides a consistent and comprehensive process for system engineers.

The process for identifying and evaluating degraded station conditions when the ability of SSCs to carry out their defined safety-related functions is questioned is described in the technical operability evaluation process in OPG Procedure [N-PROC-MP-0045 R008, *Technical Operability Evaluation*, September 15, 2015]. The process provides for engineering verification that a SSC is capable of fulfilling its minimum credited safety function(s). It is required when uncertainty arises with respect to operability of equipment to meet the functional requirements of the defined SOE, and is initiated concurrently with a Station Condition Record.

OPG Instruction [P-INS-09100-00003-R010, *Pickering Minimum Shift Complement*, April 13, 2017] defines the minimum shift complement staffing requirements to ensure that safe conditions are maintained during normal operations along with the capability to be able to respond to all station emergencies. Per OPG Instruction [P-INS-09260-00008-R008, *Duty Crew Minimum Complement Assurance*, April 10, 2017], minimum shift complement is the minimum number of qualified workers who shall be present at all times to ensure the safe operation of the Pickering units, respond to all credible events and ensure adequate emergency response capability for the most resource intensive conditions. P-INS-09100-00003-R010 is written to comply with CNSC G-323*, Ensuring the Presence of Sufficient Qualified Staff at Class I Nuclear Facilities – Minimum Staff Complement* and CNSC G-278, *Human Factors Verification and Validation Plans*.

P-INS-09260-00008-R008 defines the responsibilities and processes to ensure that the minimum shift complement according to P-INS-09100-00003-R010 is met, as well as the correct use and updating of the local area network based minimum complement compliance program, which is used to ensure minimum shift complement is met. The instruction defines: actions required when below complement, duty crew accounting, absence reporting, “step-up” (i.e., designating a temporary change in work group or Emergency Response Organization assignment), minimum availability requirement, emergency role qualification and position assignments.

To summarize, operational limits and conditions for Pickering NGS are clearly defined and justified based on appropriate safety analyses. Procedures are in place to ensure that the plant is operated within the applicable limits. Minimum requirements are also set for the availability of staff and equipment.

D.5. Safety Principles Related to Levels 3, 4, 5

There is one safety principle related to defence-in-depth Levels 3, 4, 5:

- EP-339 – Assessment of Accident Consequences and Radiological Monitoring

As demonstrated below, Pickering NGS design and operation are aligned with the safety principle related to Levels 3, 4, 5.

EP-339 – Assessment of Accident Consequences and Radiological Monitoring

Principle: Means are available to the responsible site staff to be used in early prediction of the extent and significance of any release of radioactive materials if an accident were to occur, for rapid and continuous assessment of the radiological situation, and for determining the need for protective measures.

Response and mitigation strategies for accidents that release significant radioactivity to the environment are developed in accordance with the deterministic safety analysis and with insights from the PSA. In addition, the Emergency Response Projection computer code is a tool used to assist in decision-making for off-site emergency response protective actions. Emergency Response Projection is an analysis-like code that uses deterministic methods to evaluate potential offsite consequences and predict the timing of Containment re-pressurization in the event of an accident. OPG and Bruce Power are currently performing a project to enhance their emergency response projection tools. The project is adopting the Unified RASCAL Interface, which is widely used by U.S. utilities.

For continuous assessment of the radiological situation following an accident, OPG Nuclear's emergency facilities are equipped with area radiation monitoring equipment, radiation survey kits, off-site monitoring vehicles and meteorological monitoring data readout equipment, as appropriate to the facility. OPG has also recently installed automated solar-powered Near Boundary radiation monitors around the perimeter of the Pickering site to support radiological monitoring. OPG emergency response facilities are linked to the Provincial Emergency Operations Centre, Municipal Emergency Operations Centre and Regional Emergency Operations Centre through landline phones and other systems to allow information transfer.

It is concluded that prediction tools and monitoring capability have been provided to support emergency response. The ongoing Unified RASCAL Interface project will further enhance the capability to project off-site consequences while an accident is in progress.

D.6. Safety Principles Related to Levels 1, 2

The following safety principles are related to defence-in-depth Levels 1, 2:

- D-164 – Plant Process Control Systems
- D-203 – Normal Heat Removal
- D-209 – Reactor Coolant System Integrity
- D-240 – New and Spent Fuel Storage

As demonstrated below, Pickering NGS design and operation are aligned with all safety principles related to defence-in-depth Levels 1, 2.

D-164 – Plant Process Control Systems

Principle: Normal operation and anticipated operational occurrences are controlled so that plant and system variables remain within their operating ranges. This reduces the frequency of demands on the safety systems.

The major control loops and their basic functions in Units 1,4 (Units 5-8 equivalent in parentheses, if different) are:

1. The Reactor Control System monitors and operates the reactivity control devices to maintain a desired power level and neutron flux shape. The reactor power can be specified by the operator or by Steam Generator pressure control depending on the mode of unit control. There is a reactor power setback facility to keep plant parameters within pre-determined values during abnormal conditions.
2. The Steam Generator pressure control loop manipulates the turbine load setpoint or steam reject valves to maintain the steam pressure setpoint.
3. The turbine-generator control (unit power regulator) loop performs loading of the turbine/generator and provides monitoring of the turbine and generator.

4. The Steam Generator level control loop manipulates the feedwater valves to maintain the water level in the Steam Generator at a level setpoint dependent on reactor power.
5. The heat transport pressure control loop controls the heavy water feed and bleed valves to maintain a constant heat transport pressure.

The Reactor Control System provides a high degree of immunity to process upsets, measurement failures, etc., due to a high degree of redundancy in control devices and process measurements. Extensive checks are performed in the programs to ensure that faulty signals are discarded. In case of loss of an entire set of signals, control is transferred to the standby computer. The ability to maintain control in the presence of partial system failures, combined with high reliability of the Dual Computer Control System, leads to a very high availability of the Reactor Regulating System.

The normal method of shutting down the reactor is by means of the Reactor Regulating System. During plant upsets or potentially undesirable operating conditions, the reactor is shut down or derated automatically by the reactor setback function of Reactor Regulating System (Units 5-8 includes setback and an additional stepback function).

The computer system reduces reactor power setpoint in a ramp fashion when a setback signal is received from triplicated setback relay logic. A setback signal is generated by certain plant conditions. Reactor power is reduced at a controlled rate until either the setback signal clears or the power is reduced to a specified low value.

In the event that the turbine cannot accept all the steam generated, the Boiler Pressure Control system operates the steam reject valves. When the large steam reject valves are opened the reactor will setback. This setback will terminate if the large steam reject valves close or if the operator intervenes.

It is concluded that the control systems in Pickering NGS have been designed to maintain the reactor operating conditions within the normal operating range, and to effectively respond to anticipated transients to avoid the need for safety system action.

D-203 – Normal Heat Removal

Principle: Heat transport systems are designed for highly reliable heat removal in normal operation. They would also provide means for the removal of heat from the reactor core during anticipated operational occurrences and during most types of accidents that might occur.

In normal operation, heat is removed from the Fuel to the Steam Generators by the forced flow of coolant in the Heat Transport System. Steam generated in the Steam Generators is condensed in the condenser by the Condenser Cooling Water System, which rejects the heat to the ultimate heat sink, Lake Ontario (see Safety Principle S-142, Ultimate Heat Sink Provisions).

Reactor startup after a maintenance outage requires that verification of flow in individual Fuel Channels be performed. During normal operation, resistance temperature detectors in outlet Feeders provide a continuous means of monitoring for major flow blockages in any channel.

During fuelling, monitoring of the channel outlet temperature provides the operator with an indication of a flow blockage in the Fuel Channel being refuelled. As a result of these design, operational and instrumented alarm features, the occurrence of an undetected flow blockage is very unlikely.

In the event of a partial or total loss of forced flow in the Heat Transport System, heat removal from the Fuel to the Steam Generators is maintained.

In Units 1,4, two small and six large Steam Reject Valves discharge steam from the main steam line if the turbine becomes unavailable. The two small valves discharge steam to the forebay when the reactor is warmed up and the six large valves discharge to atmosphere. Rapid shutdown of the turbine causes all the steam reject valves to open. The steam reject valves are also sized to pass the quantity of steam produced by the reactor. The Units 5-8 design is similar, except that there are 10 large Steam Reject Valves in these units.

For events involving a loss of Steam Generator inventory (steam main break or loss of feedwater), qualified backup boiler water supplies are available to remove the decay heat generated in the Fuel. In the short term, the Boiler Emergency Cooling System provides water to Units 1,4 and Units 5-8 for reactor decay heat removal by the boilers for accident situations initiated by or leading to failure of the normal feedwater supply. The Boiler Emergency Cooling System is qualified to Design Basis Earthquake Category B. For long-term cooling, the Emergency Boiler Water Supply system is designed to provide emergency water to the boilers of Units 1,4 following a postulated main steamline failure within the Units 1,4 powerhouse. It is also capable of providing water to the boilers for a total loss of feedwater event. The Emergency Boiler Water Supply System is supplied from the discharge headers of the Units 6 and 7 High Pressure Service Water System. In Units 5-8 in the longer term, the shutdown cooling system is initiated manually to provide the heat sink for the Heat Transport System. In addition, the Emergency Water System is a seismically qualified system supplying long-term emergency makeup to the boilers, Heat Transport System, ECI recovery heat exchangers, Containment air coolers and the Moderator.

The ECI System is designed to refill the Heat Transport System following a LOCA, and to provide coolant makeup and the heat sink in the long term via the ECI heat exchangers.

For additional information on emergency heat removal see Safety Principle D-207, Emergency Heat Removal.

In summary, Pickering NGS Units 1,4 and Units 5-8 are equipped with heat removal systems that effectively and efficiently remove heat from the Fuel under normal operating conditions. These systems are also effective in response to anticipated transients and accidents within the design basis, supplemented by the emergency makeup water systems included in the design.

D-209 – Reactor Coolant System Integrity

Principle: Codes and standards for nuclear vessels and piping are supplemented by additional measures to prevent conditions arising that could lead to a rupture of the primary coolant system boundary at any time during the operational lifetime of the plant.

The CSA N285 series of Standards specifies requirements for nuclear vessels and piping applicable to nuclear power plants in Canada and references the applicable requirements of the ASME Boiler and Pressure Vessel Code. Compliance with CSA N285.0-08, *General Requirements For Pressure-Retaining Systems and Components in CANDU Nuclear Power Plants*, (including Updates No. 1 and No. 2), is currently a licence requirement for Pickering NGS (per PROL 48.03/2018 [PROL 48.03/2018, *Nuclear Power Reactor Operating Licence, Pickering Nuclear Generating Station*]) as indicated in Section 6.2 and Appendix C.1 of the R05 Pickering Licence Conditions Handbook [P-CORR-00531-04886, *Pickering NGS: Licence Conditions Handbook, LCH-PNGS-R005*, November 10, 2016].

CSA N285.0 provides general requirements for pressure-retaining systems, components and supports in CANDU nuclear power plants. It specifies the technical requirements for the design, procurement, fabrication, installation, modification, repair, replacement, testing, examination and inspection of, and other work related to, pressure-retaining systems, components and supports over the service life of a CANDU nuclear power plant.

In Units 1,4, the Feeder piping design has been registered as being in accordance with the ASME B31.1 Power Piping Code. The actual fabrication, testing, material and inspection requirements were in accordance with the historical standard B31.7, *Nuclear Piping for Class 1*. Unit 1 Feeder pipes were subsequently reanalyzed for the large scale Fuel Channel replacement program. The stress analysis was carried out according to the requirements of the ASME Boiler and Pressure Vessel Code, Section III, Subsection NB-3600 (Class 1 Piping), 1983 edition including winter 1983 addenda.

The Feeder supports that were replaced for the large scale Fuel Channel replacement program were analyzed and redesigned to the requirements of ASME Code Section III, Subsection NF, 1983 edition including winter 1983 addenda. These replacement Feeder supports received an Ontario Special Ruling Registration with the Technical Standards and Safety Authority.

The reactor headers are designed and manufactured to the requirements for Class A pressure vessels of Section III of the ASME Code.

In Units 5-8, the heat transport piping, including the headers and Feeders is exclusively seamless carbon steel ASME SA I06 Grade B. The pipe was designed and constructed to the requirements for Class 1 components in Section Ill of the ASME Code, 1974 Edition without Addenda.

The primary side of the Steam Generators is designed and manufactured to the requirements for Class 1 components in Section Ill of the ASME Code.

In Units 1,4 and Units 5-8, the pressure tubes are classified as Class 1 nuclear components. The zirconium-niobium alloy is not an ASME Code material but the design stresses are based on the factors of safety specified by ASME Section Ill. The wall thickness calculations were conducted using the methods set out in ASME Section Ill and a corrosion and wear allowance of 0.20 mm (0.008 in.) was provided. Zirconium alloys are covered by CSA standard CAN/CSA N285.6. The cold-worked Zr-2.5 Nb alloy was therefore fabricated and tested to meet the requirements of AECL Specification [TS-XX-31110-5, Rev. 2, *Cold Worked Zirconium – 2.5 wt% Niobium Extruded and Drawn Pressure Tubes*, May 1976] and surface conditioned and stress relieved to AECL Specifications [TS-XX-31110-4, Rev. 05, *Cleaning and Stress Relief of Cold Worked Zirconium – 2.5 wt% Niobium Pressure Tubes*, March 29, 1979] or TS-XX-31110-8.

Knowledge and experience gained over many reactor-years of operation and research and development have demonstrated that pressure tube failure will be preceded by a period of leakage (leak-before-break). The Annulus Gas System has provisions for monitoring the moisture content of the annulus gas, which can provide an early indication of a pressure tube leak and allow for reactor shutdown. In Units 1,4, the reliability of the Annulus Gas System beetles was improved by relocating them to an accessible area to facilitate increased testing frequency. Also, a drains tank was added to monitor the collection rate of water condensed by the cooling coil and to alarm at a collection rate of 2 kg/h. Units 5-8 also have accessible Annulus Gas System beetles and a drains tank that is manually monitored.

Protection against overpressure for the Heat Transport System circuit is provided by the combined effects of pressure relief valves and the reactor Shutdown System. Two instrumented control valves in each loop function as pressure relief valves. Overpressure protection for the Heat Transport System is provided by four instrumented pressure relief valves (two connected to the north loop and two to the south loop) which relieve to the bleed condenser. While two valves are sufficient to relieve the pressure, 200 per cent relief capacity has been provided.

Life Cycle Management Plans described in the reviews of Safety Principles D-186, Inspectability of Safety Equipment, and O-305, Maintenance, Testing and Inspection, ensure ongoing compliance of the components relevant to Reactor Coolant System integrity with the design codes and standards.

In conclusion, the Pickering NGS Heat Transport System is designed to avoid pressure boundary failure through high-quality design and maintenance, provision of adequate pressure relief capability and comprehensive leak detection capability. Confidence in the integrity of the pressure boundary is supported through appropriate assessments and research and development.

D-240 – New and Spent Fuel Storage

Principle: Plant designs provide for the handling and storage of new and spent fuel in such a way as to ensure protection of workers and to prevent the release of radioactive material.

A lattice of natural uranium and light water cannot be made critical in any configuration. Hence, no criticality problem exists in handling new Fuel or in the IFB of CANDU reactors.

The degree of automation of the fuel handling design in Pickering NGS allows fuel handling to be performed remotely from the operators and contributes significantly to the protection of workers. The reactors are fuelled on-power. Each reactor is serviced by two remotely controlled fuelling machines, one at each reactor face, which, operating at opposite ends of the same Fuel Channel, match Primary Heat Transport System pressure, open the channel and insert fresh Fuel or remove irradiated Fuel, without interrupting reactor operation. Irradiated Fuel is transferred by an elevator and conveyor to the primary IFB where it remains for a minimum of four years before transfer to the Auxiliary IFB. The combined storage capacity of the two bays is designed to accommodate the accumulation of irradiated Fuel.

After an adequate cooling period in the Auxiliary IFB, irradiated Fuel is loaded into dry storage containers, which are transferred for processing and storage to the Pickering Waste Management Facility. The Pickering Waste Management Facility provides sufficient capacity to store the used Fuel generated from the Pickering reactors until the end of the station's service life. The Pickering Waste Management Facility is used for processing and storage of dry storage containers and storage of retube components from Units 1-4 in dry storage modules.

Storage and handling facilities are provided to accommodate bulk storage of new Fuel in the east annex, safe transfer of Fuel to the Reactor Building, inspection of the Fuel in the new Fuel loading areas and easy manual loading of new Fuel bundles into the new Fuel magazines for transfer to the fuelling machines. Suitable handling facilities are provided to avoid damage to the Fuel bundles during manual loading. The new fuel loading area is shielded from those areas likely to contain irradiated Fuel. Personnel are adequately protected from radiation exposure by remote handling of irradiated Fuel in the transfer room and by underwater transport and handling of the irradiated Fuel on the conveyor and in the storage bays. Ventilation and filtration are provided to remove fission products should Fuel be inadvertently damaged during handling.

The storage arrangement with irradiated natural uranium Fuel in light water is well subcritical.

Reliable cooling of the irradiated Fuel in the transfer mechanism magazine is provided by two circulating pumps, one on standby plus an emergency supply from the bay water system. In the event that the elevator carriage should stop in air between its end positions while carrying irradiated Fuel, a cooling water spray system can be activated to prevent overheating of the Fuel. The water spray is supplied from the storage bay systems.

To summarize, Pickering NGS fuel handling has been conducted safely over several decades. Provisions are in place for safe handling of the Fuel from its arrival at the plant through to the IFBs and dry storage.

D.7. Safety Principles Related to Levels 3, 4

The following safety principles are related to defence-in-depth Levels 3, 4:

- D-200 – Automatic Shutdown Systems
- D-207 – Emergency Heat Removal
- D-217 – Confinement of Radioactive Material
- D-221 – Protection of Confinement Structure
- D-233 – Station Blackout

As demonstrated below, Pickering NGS design and operation are aligned with all safety principles related to Levels 3, 4.

D-200 – Automatic Shutdown Systems

Principle: Rapidly responding and highly reliable reactivity reduction for safety purposes is designed to be independent of the equipment and processes used to control the reactor power. Safety shutdown action is available at all times when steps to achieve a self-sustaining chain reaction are being intentionally taken or whenever a chain reaction might be initiated accidentally.

The Shutdown Systems are described in Section 6.1.8 of Part 2 of the Units 1-4 Safety Report [NA44-SR-01320-00001-R016, *Pickering A Safety Report*, July 20, 2017] and in Sections 6.2 and 6.3 of Part 2 of the Units 5-8 Safety Report [NK30-SR-01320-00002 R004, *Pickering B Safety Report – Part 2*, October 15, 2012]. Each system has its own initiation sensors, detectors and logic to ensure functional and physical diversity. The Shutdown Systems are independent of the process systems, such that a process system impairment will have minimal (if any) deleterious impact upon the effective functioning of a Special Safety System.

When Units 1,4 began operation in the early 1970s, its design included a single Shutdown System, which employed two diverse means of inserting negative reactivity into the core:

1. Dropping shutoff rods
2. Dumping the Moderator from the Calandria

To reduce the risk of an uncontrolled reactivity increase event to an extremely low level, CANDU designs subsequent to Pickering NGS Units 1-4 (including Pickering NGS Units 5-8) have incorporated two independent, physically separated and diverse Shutdown Systems. The original Units 1,4 design Shutdown System reliability has been enhanced by retrofitting a Shutdown System Enhancement (SDSE) that provides sensors and trip logic independent from those of the original Shutdown System (SDSA). The additional SDSE trip parameters are heat transport high/low pressure, neutron overpower, high neutron log rate and manual trip. In addition to initiating the shutoff rod drop, SDSA and SDSE are both augmented by the Moderator dump feature (see above). The design of SDSA and SDSE is such that they are independent of each other from trip sensing to the final relay contacts in the shut-off rod drop logic and the Moderator dump logic (i.e., they do not include the shut-off rod clutch mechanisms or the Moderator dump valves). The adequacy of the Shutdown System design in limiting the risk of an uncontrolled reactivity increase is demonstrated by the Level 1 at-power PSA results in OPG Report [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014] which show that event sequences involving the failure to shut down are a very small contributor to the severe Core Damage Frequency.

In Units 5-8, the independent Shutdown Systems are SDS1 (shutoff rods) and SDS2 (poison injection into the Moderator). Both Shutdown Systems are capable of shutting the reactor down fast enough for all AOOs and DBAs such that specified limits are not exceeded. There is no post-trip recriticality following accidents, including the limiting postulated event of an in-core LOCA if the ECI System operates as designed. For SDS1, operator action can be credited 15 minutes after an in-core LOCA to augment the depth of shutdown, for example to ensure that re-criticality does not occur in the unlikely event that ECI does not operate. For SDS2, the shutdown depth is sufficient to keep the reactor shut down indefinitely for even the most reactive conditions of the core.

For Units 1,4, on SDSA and for Units 5-8 on SDS1, each trip channel can be connected to a channel of start-up instrumentation which measures neutron flux at very low power levels. The Pickering NGS startup instrumentation is described in the review of Safety Principle D-205, Startup, Shutdown, and Low Power Operation.

The automatic Shutdown Systems are also described in Safety Principle D-192, Protection Against Power Transient Accidents.

In conclusion, the automatic Shutdown Systems in Pickering NGS are independent of the Reactor Control Systems and are available during the approach to critical, when the reactor is critical at low power, and when the reactor is operating at power.

D-207 – Emergency Heat Removal

Principle: Provision is made for alternative means to restore and maintain fuel cooling under accident conditions, even if normal heat removal fails or the integrity of the primary cooling system boundary is lost.

The ECI System is designed to refill the Heat Transport System following a LOCA and to provide coolant makeup and the heat sink in the long term via the ECI heat exchangers. In both Units 1,4 and Units 5-8, the ECI System has two principal operating modes:

(a) The high pressure injection mode is used immediately after the accident up to the time the ECI water storage tank level is low. Water flows from the ECI storage tank through the high pressure injection pumps to the ECI header. It then enters the reactor headers via the injection lines and the shutdown cooling loops and eventually discharges from the break and flows to the fuelling machine service room sumps. If all high pressure injection pumps are unavailable, the storage tank will feed the injection header by gravity.

(b) The long term recovery mode is used after the initial injection mode for as long as recovery is required. During ECI recovery, water from the fueling machine service room(s) sump(s) (recovery sump in Units 5-8) is used to refill the Heat Transport System using the Moderator pumps for Units 1,4 and ECI Recovery Pumps for Units 5-8.

For events involving a loss of Steam Generator inventory (steam line break or loss of feedwater), qualified backup boiler water supplies are available to remove the decay heat generated in the Fuel. In Units 1,4, the Boiler Emergency Cooling System is designed to provide a short term heat sink for reactor decay heat removal via Steam Generators in order to allow the operator sufficient time to bring in a long term heat sink for accident situations initiated by or leading to failure of the normal feedwater supply. The Boiler Emergency Cooling System is a non-nuclear system qualified to Design Basis Earthquake Category B. The Boiler Emergency Cooling System injection valves will open automatically. The water from the system's water storage tanks is supplied to the boilers via the reheater drains return piping. Normally the water level in TK1/TK2 is maintained at approximately 2.2 m, which should provide sufficient water inventory for at least 15 minutes of heat sink [Section 5.1.8 of NA44-SR-01320-00001-R016, *Pickering A Safety Report*, July 20, 2017].

The Emergency Boiler Water Supply System is designed to provide a long-term supply of emergency water to the boilers of Units 1,4 following a postulated main steamline failure within the Units 1,4 powerhouse. It is also capable of providing water to the boilers for a total loss of feedwater event, following operator action to depressurize the boilers. A steam line failure could result in a loss of service water via failures of non-environmentally qualified Class III and IV electrical distribution equipment exposed to the resultant powerhouse environment. The emergency water is supplied from the discharge headers of the Units 6 and 7 High Pressure Service Water System.

In Units 5-8, the Boiler Emergency Cooling System provides water for reactor decay heat removal by the boilers for accident situations initiated by or leading to failure of the normal feedwater supply. The Boiler Emergency Cooling System injection valves are signaled to open automatically and injection will continue until the inventory stored in the water tanks has been depleted. Boiler Emergency Cooling System operation ensures that at least an additional 15 minutes of heat sink capability is available. In addition, the Emergency Water System is a seismically qualified system for supplying long-term emergency makeup to the boilers, Heat Transport System, ECI recovery heat exchangers, Containment air coolers and the Calandria. The main Emergency Water System pumps are supplied by lake water. The water is distributed through an independent, seismically qualified piping system. The Emergency Water System is manually operated and is common to Units 5, 6, 7 and 8. Each unit has a manually operated valve station located next to the Unit Emergency Control Centre. The Emergency Water System is powered from the seismically qualified Emergency Power System.

In Pickering NGS Units 1,4 and 5-8, Emergency Mitigating Equipment has been provided for an additional makeup water supply. Portable diesel-powered pumps can be deployed to provide make-up to the secondary side of the boilers, to the Heat Transport System and to the Moderator.

In summary, both Units 1,4 and Units 5-8 are equipped with systems that are designed to effectively remove heat from the Fuel and transfer it to the ultimate heat sink under accident conditions. The ECI System is capable of restoring and maintaining fuel cooling following a LOCA.

D-217 – Confinement of Radioactive Material

Principle: The plant is designed to be capable of retaining the bulk of the radioactive material that might be released from fuel, for the entire range of accidents considered in the design.

The Containment System is basically an envelope around the nuclear components of the reactor Primary Heat Transport System with provision for controlling the pressure within the envelope. The envelope is designed to limit any release of radioactivity to the environment which might result from a process or system failure. Because of the large amounts of energy stored in the reactor coolant, an energy absorbing system is provided which allows the Containment structure to withstand the initial pressure rise resulting from escaping fluid flashing to steam.

The principle of Negative Pressure Containment is employed in the Pickering NGS units. A Vacuum Building, maintained at a very low subatmospheric pressure, is linked to the Reactor Buildings by a pressure relief system. This arrangement ensures that the pressure within the Containment boundary will be brought below the surrounding atmospheric pressure within a short time following a pressure rise within a Reactor Building. Long-term control of Containment pressure is accomplished through controlled venting via the Filtered Air Discharge System.

The principal components of the Containment envelope are the Reactor Buildings, the Pressure Relief Duct, the vacuum ducts, the Pressure Relief Valves and the Vacuum Building. The Vacuum Building contains a water spray system consisting of an elevated water storage tank and spray headers designed to provide a dousing spray of water through the main chamber of the Vacuum Building to cool the air and condense any steam present. A Pressure Relief Duct with pressure relief valves interconnects all the Reactor Buildings and the Vacuum Building via the vacuum ducts. Pressure relief panels on Units 1 to 8 are provided to allow for flow of air and steam from individual Reactor Buildings to the Pressure Relief Duct. Pressure relief valves, located in the Pressure Relief Duct, normally isolate the duct from the Vacuum Building and relieve to the Vacuum Building via vacuum ducts when activated by high pressure.

The Vacuum Building, the pressure duct and valves are common to Units 1,4 and Units 5-8, with the Pressure Relief Duct interconnecting all eight Reactor Buildings. Isolation of Containment is initiated automatically if the differential pressure between any Reactor Building and the reactor auxiliary bay reaches the isolation setpoint, or if high activity is detected in a Reactor Building ventilation system exhaust, since these conditions indicate possibility of a radioactive release inside that Reactor Building.

The Emergency Water Storage Tank provides water for the dousing spray in the Vacuum Building, cooling to the bleed cooler and backup fire water to Units 1, 2, 3 and 4.

The structural integrity of the reactor buildings and Pressure Relief Duct is verified by operational tests in which an internal pressure is applied. The Containment operational leakage rate target is based on 1 per cent of the contained air mass per hour at an internal pressure equal to the design value of 41.4 kPa(g) (6.0 psig).

The purpose of the Filtered Air Discharge System is to maintain Containment sufficiently sub-atmospheric following an accident and to provide a filtered and monitored pathway to the environment. The system serves both Units 1,4 and Units 5-8. Using the Filtered Air Discharge System, Containment can be maintained at an adequate negative pressure with respect to the atmosphere after depletion of the vacuum in the Vacuum Building.

The purpose of the post-LOCA Hydrogen Ignition System is to safely combine any hydrogen (or deuterium) gases generated in Containment following accidents. The system is capable of addressing very low concentrations of hydrogen in air/steam mixtures, thus preventing the occurrence of high concentrations of hydrogen in Containment. In addition, Passive Auto-catalytic Recombiners have been installed to control Containment hydrogen levels, providing a backup to the Hydrogen Ignition System.

The effectiveness of the Containment System in limiting the release of radioactivity following an accident (single process failure or dual failure of the ECI System) such that the applicable single and dual failure dose limits are met is demonstrated by the analyses documented in Part 3 of the Pickering NGS Safety Reports.

In conclusion, the Pickering NGS Containment System is designed to retain the radioactive material that might be released from the Fuel during an accident, and Containment effectiveness is demonstrated by safety analyses showing that public dose meets the applicable regulatory limits for the full range of accidents considered in the design.

D-221 – Protection of Confinement Structure

Principle: If specific and inherent features of a nuclear power plant would not prevent detrimental effects on the confinement structure in a severe accident, special protection against the effects of such accidents is provided, to the extent needed to meet the general safety objective.

Specific features of the Pickering NGS design that contribute significantly to preventing Containment damage in a severe accident include:

- The very low frequency of uncontrolled reactivity events due to the highly reliable fast shutdown capability.
- The capability of the passive Moderator heat sink together with the Moderator Cooling System to prevent severe core damage.

The possibility that hydrogen generated during certain accidents could potentially lead to a challenge to Containment integrity was recognized in the CANDU industry well before the Three Mile Island accident. There are two systems for hydrogen control in Pickering NGS:

- Hydrogen Ignition System
- Passive Auto-catalytic Recombiners

The Hydrogen Ignition System in Pickering NGS is designed to safely combine any hydrogen (or deuterium) gases generated in Containment following accidents. Passive Auto-catalytic Recombiners have also been installed to control Containment hydrogen levels, providing a backup to the Hydrogen Ignition System.

Four coolers are provided for each of the two fuelling machine vaults. The cooling water flow through the coolers is increased automatically on detection of high ambient pressure. The licensing requirement is to have at least one fan available per vault to ensure adequate mixing of any hydrogen (or deuterium) gases generated within Containment following an accident, thereby avoiding the buildup of potentially high concentration pockets of gases.

Emergency Mitigating Equipment for design extension conditions has been installed as part of the Fukushima Action Plan, as described in Sections 18.2.2.1 and 18.2.2.2.

As is described in the review of Safety Principle AM-326, Engineered Features for Accident Management, implementation of Phase 2 Emergency Mitigating Equipment is in progress and will provide additional enhancements for the control of Containment pressure following BDBAs (see GI-40-RS1 in Appendix F).

The review of defence-in-depth relating to confinement of radioactive material for accidents within the design basis is covered in Safety Principle D-217, Confinement of Radioactive Material.

To summarize, provisions to minimize the severity of the challenge to Containment integrity resulting from a severe accident have been deployed in Pickering NGS. The Pickering Large Release Frequency Safety Goal is met as is discussed in Safety Principle AM-326, Engineered Features for Accident Management.

D-233 – Station Blackout

Principle: Nuclear plants are so designed that the simultaneous loss of onsite and offsite AC electrical power (a station blackout) will not soon lead to fuel damage. The use of ‘simultaneous’ is not intended to imply that the loss of onsite and offsite power necessarily occurs at the same time.

Features of the Pickering NGS contribute to significant delays in Fuel damage following a station blackout, without crediting operator action. Following a station blackout, a number of reactor trip signals would be generated within seconds, resulting in an immediate reduction of reactor power to decay power level. With forced cooling unavailable, the safety relief valves would open to discharge steam from the boilers and act as the heat sink for the reactor. Heat transfer from the core to the boilers occurs by buoyancy-driven flow. The boilers are designed with sufficient inventory to provide fuel cooling and prevent fuel overheating for a minimum of 15 minutes at decay power levels.

In reality, significant fuel overheating would be delayed well beyond 15 minutes due to the large inventory of water in the boilers. It has been estimated that the secondary side inventory would provide a minimum of 1 hour of cooling [N-CORR-03611-0348939-LOF, *Fukushima – Daiichi Follow – up: Summary of Timing Requirements for Maintaining and/or Restoring Fuel Cooling after Total Loss of Heat Sink Events*, April 6, 2012]. In addition, gravity feed from the Boiler Emergency Cooling System tanks (see Safety Principle D-207, Emergency Heat Removal) is estimated to provide an additional 2.5 hours of cooling. Finally, gravity feed from the elevated deaerator storage tank would provide an additional 5.5 hours of cooling. Therefore, at least

9 hours are available before the need for operator action to connect temporary on-site services (e.g., Emergency Mitigating Equipment). In the absence of such operator action, subsequent pressurization of the Heat Transport System would result in discharge of steam through the liquid relief valves. As Fuel Channels void and heat up, heat begins to be transferred to the Moderator. Pressure tube overheating at high Heat Transport System pressure eventually results in failure of one or a few Fuel Channels, which depressurizes the Heat Transport System. If fuel cooing is not restored, continued fuel heatup at low Heat Transport System pressure will result in pressure tubes sagging into contact with their Calandria tube, creating a path for heat removal to the Moderator for Fuel Channels below the Moderator level. The Moderator continues to remove decay heat and will heat up and boil if Moderator cooling is not provided. Eventually, after the top few rows of channels are exposed to steam cooling in the Calandria, failure of these channels will commence. However, this is delayed for several hours after the deaerator storage tank becomes drained.

As summarized in the Risk Assessment Summary Report [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014] station blackout is included in the events covered by the Level 2 PSA performed for Pickering NGS. In Units 5-8, a main steam line break, combined with failures causing station blackout, leading to a loss of heat sink and failure of ECI and Moderator cooling at four units simultaneously is selected as one of the representative accident sequences. Similarly, in Units 1,4, a total loss of heat sinks in all six operating Pickering NGS units is selected as a representative accident sequence.

Emergency Mitigating Equipment provided as part of the implementation of lessons learned from the 2011 Fukushima accident can be deployed to prevent significant Fuel damage in the longer term (> 8 hours) following a station blackout.

In conclusion, Fuel damage following a postulated station blackout is delayed for several hours in the Pickering NGS design, due to the large volume of coolant available for heat removal. In addition, deployment of Emergency Mitigating Equipment will significantly extend the time to Fuel damage or prevent it altogether.

D.8. Safety Principles Related to Levels 4, 5

The following safety principles are related to defence-in-depth levels 4, 5:

- EP-333 – Emergency Plans
- EP-336 – Emergency Response Facilities

As demonstrated below, Pickering NGS design and operation are aligned with all safety principles related to Levels 4, 5.

EP-333 – Emergency Plans

Principle: Emergency plans are prepared before the startup of the plant, and are exercised periodically to ensure that protection measures can be implemented in the event of an accident which results in, or has the potential for, significant releases of radioactive materials within and beyond the site boundary. Emergency planning zones defined around the plant allow for the use of a graded response.

OPG Program [N-PROG-RA-0001-R015, *Consolidated Nuclear Emergency Plan*, December 22, 2016] provides a written basis to document concepts, roles and resources required by OPG Nuclear to implement and maintain its emergency response capability to protect the public, employees and the environment in the event of a nuclear emergency. N-PROG-RA-0001-R015 defines a nuclear emergency as an emergency which poses an actual or potential hazard to public health and property or the environment from ionizing radiation, whose source is a major nuclear installation.

The emergency response capability established in accordance with N-PROG-RA-0001-R015 must be sufficiently flexible to be used for a broad range of events and disasters both within and beyond the design basis. That is, the full range of accidents and radiation emergencies spans a wide range of events from an impairment of a plant system to the occurrence of a BDBA that progresses into a severe accident.

The basis for emergency planning is described in Section 1.1 of the N-PROG-RA-0001-R015. Design basis documents for both on-site and off-site planning are listed in Section 4.2.2 of N-PROG-RA-0001-R015; this list represents the primary source from which the Emergency Plan is developed. Two of the documents listed in this section are the Pickering NGS Units 1-4 and Pickering NGS Units 5-8 Safety Reports, which identify and study the full range of accidents and radiation emergencies that are a part of the station design basis. N-PROG-RA-0001-R015 also recognizes the need to address BDBAs, including design extension conditions and severe accidents. Requirements for OPG's approach to BDBA management are documented in OPG Standard [N-STD-MP-0019-R002, *Beyond Design Basis Accident Management*, August 19, 2016], with BDBA strategies implemented through operating procedures, Emergency Mitigating Equipment Guidelines and Severe Accident Management Guidelines.

Elements and procedures include:

- Review issues that could impact emergency response, including local development which may modify/increase risks.
- The OPEX process monitors events around the world to determine if there is any unforeseen event that may have applicability to Pickering NGS. If an event is deemed to be applicable, the emergency response process is reviewed to ensure the event can be adequately dealt with.

OPG Procedure [N-PROC-RA-0040-R006, *Maintenance and Testing of Emergency Preparedness Facilities and Equipment*, April 30, 2015] defines the process used to monitor, periodically test and maintain the emergency response facility and equipment to ensure operability 24 hours a day, 7 days a week. This includes testing and facility walk-through frequencies and covers the different types of equipment, such as faxes, computers, radiation instruments, communication, meteorological and data transmitting equipment [N-PROC-RA-0133-R000, *Management of Equipment Important to Emergency Response*, December 18, 2014].

As noted in Section 1.3.4 of the Consolidated Nuclear Emergency Plan, the Provincial Nuclear Emergency Response Plan requires Pickering NGS to procure adequate quantities of stable iodine tablets for their Primary Zone population. Designated Primary Zone municipalities are also required to establish and maintain a public alerting system in accordance with the Provincial Nuclear Emergency Response Plan. In consultation with the designated municipalities, the OPG Emergency Preparedness Department procures stable iodine tablets and maintains them within expiry dates. Iodine tablets were pre-distributed to the Primary Zone population for Pickering NGS in 2015. OPG also supports the province and municipalities that provide coordinated emergency communications under the jurisdiction of the Provincial Nuclear Emergency Response Plan. Per Section 1.3.5 of the Consolidated Nuclear Emergency Plan, OPG provides resources and assistance to the designated Primary Zone municipalities to enable them to establish and maintain a public alerting system as required by the Provincial Nuclear Emergency Response Plan.

The adequacy of the response and mitigation strategies that have been developed is demonstrated primarily through drills and exercises. The Emergency Preparedness Department assesses the Emergency Response Organization performance to the established objectives identified in OPG Instruction [N-INS-03490-10002-R005, *Conduct of Emergency Preparedness Drills and Exercises*, December 31, 2014] and reviews all drill and exercise related corrective actions to monitor status and ensure completeness. Integrated and partial emergency exercises have been conducted at Pickering NGS to check satisfactory function of the emergency organization and its equipment.

It is concluded that emergency plans have been prepared under the Consolidated Nuclear Emergency Plan, and emergency preparedness drills are mandated and carried out for Pickering NGS. The emergency plans provide for enhanced response in the Primary Zone.

EP-336 – Emergency Response Facilities

Principle: A permanently equipped emergency centre is available off the site for emergency response. On the site, a similar centre is provided for directing emergency activities within the plant and communicating with the off-site emergency.

In the event of an emergency, there are permanent on-site and off-site facilities appropriately equipped for effective emergency response. During the initial emergency phase, Main Control Room staff perform the assessment of plant status. Where possible, the Main Control Room staff also identify damage to plant equipment. Appropriate plant procedures are used and Main Control Room staff initiate an immediate operations response to strive towards taking the plant to a safe and stable configuration.

The Main Control Room team utilizes resources of the on-site Emergency Operations Centre to mobilize and deploy the necessary emergency teams. The Emergency Operations Centre personnel may, if necessary, mobilize, brief and deploy Emergency Response Teams to address specific emergencies, such as a fire, medical emergency, or a search and rescue operation. Appropriate off-site support groups (i.e., non-OPG resources) such as fire and/or ambulance may be activated to respond to the site. In addition, the Emergency Operations Centre personnel may mobilize and deploy both in-plant and off-site radiation survey teams who provide additional data to assess the plant status. If the Main Control Room emergency mitigation strategy requires repair of damaged equipment, then the Emergency Operations Centre personnel assemble, brief and deploy the appropriate emergency repair teams. Main Control Room staff seek, as appropriate, consultative, technical and resource assistance from the Site Management Centre who in turn seek, as appropriate, assistance from the Corporate Emergency Operations Facility.

A permanently equipped Site Management Centre is maintained for directing emergency response. The Corporate Emergency Operations Facility, located in Whitby, is also permanently equipped to support and direct emergency response. The response is managed as detailed in [N-PROG-RA-0001 R015, *Consolidated Nuclear Emergency Plan*, December 22, 2016].

The Provincial Emergency Operations Centre, located at the Ministry of Community Safety and Correctional Services in Toronto, is the provincial facility and organization that directs off-site emergency response operations. OPG provides call-in staff to fill an official liaison officer position in the Provincial Emergency Operations Centre Operations Section, and provides and maintains software codes for dose projection, dedicated telecommunications links, and training and drills as requested to support the Provincial Emergency Operations Centre. During the response stage, site shift and management staff shall make emergency notification to the Provincial Emergency Operations Centre as appropriate. Technical data and situation updates, including off-site survey data, are provided to the Provincial Emergency Operations Centre from the incident site.

The Durham Regional Emergency Operations Centre is comprised of elected officials, regional department staff (e.g., roads and works, emergency planning, social services), school board staff, police, fire and medical representatives. The primary responsibility of this organization is to implement the public protective action directives in the locally affected area to protect the public. Only the Provincial Emergency Operations Centre shall provide direction and information on off-site response to the Regional Emergency Operations Centre. In the event of an emergency, OPG will provide a local site representative to fulfill the OPG liaison officer position at the Regional Emergency Operations Centre. The liaison officer will provide coordination with the site for resources and off-site response activities in the local area. The liaison officer will also provide radiation level interpretation and technical background information to the regional staff. Official emergency communication with the Regional Emergency Operations Centre is through the liaison officer and the Site Management Centre.

Additional off-site emergency response facilities include:

- Durham Region Reception Centres and Emergency Worker Centres. Reception Centres are established to provide, among other functions, a Monitoring and Decontamination

Unit for evacuees. These centres are under the control and direction of the Regional Emergency Operations Centre. OPG Nuclear site organization and call-in personnel staff and equip the Monitoring and Decontamination Unit function of these centres. Monitoring and Decontamination Unit staff are trained to carry out radiation monitoring and decontamination. OPG Monitoring and Decontamination Unit supervisors maintain communication with the Site Management Centre to keep the Emergency Response Organization apprised of the Monitoring and Decontamination Unit status and any need for further resources. Emergency Worker Centres are established during nuclear emergencies to monitor and control radiation exposure of external emergency workers who may be required to enter areas affected by radiation. Similar to Reception Centres, Emergency Worker Centres are under the authority of the Regional Emergency Operations Centre. Emergency Worker Centres are staffed by OPG call-in personnel with equivalent qualifications as Reception Centre Monitoring and Decontamination Unit staff. Communication is regularly maintained between the Emergency Worker Centre OPG supervisors and the Site Management Centre and Regional Emergency Operations Centre.

- City of Toronto, Municipal Emergency Operations Centre. A Municipal Emergency Operations Centre is equivalent to a Regional Emergency Operations Centre with regards to its role in the emergency response. OPG provides the same level of support to the City of Toronto Municipal Emergency Operations Centre as it does to the Durham Regional Emergency Operations Centre.
- Reception Centres and Emergency Worker Centres associated with the City of Toronto have the same functionality as corresponding centres for the Durham Region. OPG provides the same level of support to the City of Toronto Reception Centres and Emergency Worker Centres as it does for corresponding centres in the Durham Region.

It is concluded that suitably equipped on-site and off-site emergency centres are available to carry out emergency response activities.

D.9. Safety Principles Related to Level 1

The following safety principles are related to defence-in-depth Level 1:

- S-136 – External Factors Affecting the Plant
- D-188 – Radiation Protection in Design
- O-272 – Conduct of Operations
- O-288 – Normal Operating Procedures

As demonstrated below, Pickering NGS design and operation are aligned with all safety principles related to Level 1.

S-136 – External Factors Affecting the Plant

Principle: The choice of site takes into account the results of investigations of local factors that could adversely affect the safety of the plant.

The site characteristics are described in the Pickering NGS Safety Reports Part 1. Descriptions and data are provided for:

- Geography and demography (site location, site description, access, population)
- Land use (agriculture, industry, fishing, recreation, transportation)
- Geology (regional geology, site geology)
- Seismology (regional seismicity, seismic ground motion, seismic design)
- Hydrology (water treatment plants, lake currents, water levels, water temperatures, thermal plumes, ice, aquatic weeds, ground water)
- Meteorology (temperature, precipitation, wind, atmospheric stability).

A screened list of external hazards for inclusion in the Level 1/Level 2 PSA for Units 1,4 and Units 5-8 was completed as part of the Hazard Screening Analysis for the Pickering PSA update [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014]. This list is compliant with both CNSC Regulatory Standard S-294 and international practice (such as US Nuclear Regulatory Commission NUREG/CR-2300). The External Hazards Screenings contained in these reports rely on the concept of Review Level Conditions for external hazards against which the station's current design is reviewed. Originally defined and analyzed for various external events in the hazard screening analyses, the Review Level Conditions were further analyzed and refined for tornado, seismic and external flooding hazards. Any changes in site characteristics with an impact on nuclear safety are captured in Part 1 of the Safety Reports during the Safety Report updates. The impacts of changes in the site characteristics are then captured in the development of models and methodology for internal and external hazard analyses.

To summarize, the local characteristics were considered in the original design of Pickering NGS, a review of potential external hazards has recently been completed and appropriate hazard assessments have been conducted.

D-188 – Radiation Protection in Design

Principle: At the design stage, radiation protection features are incorporated to protect plant personnel from radiation exposure and to keep emissions of radioactive effluents within prescribed limits.

The initial design of Pickering NGS was created to ensure that the layout and operation of facility SSCs and processes were consistent with the established radiation protection guidelines and contribute to maintaining occupational radiation exposures ALARA. During the initial design stage, emphasis was placed on the reduction of occupational radiation doses, which resulted in design improvements that allowed Pickering NGS and other early CANDU designs to have far fewer workers exposed to measurable radiation doses than most other utilities, despite increased staffing needs associated with online fueling, as documented in OPG Report [N-REP-N7250014, *Excellence Through Radiation Protection Practices in Ontario Hydro CANDU-PHW Nuclear Electric Generating Stations*, September 1987].

As indicated in Section 12 of the Pickering 1,4 and 5-8 Safety Reports [NA44-SR-01320-00001-R015, *Pickering A Safety Report*, July 24, 2012, NK30-SR-01320-00002-R004, *Pickering B Safety Report – Part 2*, October 10, 2012] and N-PROG-RA-0013-R010, *Radiation Protection*, February 21, 2017, specific design features at Pickering NGS to control radiation dose include the use of shielding, ventilation and emissions control, radiological zoning and the provision of area radiation monitoring equipment. The use of shielding and ventilation control reduces exposure to external radiation and airborne radioactive material, respectively. The use of emissions control reduces the doses to members of the public. The use of radiological zones limits the spread of contamination by requiring personnel and materials crossing zone boundaries to be monitored for radioactivity, depending on the direction of travel. The use of area radiation monitoring equipment warns personnel of any sudden or unexpected changes in radiological hazards.

N-PROG-RA-0013-R010, *Radiation Protection* further mandates that “when making engineering changes, engineers maintain or improve upon designs that reduce occupational exposures”. At Pickering NGS this process is implemented through OPG Standard [N-STD-RA-0018-R007, *Controlling Exposure As Low As Reasonably Achievable*, November 27, 2014].

At Pickering NGS, facilities are provided for safe temporary storage of liquid and solid wastes, as well as for safe handling of all radioactive gaseous, liquid and solid wastes. All equipment, tanks and facilities for handling liquid and solid wastes are flexible enough to cope with the anticipated increase in waste volume and activity during periods of major maintenance work or adverse reactor operation. Gaseous wastes are monitored, managed and filtered as appropriate to maintain operation within acceptable limits.

The Radioactive Liquid Waste Management System is common to Units 1,4 and Units 5-8. This system receives and selectively treats the waste streams directed to it by the normally inactive and normally active drainage systems, as described in the Safety Report, Part 2.

The system is designed such that on an annual basis the sum of the fractional contributions from all radionuclide groups from Units 1,4 and Units 5-8 will not exceed the station Action Levels. The Action Levels are set at 10% of the Derived Release Limit for a particular radionuclide/radionuclide group for both airborne and liquid emissions. Additionally, for liquid effluents, the derived liquid concentration is used to limit the concentration in the outfall.

Release of tritium from the station is kept within limits by containment of heavy water within the Heat Transport and Moderator Systems where the tritium is produced, by containment of heavy water vapour within the Reactor Building, and by recovery of any leakage from the heavy water circuits.

In conclusion, design features have been included in the Pickering NGS design for minimizing radiation exposure to the plant personnel and limiting releases of radioactivity to the environment.

O-272 – Conduct of Operations

Principle: Operation of the plant is conducted by authorized personnel, according to strict administrative controls and observing procedural discipline.

OPG has a well-defined organizational structure and strong lines of authority. OPG Program [N-PROG-OP-0001-R008, *Nuclear Operations*, December 4, 2015] establishes safe, uniform and efficient operating practices and processes within OPG Nuclear facilities.

The OPG Charter [N-CHAR-AS-0002-R019, *Nuclear Management System*, November 1, 2016] describes the OPG Nuclear Quality Program, while OPG Standard [N-STD-AS-0020-R014, *Nuclear Management Systems Organizations*, May 19, 2016] outlines its implementation. N-STD-AS-0020-R014 establishes the lines of authority and definition of duties. It provides a summary of the interfacing organizations that own programs supporting the Nuclear Management System. Operation and maintenance of the station as per regulatory requirements and Nuclear standards for public safety are directed by the Director, Operations and Maintenance, who also coordinates with the centre-led organizations (see Safety Principle O-265, Organization, Responsibilities and Staffing) to effectively use resources to achieve performance targets. The quality and quantity of services provided by these centre-led support organizations is monitored by the site Senior Vice President, who holds responsibility for establishing site requirements and priorities. The position specific role document, N-MAN-08131 series, describes the duties, authorities and accountabilities of the positions described in the standard.

Nuclear safety oversight is established to ensure that the requirements of OPG Policy [N-POL-0001-R003, *Nuclear Safety Policy*, April 7, 2014] and N-CHAR-AS-0002-R014 are implemented throughout OPG Nuclear. The framework, accountabilities for nuclear safety oversight, as well as the external and internal processes used for oversight and assessment of nuclear safety are summarized in OPG Standard [N-STD-AS-0023-R008, *Nuclear Safety Oversight*, September 15, 2015].

Significant operational decision making is conducted as per [N-STD-OP-0036 R009, *Operational Decision Making*, April 17, 2015].

[N-GUID-03611-10005-R004, *Integrated Risk Management Guidelines*, May 4, 2015] establishes the administrative controls, responsibilities, duties for direction, control, conduct and oversight of risk-significant activities (Nuclear Safety, Conventional Safety, Environmental, Generation and Radiological), infrequently performed tests or evolutions and infrequent maintenance activities at OPG Nuclear.

Pickering NGS processes for managing, implementing and adhering to operating and working procedures and for maintaining compliance with operational limits and conditions (see Safety

Principle O-284, Operational Limits and Conditions) and regulatory requirements are effective at ensuring plant safety. Compliance with procedural adherence requirements is evaluated in part through the use of self-assessment and benchmarking activities. OPG Procedure [N-PROC-RA-0097-R009, *Self – Assessment and Benchmarking*, May 1, 2017] defines the elements required to plan, execute, report and monitor self-assessments and benchmarking activities for the functional and line organizations of OPG Nuclear. Self-assessment and benchmarking are performance improvement tools that provide a structured method to compare performance with management expectations, industry standards of excellence and regulatory requirements to identify areas needing improvement. Self-assessments include evaluations of business programs, processes and performance.

Issues with regard to specific procedures are reviewed under their respective applicable safety principles.

To summarize, administrative controls are in place to ensure that plant operations are conducted by authorized personnel, according to strict administrative controls and observing procedural discipline.

O-288 – Normal Operating Procedures

In this section, both O-288 and O-290 are addressed, as they constitute a continuum of plant operational states.

O-288 – Normal Operating Procedures
Principle: Normal plant operation is controlled by detailed, validated and formally approved procedures.

O-290 – Emergency Operating Procedures
Principle: Emergency operating procedures are established, documented and approved to provide a basis for suitable operator response to abnormal events.

OPG Program [N-PROG-OP-0001-R008, *Nuclear Operations*, December 4, 2015] establishes safe, uniform and efficient operating practices and processes within OPG Nuclear facilities that provide nuclear professionals the ability to ensure facilities are operated in such a manner that Power Reactor Operating Licences, Operating Policies and Principles and other applicable regulations and standards are followed.

There are operating procedures that apply comprehensively to normal, abnormal and emergency conditions (including AOOs, DBAs, post-accident conditions and design extension conditions).

Pickering NGS operations staff normally operate the plant through the use of approved Operating Manuals, Operating Procedures, Alarm Response Manuals and Safety-Related System Tests. Operating Manuals are produced for individual plant systems and provide instructions on equipment operation and controls.

Operations staff will initially attempt to respond to an abnormal condition via the system-based Operating Manuals or Alarm Response Manuals, as applicable. Specifically, the following sections of Operating Manuals are applicable to the initial response to abnormal conditions:

- Section 5.0, Non-Standard Operating Conditions
- Section 6.0, Actions Following Trips and Alarms
- Section 8.0, Auxiliary Services Failures

If it is not possible to address the abnormal condition through the system Operating Manuals and/or Alarm Response Manuals, staff will respond per the applicable Abnormal Incident Manual.

The Abnormal Incident Manuals are used to respond to both abnormal and emergency conditions. Of particular relevance to abnormal conditions are Sections 3 and 4 of the Abnormal Incident Manuals, which address faults (commonly referred to as impairments) that may reduce the effectiveness of safety systems or other Safety-Related Systems.

Upon confirmation or diagnosis of emergency conditions, including DBAs, staff respond per the event-based Abnormal Incident Manuals and continue to monitor conditions as per the Critical Safety Parameter Abnormal Incident Manual. Continued use of the Critical Safety Parameter Abnormal Incident Manual ensures that operating staff perform independent checks of key parameters indicative of overall unit health, to determine if any further actions are required to complement the event-based Abnormal Incident Manuals that are in use. Once Abnormal Incident Manual actions to achieve these objectives have been successfully implemented, there is subsequent direction on longer-term actions that need to be completed in order to effectively manage post-accident conditions resulting from the event.

BDBA management strategies are described in OPG Standard [N-STD-MP-0019-R002, *Beyond Design Basis Accident Management*, August 19, 2016] and implemented through operating procedures, Emergency Mitigating Equipment Guidelines and Severe Accident Management Guidelines. Emergency Mitigating Equipment Guidelines and Severe Accident Management Guidelines are used to respond to all BDBAs, including design extension conditions and severe accidents.

Emergency Mitigating Equipment Guidelines are entered when entry conditions specified in the event-based Abnormal Incident Manuals are met. Emergency Mitigating Equipment Guidelines have a primary focus on fuel cooling and are used to mitigate accident progression when design basis equipment is unable to provide adequate core cooling. The intent of Emergency Mitigating Equipment Guideline use is to prevent a BDBA sequence from progressing to a severe accident.

Severe Accident Management Guidelines is a set of written guidance to implement strategies should a BDBA progress to a severe accident. Severe Accident Management Guidelines are entered based on entry conditions in the Emergency Mitigating Equipment Guidelines, Critical Safety Parameter or event-based Abnormal Incident Manuals being met. Entry to Severe Accident Management Guidelines implies that adequate fuel cooling has been lost and severe core damage is either imminent or has occurred. The goals of Severe Accident Management Guidelines are to terminate progression of core damage, if possible, by restoring cooling, and to maintain Containment integrity and minimize radioactive releases. The Severe Accident Management Guidelines allow flexibility in application and the Severe Accident Management Guidelines document set is referred to as “guidance”. In addition, the Severe Accident Management Guidelines aid in identifying longer-term actions that will be required to address post-accident conditions once the station has been returned to a controlled, stable state.

It is concluded that the normal and emergency operating procedures for Pickering NGS are structured and comprehensive, and provide a sound basis for operation of the plant and for operator response to abnormal occurrences.

D.10. Safety Principles Related to Level 3

The following safety principles are related to defence-in-depth Level 3:

- D-168 – Automatic Safety Systems
- D-174 – Reliability Targets
- D-177 – Dependent Failures
- D-182 – Equipment Qualification
- D-237 – Control of Accidents Within the Design Basis

As demonstrated below, Pickering NGS design and operation are aligned with all safety principles related to Level 3.

D-168 – Automatic Safety Systems

Principle: Automatic systems are provided that would safely shut down the reactor, maintain it in a shut down and cooled state, and limit any release of fission products that might possibly ensue, if operating conditions were to exceed predetermined set points.

Descriptions and review of the automatic Safety Systems are provided under the following safety principles:

- D-200 – Automatic Shutdown Systems (for the Shutdown Systems)
- D-207 – Emergency Heat Removal (for the ECI System)
- D-217 – Confinement of Radioactive Material (for the Containment System)

The effectiveness of these systems in performing their safety functions and ensuring that the applicable acceptance criteria are met during a transient or accident is substantiated by safety analyses documented in Part 3 of the Pickering NGS Safety Reports.

D-174 – Reliability Targets

Principle: Reliability targets are assigned to safety systems or functions. The targets are established on the basis of the safety objectives and are consistent with the roles of the systems or functions in different accident sequences. Provision is made for testing and inspection of components and systems for which reliability targets have been set.

Reliability targets and the need for inspection and testing to support them were identified early in the development of the CANDU design. In 1972, the unavailability criteria were made more stringent with the unavailability requirement becoming 1 x 10^{-3} for each safety system, for reactors built after Pickering NGS Units 1-4. The reliability of the Shutdown System in Units 1-4 was improved for units being returned to service (Unit 1 and Unit 4). A second separate system was not feasible because of limited penetrations into the Calandria and high radiation fields in some areas. Instead, an enhancement (SDSE) of the existing shutdown features was installed to provide a new separated and diverse set of triplicated trip sensors and trip logic. In addition, two more shutoff rods were added in Units 1,4 to bring the total to 23. This enhancement has increased shutdown reliability to provide additional assurance that any anticipated transient will be terminated with little or no consequence.

In 1995, the unavailability target for the Shutdown System in Pickering NGS Units 1,4 was changed from 3 x 10^{-3} years/year to 1 x 10^{-3} years/year. During the return to service activities the unavailability target for Units 1,4 was revised to 1 x 10^{-3} years/year for the Negative Pressure Containment System and 2 x 10^{-3} years/year for the ECI System.

In Units 5-8, each of the Special Safety Systems (SDS1, SDS2, ECI and Negative Pressure Containment) has a reliability target of 1 x 10^{-3} years/year.

The Special Safety Systems and standby safety support systems are tested on a regular basis to ensure they will be available to operate if called on. The systems are designed to facilitate testing of all components, either as a system or in a series of overlapping component tests. Test frequencies are established to ensure that the systems meet defined reliability requirements. By testing the components of these systems at known frequencies, the actual availability can be monitored and compared against the expectation. Unavailability and PSA models are used during the design of modifications to the plant to confirm that the systems meet their system reliability requirements. The models use component failure rates and test frequencies to arrive at predicted system unavailability. During operation, component fault data are collected, and predicted future unavailability is recalculated and reported to the CNSC on a yearly basis for Systems Important to Safety, using this actual component experience.

Standby safety support systems, such as the standby emergency generators, are also tested regularly so that the system reliability can be tracked.

The SDS1 and SDS2 tripping detectors and logic are tested at power without initiating the system since 2 out of 3 channels are required for initiation. Partial drop tests of the SDS1 shutoff rods are done regularly, and a full test of the system is done during unit shutdowns. Shutdown System reliability is monitored and reported regularly and has always been substantially better than the 10^{-3} years/year unavailability requirement.

Periodic testing of the ECI System components is done to demonstrate its availability. All necessary testing of ECI System valves can be conducted when the reactors are at power. Since the whole system cannot be tested without interfering with normal reactor operation, the design allows for a series of overlapping tests that cover all functions of the system. If the unit-specific portions of the ECI System are unavailable, there is a limited time to correct the problem before the reactor must be shut down. If the common portion of the ECI System is unavailable, there is again a limited time to correct the problem before the entire station must be shut down.

Periodic functional testing is done on all automatic Containment closures and on the pressure relief valves during operation. The present practice is to test the valves yearly (one valve per month). Visual inspection of the equipment air lock door and the emergency air lock door seals is done during operation. The leakage rates of air locks with both doors closed is checked periodically.

As required by CNSC Regulatory Document RD/GD-98, *Reliability Program*, OPG has developed lists of Systems Important to Safety for Pickering Units 1,4 and 5-8. The Systems Important to Safety, along with their unavailability targets are documented in OPG Report [P-REP-09051.1-00016-R000, *Pickering NGS – 2016 Annual Risk and Reliability Report*, March 31, 2017]. The Systems Important to Safety for Pickering NGS are:

- Shutdown Systems
- Emergency Coolant Injection System
- Negative Pressure Containment System
- Standby Class III Power System
- Auxiliary Boiler Feedwater System
- Standby Class III Service Water System
- Heat Transport Shutdown Cooling System
- Powerhouse Emergency Venting System
- Emergency Water System (Units 5-8) and Emergency Boiler Water System (Units 1,4)
- Class III Inter-Station Transfer Bus and Class III Motor Control Centres (Units 1,4)
- Emergency Power System and Class II Power (Units 5-8)
- Heat Transport D_2O Recovery System (Units 1,4)
- Heat Transport Pressure and Inventory Control System (Units 1,4)

It is concluded that suitable unavailability targets are established for the Special Safety Systems. Periodic testing of the system components verify the targets are met. The safety system unavailability is assessed annually in the Annual Reliability Report. Also, standby safety and support systems are tested regularly so that the system reliability can be tracked.

D-177 – Dependent Failures

Principle: Design provisions seek to prevent the loss of safety functions due to damage to several components, systems or structures resulting from a common cause.

The Pickering NGS Units 1,4 and 5-8 designs include protection against common cause events. The design includes provisions to prevent the loss of safety functions due to damage to several components, systems or structures resulting from a common cause. For Units 5-8, redundant equipment and circuits are separated and grouped (Group 1 and Group 2) to ensure the safety of the station following a common mode event such as a turbine missile. Each group is capable, independently of the other group, of safely shutting down the reactor, cooling the Fuel and providing the operator with indications of system conditions. Units 1,4 were not designed with Group 1 and Group 2 systems. However, systems have been either qualified or retrofitted to function as required for a given common mode event by ensuring effective separation and diversity. Specific common cause events are addressed in the design as follows:

Seismic Qualification

Seismic qualification of Units 5-8 was established during the design and construction phases. Nuclear Safety Design Guide [DG-30-68000-2 R01, Pickering G. S. 'B', *Engineering Design Guide, Seismic Qualification of Safety Related Systems*, December 3, 1979] establishes the basis of Seismic Qualification and identifies those systems that are required to be qualified to permit execution of the basic safety functions following the occurrence of a low probability severe earthquake at the station site. This Design Guide also describes the two seismic categories (Design Basis Earthquake and site design earthquake[35]) that define functional requirements during or following an earthquake, as well as the levels of seismic excitation that structures or equipment must withstand. Acceptable methods for demonstrating qualification are also listed. The requirements of the Nuclear Safety Design Guides were implemented in design output documents such as Design Manuals, System Design Requirements, Technical Specifications and Specification Data Sheets for equipment and System Flow Diagrams. The information related to the Pickering site seismic hazard has been included in the Pickering 5-8 PSA based Seismic Margin Assessment [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014].

For protection against seismic events, Pickering NGS Units 1,4 was constructed according to the National Building Code of Canada. The Units 1,4 SSCs required to perform functions during and following an earthquake were not originally required to be seismically qualified; however, a static load of 5% was specified by the National Building Code to address seismic events. Seismic Qualification for Units 1,4 has subsequently been established by analysis [NA44-REP-02004-0073-R000 Vol 1-7, *Seismic Assessment of Pickering A Nuclear Generating Station Summary Report*, February 25, 1998]. Although the Units 1,4 systems were not originally required or designed to be Seismically Qualified, the equipment was subsequently evaluated and a Safe Shutdown Equipment List has been defined by the 1998 Seismic Margin Assessment. The Seismic Equipment List identifies the SSCs required for the seismic success

[35] The site design earthquake is defined as an earthquake occurring within 24 hours after a LOCA.

path [NA44-REP-02004-00002-R001, *Pickering NGS A Seismic Success Path Addendum Including the Safe Shutdown Equipment List*, August 13, 2013]. A PSA based Seismic Margin Assessment was completed in 2013 [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014].

Tornado

A tornado was not considered a design basis event during the design of either Units 1,4 or Units 5-8 but was addressed as part of the building code. Tornado and hurricane winds were assessed in Hazard Screening Analyses that confirmed that the reactor's ability to control and contain will remain intact following a tornado. A detailed assessment of margin available in the structures of both Units 1,4 and Units 5-8 to cope with a probable maximum tornado event was therefore recommended by these reports.

Subsequently, high wind related hazards were included in the scope of both the Units 1,4 and Units 5-8 PSAs. The most current high wind PSA analyses for both stations are documented in [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014].

External Flooding

The overall flood protection system for the Pickering site consists of the shoreline breakwater works, catch basins and storm sewers. The ground surface elevation of the Pickering site exceeds the 1 in 200 year lake water level. In the event that overtopping of flood protection occurs due to a high-magnitude storm coupled with high Lake Ontario level, lake water will be collected in the catch basins, while the storm sewers will discharge this water either directly back to the lake or to the intake channel.

External Flooding was assessed as per the methodology [N-GUID-03611-10001 Vol 8 R004, *OPG Probabilistic Safety Assessment (PSA) Guide External Hazard Screening*, September 16, 2016]. The consequences of external flooding events were assessed in the Hazard Screening Analyses for both Units 1,4 and Units 5-8. The majority of identified flooding events are screened out of both Units 1,4 and Units 5-8 as a result of these assessments.

Missile Protection

As described above, grouping and separation of equipment is used to protect against the loss of safety functions resulting from missiles. The consequences of internally generated missiles have been assessed in Hazard Screening Analyses as per methodology [N-GUID-03611-10001 Vol 9 R002, *OPG Probabilistic Safety Assessment (PSA) Guide Internal Hazard Screening*, November 10, 2016]. Possible missiles originating from turbine disintegration, the failure of various valves and pumps and the explosion of acetylene bottles used for cutting and welding were assessed. The failure of turbines, pumps and valves were screened out due to low impact after considering the separation of independent systems and the inclusion of protective barriers in the Pickering NGS design, while missiles due to acetylene bottle explosions were screened out due to low frequency.

Protection Against Dynamic Effects Associated with the Rupture of Piping

Pipe ruptures in Pickering NGS have been assessed for their potential for consequential damage to other components which could jeopardize the safe shutdown and continued cooling of the reactor. Critical SSC pipework, particularly for the Primary Heat Transport, Shutdown System (SDS) and ECI Systems have been analysed for pipe whip potential at varying temperatures. As described in Part 2 of the Pickering NGS Units 5-8 Safety Report, earlier studies considered the effect of whipping pipes and jet effects. The layout was reviewed to ensure that loop-to-loop break propagation would not occur. This required the addition of pipe restraints on all the 350 mm (14 in.) primary heat transport pipes between the reactor outlet headers and the Steam Generators. In addition to the primary heat transport piping restraints, a pair of pipe restraints was added to each of the reactor headers to prevent propagation or worsening of consequences from certain postulated pipe breaks. Also, deflector plates have been installed to protect instrumentation and electrical cable runs that are required for safe shutdown and continued cooling of the reactor.

An assessment of the dynamic effects associated with the rupture of high-energy piping for Units 5-8 was completed in 2016 [P-REP-04960-00014 R01, *Pipe – Whip and Jet – Impingement Assessment of Piping Inside Reactor Building - Units 5-8*, May 26, 2016] and confirmed that the layout of the high-energy piping and Safety-Related Systems inside of the Reactor Buildings of Units 5-8 are in compliance with the practices, expectations and guidelines in modern standards. Furthermore it indicated that this finding can be used for the reclassification of CSI-IH6 in Units 5-8 from Category 3 to Category 2, such that appropriate measures are in place to maintain the safety margins for this hazard. A similar assessment for Units 1,4 is underway, and this is reflected in the planned resolution of GI-25, Category 3 CANDU Safety Issues.

In addition, Part 3 of the Pickering NGS Safety Reports address consequential damage resulting from rupture of a Fuel Channel. The assessments confirm that these hazards do not result in unacceptable consequences despite potential damage to in-core structures and Calandria tube collapse for neighbouring Fuel Channels, and partial impairment of the insertion of the shutoff rods.

Environmental Qualification of Safety-Related Equipment.

The Environmental Qualification (EQ) program [N-PROG-RA-0006 R008, *Environmental Qualification*, June 3, 2015] provides the documented assurance that essential Safety-Related Systems, components and structures are capable of performing their functions when subjected to the environmentally harsh conditions that could result from postulated DBAs (see Safety Principle D-182, Equipment Qualification).

As described above, the Pickering NGS design also includes additional provisions to prevent the loss of safety functions due to damage to several components, systems or structures resulting from a common cause. For example, the Inter-Station Transfer Bus and Emergency Boiler Water Supply systems have specifically been installed to mitigate high energy pipe failures in the powerhouse. Steam protected rooms and barriers have been installed to protect critical equipment and staff. For seismic events, systems including power (Class I/II/III), water and control have been hardened to provide assurance that they will remain operational. Specific considerations for the reactor Shutdown Systems include:

- In Units 5-8 the two Shutdown Systems, SDS1 and SDS2, are functionally and physically independent of each other and functionally independent of the Reactor Regulating System. In Units 1,4, the Shutdown System reliability has been improved by retrofitting a Shutdown System Enhancement (SDSE) that provides sensors and trip logic independent from those of the original Shutdown System (SDSA).
- In Units 5-8, independence is achieved by employing diverse shutdown principles, i.e., SDS1 uses solid shutoff rods (gravity driven with spring assistance), and SDS2 directly injects poison into the Moderator (pressurized injection). The systems, including ancillary equipment, are also physically separated. The shutoff rods are inserted vertically into the top of the reactor. The poison injection tubes are inserted horizontally into the side of the reactor.
- In Units 1,4, independence and separation is implemented for the sensors and trip logic, but SDSA and SDSE employ the same gravity-driven shutoff rods with spring assistance.
- The Moderator Dump System in Units 1,4 augments the shut-off rods. Automatic operation of the dump system occurs when reactor power has been measured as not decreasing fast enough, or not reaching a sufficiently low level, following operation of the Shutdown System.

To summarize, Pickering NGS design addresses dependent failures, using separation of redundant SSCs for responding to common mode events. Hazard assessments have been performed that confirm the capability of the design to perform the required safety functions following postulated common mode events.

D-182 – Equipment Qualification

Principle: Safety components and systems are chosen that are qualified for the environmental conditions that would prevail if they were required to function. The effects of ageing on normal and abnormal functioning are considered in design and qualification.

The Pickering NGS EQ program [N-PROG-RA-0006 R008, *Environmental Qualification*, June 3, 2015] establishes an integrated and comprehensive set of requirements that provide assurance that essential equipment can perform as required when exposed to harsh conditions during an accident, and that this capability is preserved over the life of the plant. Implementation of these program requirements provides the methodology, programmatic controls and interfaces for establishing and maintaining EQ of equipment and components.

The scope of the EQ program covers all components that are essential to provide a safety function consistent with the assumptions and requirements documented in the current accident analysis summarized in the Safety Reports. All single and dual failure accidents within the design basis are covered; these are termed DBAs for the purpose of the EQ program. For each accident defined, the EQ program ensures that a reliable and qualified line of defence is provided to achieve and maintain reactor shutdown, fuel heat removal, Containment and post-accident monitoring.

A suite of engineering programs and processes exists to ensure that EQ requirements are met and documented. Qualification is established through testing, analysis, OPEX, ongoing qualification or a combination of these methods. EQ Assessments identify equipment specific design, configuration, maintenance and procurement requirements necessary to establish and maintain the qualified status of equipment.

Environments where equipment and components are installed are monitored to ensure conditions used in EQ are valid. Surveillance is completed to ensure the installed configuration of electrical equipment conforms to EQ related design and configuration requirements. Periodic inspection and maintenance of EQ barriers are completed to ensure their integrity throughout the life of the plant.

The EQ process consists of the following general steps:

- Listing the DBAs and identifying those that result in post-accident harsh environments with the potential to cause common mode failures.
- Identifying in an EQ Design Guide the systems with EQ requirements due to their role in mitigating the harsh environment DBAs, based on compiling a list of structures, systems, equipment and components that are credited in the safety analysis.
- Defining, for each of the harsh environment DBAs, all rooms of the plant as either harsh or mild. For rooms that are classified as harsh, the environmental conditions are derived for the bounding accident.
- Preparing an EQ List Development Package that lists equipment by parent devices as extracted by the EQ Design Guide. Equipment interfaces, functional requirements and failure modes are established and equipment is classified as either fail-safe or requiring an EQ Assessment.
- Placing equipment that does not fail-safe and must operate in a harsh DBA environment on the EQ List. Equipment on the EQ List must be qualified and documented with an EQ List Development Package. An EQ Assessment document is produced to document the design basis assurance that demonstrates the equipment’s capability to perform its safety function, under harsh environment resulting from applicable DBAs.

Equipment identified in the EQ List must maintain its qualification status as prescribed in the EQ Assessment documents. Changes can take place that may affect the EQ configuration of equipment as a result of design modifications, changes in safety analysis, storage, equipment maintenance, etc. The configuration management and ongoing equipment performance monitoring must ensure that EQ configuration is maintained.

In conclusion, there is a structured and comprehensive EQ program in Pickering NGS. The EQ process is maintained on an ongoing basis, such that the effects of equipment aging are accounted for.

D-237 – Control of Accidents Within the Design Basis

Principle: Provisions are made at the design stage for the control of accidents within the design basis, including the specification of information and instrumentation needed by the plant staff for following and intervening in the course of accidents.

For Pickering NGS, DBAs and the plant response under DBA conditions, are detailed in Part 3 of the Safety Reports [NK30-SR-01320-00003-R004, *Pickering Nuclear 5-8 Safety Report: Part 3 Accident Analysis Vol 1-5*, October 10, 2014], [NA44-SR-01320-00002-R004, *Pickering Nuclear 1-4 Safety Report: Part 3 – Accident Analysis*, October 31, 2013]. For Pickering NGS, accidents within the design basis are classified as single failure (i.e., a single process failure) and dual failure (i.e., a process failure combined with a coincidental impairment of a Special Safety System). Safety system impairments considered include a failure of the system to perform its safety function.

Accidents within the design basis include events that have a potential of occurring during the lifetime of the plant, events that would be classified as DBAs, and some dual failures that are BDBAs in the CNSC REGDOC-2.4.1 terminology.

Control systems are provided in the design to prevent the more frequent events from requiring Special Safety System action, in particular, the setback/stepback feature of Reactor Regulating System. Similarly, the Special Safety Systems together with their support systems are capable of controlling the more challenging accidents within the design basis, and preventing them from progressing further.

The control systems and Special Safety Systems are designed to perform their function automatically in the short term for most postulated accidents. Analyses demonstrating the effectiveness of the automatic response of the Special Safety Systems are documented in Part 3 of the Pickering NGS Safety Reports. By their nature, certain postulated accidents would require operator action in the short term. A required operator action is credited in the safety analysis no sooner than 15 minutes following the first unambiguous indication of the event if the action can be performed from the Main Control Room, or 30 minutes if field actions are required. A required operator action is one that is credited in the analysis and which if not credited, would result in accident consequences that could not be shown to be predicted (or bounded) by other analyses documented in Part 3 of the Safety Report.

Required operator actions are tabulated in Part 3, Section 1 of the Safety Reports, including the required timing and definition of the clear, unambiguous signals to the operator to identify the given accident.

The clear, unambiguous signals designed to allow the operator to respond to the event are identified in the Operating Manuals and Abnormal Incident Manuals (see Safety Principle O-288, Normal Operating Procedures, which also addresses Safety Principle O-290, Emergency Operating Procedures). To provide post-accident monitoring capability, the critical safety parameters are displayed in the Main Control Room. For Units 1,4, the SDSE Instrument Rooms also provide for monitoring of the critical safety parameters (a list of critical safety parameters for Units 1,4 is provided in Safety Principle D-227, Monitoring of Plant Safety

Status). The SDSE Instrument Rooms house SDSE trip parameters signal processing instrumentation, trip logic and monitoring computers. Buffered/isolated signals are transmitted from the SDSE Instrument Room to the Main Control Room to provide indications of the SDSE parameters. These instrument rooms provide separation from SDSA instrumentation and trip logic. In Units 5-8, the Unit Emergency Control Centre rooms contain unit controls and logic panels and provision for monitoring of critical parameters (see Safety Principle D-227, Monitoring of Plant Safety Status).

It is concluded that adequate provisions for the control of accidents within the design basis are provided at Pickering NGS. The operator has indications and alarms as well as the capability to perform actions from the Main Control Room for this purpose.

D.11. Safety Principles Related to Level 4

The following safety principles are related to defence-in-depth Level 4:

- AM-318 – Strategy for Accident Management
- AM-323 – Training and Procedures for Accident Management
- AM-326 – Engineered Features for Accident Management

As demonstrated below, Pickering NGS design and operation are aligned with all safety principles related to Level 4.

AM-318 – Strategy for Accident Management

> *Principle: The results of an analysis of the response of the plant to potential accidents beyond the design basis are used in preparing guidance on an accident management strategy.*

As per [N-PROG-MP-0014-R006, *Reactor Safety Program*, July 18, 2016], the Reactor Safety Program provides the framework for major aspects of safe operation. One element of the reactor safety program relates to the management of BDBAs and severe accidents. In this context, a BDBA refers to a relatively low frequency event sequence that is not included in the plant design basis (due to the low frequency of occurrence) and is not necessarily bounded by the analyses of the station design basis. If the consequences of such events are significant core degradation, these BDBAs are referred to as severe accidents. The term design extension condition is introduced (as per CNSC REGDOC-2.5.2, *Design of Reactor Facilities: Nuclear Power Plants*) to describe a sub-set of BDBA conditions for which specific SSCs, referred to as complementary design features, are provided for mitigation.

OPG's response to BDBAs is detailed in [N-STD-MP-0019 R002, *Beyond Design Basis Accident Management*, August 19, 2016]. The written guidance that implements the strategies for managing BDBAs is referred to as Emergency Mitigating Equipment Guidelines and Severe Accident Management Guidelines. Application of Emergency Mitigating Equipment Guidelines and Severe Accident Management Guidelines may require temporary changes to permit operation of specific SSCs or Emergency Mitigating Equipment to implement Emergency Mitigating Equipment Guidelines/Severe Accident Management Guidelines objectives. For permanent changes to SSCs to facilitate Emergency Mitigating Equipment Guidelines/Severe Accident Management Guidelines, [N-GUID-01130-10000-R001, *Modifications for Beyond Design Basis Accidents*, March 17, 2015] provides guidance related to the design, modification, procurement, operation and testing of SSCs, for responding to BDBAs.

The physical processes that govern severe accident phenomena are complex and, consequently, Severe Accident Management Guidelines are designed to be flexible, accommodating a wide range of severe accident causes and progression. Supporting analysis for BDBAs has been prepared as part of the PSAs [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014]. Reasonable strategies for coping with severe accident progression have been identified and developed using “state of the art” reviews, PSAs and insights on accident behaviours from accident analyses that are presented in the COG Severe Accident Management Guidance Technical Basis Documents.

Following the March 11, 2011 accident at the Fukushima Daiichi nuclear power plant, the CNSC requested all Canadian utilities to complete an assessment to review the impact of a similar event (i.e., an event resulting in a total loss of power, subsequently resulting in a total loss of heat sinks to cool the fuel post-shutdown) at their respective stations. OPG Report [P-REP-03490-10012-R01, *Fukushima Daiichi - Total Loss of Heat Sink Assessment for Pickering A and Pickering B*, June 14, 2013] consolidates the results from various evaluations performed to date and establishes the time line for progression of a total loss of heat sink event. P-REP-03490-10012-R01 also identifies mitigating provisions which could be put in place to prevent progression to a severe accident. Provisions to maintain or re-establish the Control, Cool, Contain and Monitoring safety functions were examined to determine those that are most practical to implement and also meet specified requirements.

From a PSA perspective, the Pickering 1,4 and 5-8 Risk Assessment has been updated as part of the Fukushima Action Item update [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan,* April 30, 2014]. The PSA for Pickering NGS Units 1,4 and 5-8 has incorporated the risk benefits gained from the Fukushima Action Item enhancements (e.g., BDBA procedures/guides and Emergency Mitigating Equipment).

To summarize, BDBAs have been analyzed for Pickering NGS. The station operating procedures, Emergency Mitigating Equipment Guidelines and Severe Accident Management Guidelines are supported by analysis of BDBA progression.

AM-323 – Training and Procedures for Accident Management

Principle: Nuclear plant staff are trained and retrained in the procedures to follow if an accident occurs that exceeds the design basis of the plant.

BDBA management strategies are described in OPG Standard [N-STD-MP-0019-R002, *Beyond Design Basis Accident Management*, August 19, 2016] and implemented through operating procedures, Emergency Mitigating Equipment Guidelines and Severe Accident Management Guidelines, which are used to respond to all BDBAs, including design extension conditions and severe accidents.

The adequacy of the response and mitigation strategies that have been developed is demonstrated primarily through drills and exercises. The Emergency Preparedness Department assesses the Emergency Response Organization performance to the established objectives identified in OPG Instruction [N-INS-03490-10002-R005, *Conduct of Emergency Preparedness Drills and Exercises*, December 31, 2014] and reviews all drill and exercise related Station Condition Records and Action Requests to monitor status and ensure completeness. These assessments are documented in the Emergency Preparedness Drill and Exercise Performance Objectives Reports. Deficiencies found during drills and exercises are documented using the Station Condition Record System in accordance with OPG Procedure [N-PROC-RA-0022-R034, *Processing Station Condition Records*, March 24, 2017]. Corrective Action plans are developed and corrective actions are initiated and tracked to completion.

The drills and exercises outlined above are a component of the overall training for accident management. As described in Safety Principle O-278, Training, OPG Program [N-PROG-TR-0005-R016, *Training*, January 5, 2016] summarizes how training needs are addressed at OPG. All tasks to be performed are subjected to an analysis to determine the training requirements, documented in documents designated as Job Training Analysis. Through this process, of the order of fifty separate tasks have been identified for Emergency Mitigating Equipment Guidelines/Severe Accident Management Guidelines. Following the training analysis, a training package designated as “OVH” has been generated for each task to ensure the identified tasks are properly executed.

[N-TQD-503-00001 R017, *Nuclear Emergency Response Organization Training and Qualification Description*, January 12, 2016] establishes training and qualification requirements for Emergency Response Organization individuals assigned to response positions, including Emergency Response Organization staff in accordance with OPG Program [N-PROG-RA-0001-R015, *Consolidated Nuclear Emergency Plan*, December 22, 2016]. Initial training is designed to ensure that Emergency Response Organization personnel have the knowledge and skills needed to independently perform tasks associated with the identified Emergency Response Organization position. Continuing training maintains and enhances knowledge, skills and performance standards required to perform tasks of Emergency Response Organization positions. The program also facilitates confirmation that incumbents retain the knowledge and skills required for correct execution of tasks associated with assigned emergency response roles. Continuing training includes:

- Important lessons learned from drills and exercises
- Real events
- Industry experience
- Position-specific procedures and changes

- Associated equipment changes
- Performance standards changes

In conclusion, training is in place at Pickering NGS to support Beyond Design Basis response. This includes training in the use of operating procedures, Emergency Mitigating Equipment Guidelines and Severe Accident Management Guidelines. Drills and exercises are important elements of the training conducted for accident management.

AM-326 – Engineered Features for Accident Management

Principle: Equipment, instrumentation and diagnostic aids are available to operators, who may at some time be faced with the need to control the course and consequences of an accident beyond the design basis.

Pickering NGS Units 1,4 and 5-8 has complementary design features for BDBAs. If actions identified in Operating Manuals and Abnormal Incident Manuals are unsuccessful in terminating the accident progression, actions will be taken per the Emergency Mitigating Equipment Guidelines to prevent the accident from progressing to a severe accident. The Emergency Mitigating Equipment Technical Basis Document [N-BDB-03600-00002-R000, *OPG Emergency Mitigating Equipment for Beyond Design Basis Accidents – Technical Basis Document*, October 2015] summarizes the technical basis for Emergency Mitigating Equipment, including:

- The bounding BDBA event sequence and associated analyses.
- The overall functional requirements for the Emergency Mitigating Equipment.
- Other information relevant to Emergency Mitigating Equipment specification, design and procurement.

Critical safety parameters and associated instrumentation for monitoring plant response in BDBAs have also been identified as discussed in the Emergency Mitigating Equipment Technical Basis Document.

A key line of defence for BDBAs is Emergency Boiler Makeup using Emergency Mitigating Equipment. An additional line of defence is Emergency Mitigating Equipment to provide makeup to the Heat Transport System and to the Moderator. These features are capable of limiting core damage and allowing for Containment pressure control for most BDBAs.

In addition, implementation of Phase 2 Emergency Mitigating Equipment modifications is in progress. Phase 2 Emergency Mitigating Equipment includes restoration of power to critical station equipment for core cooling and monitoring, and for restoring operation of Containment coolers to improve control of Containment pressure following BDBAs.

Additional major Fukushima Project modifications include:

- Passive Auto-catalytic Recombiners have been installed on all units to supplement the existing Hydrogen Igniters for control of hydrogen in Containment.
- Enhancements to water makeup/cooling capability for the IFBs have been installed.

Instrumentation and diagnostic aids to support deployment of Emergency Mitigating Equipment are available to the operator as described in the review of Safety Principle D-227, Monitoring of Plant Safety Status.

In conclusion, the modifications completed prior to and in response to the 2011 Fukushima accident, together with additional Emergency Mitigating Equipment, provide enhanced capability for BDBA Management. Ongoing addition of Phase 2 Emergency Mitigating Equipment will further enhance safety margins.

D.12. Safety Principles Related to Level 5

The following safety principle is related to defence-in-depth Level 5:

- S-140 – Feasibility of Emergency Plans

As demonstrated below, Pickering NGS design and operation are aligned with the safety principle related to Level 5.

S-140 – Feasibility of Emergency Plans

Principle: The site selected for a nuclear power plant is compatible with the offsite countermeasures that may be necessary to limit the effects of accidental releases of radioactive substances, and is expected to remain compatible with such measures.

The original plant did not explicitly consider the feasibility of emergency plans as part of the site selection criteria. The Consolidated Nuclear Emergency Plan [N-PROG-RA-0001-R014, *Consolidated Nuclear Emergency Plan*, May 2015] ensures compatibility with the offsite countermeasures that are necessary to limit the effects of accidental releases of radioactive substances on a continuing basis. The Consolidated Nuclear Emergency Plan provides a basis for OPG Nuclear to implement and maintain its emergency response capability to protect the public, employees and the environment in the event of a nuclear emergency.

The Main Control Room team utilizes resources of the on-site Emergency Operations Centre to mobilize and deploy the necessary emergency teams. The Emergency Operations Centre personnel may, if necessary, mobilize, brief and deploy Emergency Response Teams to address specific emergencies, such as a fire, medical emergency, or a search and rescue operation. Appropriate off-site support groups (i.e., non-OPG resources) such as fire and/or ambulance may be activated to respond to the site. The Main Control Room and the Emergency Operations Centre are equipped with the necessary communications and other equipment as described in Section 1.5 of the Consolidated Nuclear Emergency Plan. On-site and off-site Emergency Response Facilities are discussed further under Safety Principle EP-336, Emergency Response Facilities.

The adequacy of the response and mitigation strategies that have been developed is demonstrated primarily through drills and exercises, which are conducted in accordance with OPG Procedure [N-PROC-RA-0045 R010, *Emergency Preparedness Drills and Exercises*, December 2015]. The Emergency Preparedness Department assesses the Emergency Response Organization performance to the established objectives identified in OPG Instruction [N-INS-03490-10002-R005, *Conduct of Emergency Preparedness Drills and Exercises*, December 31, 2014] and reviews all drill and exercise related Station Condition Records and Action Requests to monitor status and ensure completeness. These assessments are documented in the Emergency Preparedness Drill and Exercise Performance Objectives Reports.

To take into account major changes at site and around the site, OPG Approved Roles Document [N-MAN-08131-10000 Sht. S4-0245 R002, *Manager, Emergency Preparedness*, November 3, 2014] provides specific accountability to the Department Manager of Emergency Preparedness to interface with the regulator and other external stakeholders as necessary to ensure that the relevant regulatory and licensing requirements are built into the emergency preparedness program and stakeholder interfaces are effectively managed.

The Department Manager of Emergency Preparedness is a member of the Toronto and Durham Regional Nuclear Emergency Management Coordinating Committees as well as the Provincial Nuclear Emergency Management Coordinating Committee. These committees meet on a regular basis and review issues that could impact emergency response, including local development which may modify/increase risks. In addition, OPG's OPEX process monitors events around the world to determine if there is any unforeseen event that may have applicability to Pickering NGS. If/when an event is deemed to be applicable, the emergency response process is reviewed to ensure the event can be adequately dealt with.

To summarize, the Pickering NGS emergency plans are tailored for the characteristics of the surrounding area where countermeasures would be taken. Changes in these characteristics are factored into the emergency planning on an ongoing basis.

Appendix E – Strengths Used in the Defence-in-Depth Assessment

Strength ID	Strength Title and Description	Justification	Level
S-01	**Management** The Pickering Station Leadership Team has effectively aligned the organization to significantly improve performance in several focus areas.	At Pickering, the leadership team has effectively aligned the organization to improve performance in several focus areas. Actions in support of these focus areas have been incorporated into department human performance plans and include: • Coaching to Enhance Nuclear Professionalism and Performance • Opportunities to leverage good practices • Analysis, Corrective Action Planning and Feedback of Performance Information • Critical Engaged Thinking & Human Performance Tools • Radiological Worker Practices The Safety Factor 10 Report states that OPG has a well-defined organizational structure and strong lines of authority. Operation and maintenance of the station are conducted as per regulatory requirements and Nuclear standards for public safety are directed by the Director, Operations and Maintenance, who also coordinates with the centre-led organizations to effectively use resources to achieve performance targets. The quality and quantity of services provided by these centre-led support organizations is monitored by the Pickering Senior Site Vice President, who holds responsibility for establishing site requirements and priorities. OPG identifies qualified and competent individuals for key positions with career development and succession planning being key elements in the management capability strategy. The corporate succession plan ensures that individuals with high leadership potential are identified to help continue excellence in nuclear safety. Managers at OPG ensure that tasks are executed as defined through	1, 2, 3, 4, 5

Strength ID	Strength Title and Description	Justification	Level
		programs that are specifically designed to achieve higher levels of Nuclear and industrial safety, higher unit reliability, and reduced operating costs through event-free operation. This performance is accomplished through pre-job briefings, post-job debriefings, self-checking programs, communications, self-assessments, and an observation and coaching program. The Human Performance Program at Pickering has been implemented to continually reduce human performance events and errors by managing defences, in pursuit of zero events. The number of challenges to safe, reliable and effective operation of the Pickering station has been reduced, and the significance of these challenges has also been reduced due to Pickering NGS leadership team's commitment to, and focus on, risk awareness, risk mitigation and worker training. The resultant improved station performance is reflected in improving trends in our established metrics on both Forced Loss Rate and Site Event Free Day Resets. Other utilities have benchmarked Pickering NGS Operations Management and Leadership successes for implementation at their facilities. **Sources:** Section 4.1.1 and 4.1.2 of PSR2 Safety Factor 10 Report [P-REP-03680-00014 R000, *Pickering NGS PSR2 Safety Factor 10 Report: Organization, Management System, and Safety Culture*, December 2016] 2013 Public Hearing on Pickering Licence Renewal	
S-02	**Effective Equipment Reliability Program** Pickering NGS' Equipment Reliability Program implementation and execution of the program is a station priority.	The Equipment Reliability program [N-PROG-MA-0026-R002, *Equipment Reliability*, May 26, 2015] ensures that there are defined activities ensuring that equipment aging issues are identified, understood and effectively managed for equipment important to nuclear safety and equipment reliability. Any Aging Management station actions are captured in the system health reports and managed through the Work Management program. The Equipment Reliability	1, 2, 3, 4

Strength ID	Strength Title and Description	Justification	Level
	The station management team monitors implementation, and leaders enforce accountability. Obsolescence Management and Performance Monitoring, Condition Assessments, and Predictive Maintenance are also noted as taking into consideration the long-term aging management assessments.	Program contains the following elements which ensure ongoing high levels of reliable performance of critical components: • Identifying critical components that require focused attention. • Specifying the required maintenance strategies to maintain high levels of reliability. • Executing Predictive Maintenance (PdM), and Preventive Maintenance (PM) programs. • Monitoring system and component condition and implementing plans to restore and maintain system and component health. • Taking prompt and effective action, when critical equipment fails, to understand the technical and organizational causes and to prevent a recurrence. • Identifying and predicting aging and obsolescence issues on important components and embedding mitigating strategies and actions into the business plan. Multidisciplinary System Health and/or Component Health Teams are established for important systems to provide input to and support for system health activities. These teams are comprised of cross functional individuals from Engineering, Maintenance, Operations (Licensed and Non-Licensed), Work Control and Supply Chain. In addition, as stated in the Safety Factor 2 Report, detailed Condition Assessments are being completed as part of the ongoing Aging Management Program to include full power operation of Pickering NGS to 2028. In recent years, operating performance at Pickering has significantly improved as illustrated by the decreasing Forced Loss Rate. The key contributors to this improved performance are the improvements in equipment reliability and improvements in Human Performance, leading to fewer events and errors. This is a result of improvements in Operations Management and Leadership which has led to a strongly focused organization.	

Strength ID	Strength Title and Description	Justification	Level
		The effectiveness assessment in Safety Factor 4 concludes that the Equipment Reliability Program has been effectively implemented. This conclusion is supported by the presence of comprehensive and effective programs developed and implemented to ensure that the condition of components meets design requirements. Operational improvements are implemented continuously based on national and international OPEX, in addition to those driven by the evolving regulatory requirements (e.g., CNSC RD-334 and CNSC REGDOC-2.6.3.) Also, Pickering NGS is assessed to be in conformance with safety-significant requirements of CNSC RD/GD-210. **Source(s):** PSR2 Safety Factor 2 Report [P-REP-03680-00005 R001, *Pickering NGS PSR2 Safety Factor 2 Report – Actual Condition of Structures, Systems, and Components Important to Safety,* March 2017] PSR2 Safety Factor 4 Report [P-REP-03680-00007 R000, *Pickering NGS PSR2 Safety Factor 4 Report: Aging*, July 2016]	
S-03	**Major Components Program** Strong governance framework with comprehensive programs is in place for Major Component Life Cycle Management Plans, addressing the full spectrum of disciplines, including administrative, engineering, inspection, maintenance, training, quality assurance, engineering change control in conjunction with	The program [N-PROG-MA-0025-R002, *Major Components*, March 25, 2015] is fully developed and effectively implemented for continued validation of fitness for service of the Major Components (Fuel Channels, Feeders, Steam Generators and reactor structures). The program incorporates the reporting requirements associated with demonstrating compliance with design basis documentation relevant to each of the Major Components Program areas. A mature and effective Steam Generator inspection and maintenance program, as part of the Major Components Program, is successful in managing Fitness for Service of the Steam Generators to end of planned service life. The most recent Fleetview Program Health and Performance Report for 2015 [N-REP-08130-0635343 R000*, Fleetview Program Health and Performance*	1, 2, 3, 4

Strength ID	Strength Title and Description	Justification	Level
	application of OPEX and research findings.	*Report (Q1/2016 to Q4/2016)*, January 2017] reported the following significant program accomplishments: • The training program aligned with industry best practices. • The Steam Generator life cycle management plan was recognized as a very robust and well-managed program with a strong team of competent staff by internal and external reviewers. • Major Components Program staff continues to maintain a strong working relationship with peer teams and external working groups and governing bodies, which supports effective OPEX sharing, overall program improvement and program execution efficiency. In the period of 2015, Major Components program completed benchmarking of pressure tube, Feeder, and boiler inspection programs with Bruce Power, as well as CANDU utilities in China, Korea, India, and Romania. Based on this benchmarking opportunity, OPG units were found to be in alignment with industry practices. • Major Components working groups are well established and are fully effective and working together to continuously improve/sustain industry best program performance. In 2016, OPG's Major Component staff members participated in numerous peer team meetings during conferences, workshops, and working group activities. **Source(s):** Section 4.1.10 of Safety Factor 4 Report [P-REP-03680-00007-R000, *Pickering NGS PSR2 Safety Factor 4 Report: Aging*, July 2016] Section B.7 of Code and Standard Reviews Associated with Safety Factors 2, 3, and 4 [P-REP-03680-00004-R000, *Pickering NGS Periodic Safety Review 2: Code and Standard Reviews for Safety Factors 2 (Actual Condition of SSCs), 3 (Equipment Qualification) and 4 (Aging),* July 2016]

		Section 4.1.1.2.49 of PSR2 Safety Factor 2 Report [P-REP-03680-00005-R001, *Pickering NGS PSR2 Safety Factor 2 Report – Actual Condition of Structures, Systems, and Components Important to Safety,* March 2017]	
S-04	**System and Component Health Reporting** The conditions of the Pickering NGS SSCs are tracked in System and Component Health Reports that are aligned with industry best practices.	The Equipment Reliability Program [N-PROG-MA-0026-R002, *Equipment Reliability*, May 26, 2015] at OPG is supported by system health reporting [N-PROC-MA-0024, *System Performance Monitoring*, December 9, 2016] and component program health reporting [N-PROG-MA-0017 R009, *Component and Equipment Surveillance*, May 31, 2017] governance. These processes are fully developed and effectively implemented ensuring that equipment reliability issues are identified, understood and effectively managed for critical equipment. Aging Management actions from Condition Assessments are captured in the System and Component Program Health Reports, and managed through the Work Management program. The System Health Reports are managed through a structured, standardized reporting program (SystemIQ) for system monitoring and performance to ensure that systems important to safety will perform their intended functions under the design basis. SystemIQ is a software application that is designed to assist System Engineers and Managers in optimizing the operational performance and condition of plant systems. SystemIQ centralizes, standardizes, and automates System Health Reporting, Performance and Condition Monitoring, and the generation and organization of System Notebooks. Similarly, the ProgramIQ application is used to document and report on Component Program health. **Source(s):** PSR2 Safety Factor 4 Report [P-REP-03680-00007-R000*, Pickering NGS PSR2 Safety Factor 4 Report: Aging*, July 2016]	1

Strength ID	Strength Title and Description	Justification	Level
S-05	**Implementation of Fukushima Action Items** Pickering NGS has implemented and is continuing to enhance significant provisions to prevent and mitigate severe accident progression and protect Containment integrity and enhance defence-in-depth against BDBAs.	Emergency Mitigating Equipment has been provided for an additional makeup water supply to cool the reactor Fuel for BDBAs. Additional major Fukushima Project design modifications that have been installed include enhancements for emergency electrical power supplies for critical parameter monitoring and for water makeup/cooling capability for the IFBs. In addition, implementation of Phase 2 Emergency Mitigating Equipment modifications is in progress. Phase 2 Emergency Mitigating Equipment includes restoration of power to station systems for continued fuel cooling and monitoring and restoration of Containment coolers to enhance control of Containment pressure following BDBAs. All Fukushima Action Items assigned to OPG for Emergency Mitigating Equipment are now closed (per final FAI status report). OPG has been recognized internationally for work done in response to the 2011 Fukushima accident. **Source(s):** Section 4.1.4 and 4.1.7 of PSR2 Safety Factor 1 Report [P-REP-03680-00008-R000, *Pickering NGS PSR2 Safety Factor 1 Report: Plant Design,* March 2017] Fukushima Action Item Status Report [N-REP-03600-10003-R007, *Fukushima Action Item Status Report,* November 2015]	4, 5
S-06	**Deterministic Safety Analysis** The deterministic safety analysis is robust and effectively implemented.	The OPG deterministic safety analysis complied with the regulatory requirements of S-310, one of the predecessors to REGDOC-2.4.1. With the evolution from S-310 to RD-310, and then to REGDOC-2.4.1, OPG prepared an implementation plan to address the evolving changes, applying a graded approach. The programmatic elements that comply with REGDOC-2.4.1 are in place. The Deterministic Safety Analysis in the Safety Reports is comprehensive, covering a full range of DBAs. The CNSC has also concluded	1, 2, 3, 4

Strength ID	Strength Title and Description	Justification	Level
		in a review of OPG's Safety Analysis Program Implementation that "OPG has a robust and effectively implemented program in place". The conclusion of the Safety Factor 5 Report is that the deterministic safety analysis program and supporting programs/procedures at OPG are comprehensive, resulting in a systematic and disciplined approach to identifying, prioritizing and addressing any safety analysis related issues. The CNSC also stated that for Safety Analysis Program Implementation, OPG staff and their service providers demonstrated a clear commitment to safety. Furthermore, the Regulatory Oversight Report for Canadian Nuclear Power Plants: 2015 states that CNSC staff concluded that the "Safety Analysis" Safety and Control Area at Pickering met or exceeded performance objectives and all applicable regulatory requirements, and rated this Safety and Control Area as Fully Satisfactory. **Source(s):** Section B.3 of Code and Standard Reviews Associated with Safety Factors 1, 5, 6, and 7 [P-REP-03680-00029-R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 1, 5, 6, and 7,* March 2017] Section 5 of PSR2 Safety Factor 5 Report [P-REP-03680-00009-R000, *Pickering NGS PSR2 Safety Factor 5 Report: Deterministic Safety Analysis,* March 2017] CNSC Correspondence on Results of the CNSC Review of OPG's Safety Analysis Program Implementation [N-CORR-00531-18039, *Darlington and Pickering NGS: Results of the CNSC Review of OPG's Safety Analysis Program Implementation,* April 15, 2016] CNSC Regulatory Oversight Report for 2015	

Strength ID	Strength Title and Description	Justification	Level
S-07	**Probabilistic Safety Assessment** The PSA program meets or exceeds performance objectives. OPG has developed and implemented a process of maintenance of the probabilistic risk assessment model to ensure that the model is representative of the actual plant configuration and operation and testing at the station.	PSR2 shows that the PSA programs and procedures at OPG are comprehensive, resulting in a systematic and disciplined approach to identifying, prioritizing and addressing any PSA-related issues. The conclusion of the Safety Factor 6 Report is that there are processes to assess the impact of changes in plant design, operation, and plant-specific failure data and to update the PSA to reflect the current plant status. The intent of Safety Factor 6 Report Review Task 2 assessment, which requires confirmation of the existence of processes to assess the impact of changes in plant design, operation and failure data, is met and therefore Pickering NGS is compliant. In addition, a self-assessment concluded that Pickering NGS has good alignment with current governance and best industry practices; recent procedural changes are reflected in the work program; and the Pickering Risk and Reliability Program execution satisfies the intent of the governance. PSA models and results for Pickering have also played a significant role in deriving the Emergency Mitigating Equipment Guidelines and Severe Accident Management Guidelines that are in place to manage accident response for a potential BDBA. The Regulatory Oversight Report for Canadian Nuclear Power Plants: 2015 states that CNSC staff concluded that the “Safety Analysis” Safety and Control Area, including PSA, at Pickering met or exceeded performance objectives and all applicable regulatory requirements, and rated this Safety and Control Area as Fully Satisfactory. **Source(s):** Sections 4.1.1, 4.1.2, and 4.1.3 of PSR2 Safety Factor 6 Report [P-REP-03680-00010-R000, *Pickering NGS PSR2 Safety Factor 6 Report: Probabilistic Safety Assessment*, March 2017] Section B.4 of Code and Standard Reviews Associated with Safety Factors 1, 5, 6, and 7 [P-REP-03680-00029-R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 1, 5, 6, and 7,*	1, 2, 3, 4

		March 2017] CNSC Regulatory Oversight Report for 2015 CNSC Correspondence on Results of the CNSC Review of OPG's Safety Analysis Program Implementation [N-CORR-00531-18039, *Darlington and Pickering NGS: Results of the CNSC Review of OPG's Safety Analysis Program Implementation,* April 15, 2016]	
S-08	**Operationalization of Probabilistic Safety Assessment** Probabilistic Safety Assessment (PSA) is used to support conduct of engineering, maintenance and operation.	PSA is used to support the conduct of engineering, maintenance and operation at Pickering NGS as follows: • Proposed modifications to plant operation, configuration or procedures that may change the operation of the plant are reviewed to quantify impact on risk and to assess its acceptability. For any modifications that may reduce risk, a PSA is performed to quantify the benefits in terms of impact on risk as in input to decision-making. • PSA assumptions important to safety regarding inspection, testing and maintenance are identified and incorporated into operating and maintenance procedures. • PSA is used to identify accident scenarios. • PSA is used to support in-plant and ex-plant consequence analyses for event sequences beyond the design basis for use in understanding accident progression and management, as allowed by the scope and limitations of the PSA. • Risk information is used in safety decision-making based on the PSA data, models and results. • PSA is used for outage risk assessment and for on-line maintenance risk assessment as required.	1, 2, 3, 4

Strength ID	Strength Title and Description	Justification	Level
		• PSA is used for managing instantaneous risk from discovery issues related to a change in design bases, analysis results, experimental findings or knowledge interpretations. • PSA is used to assess the risk of Equipment Out Of Service and abnormal plant configurations. A Risk Management Matrix is established for Pickering NGS for discussion during daily Station Alignment Meetings. Furthermore, the Regulatory Oversight Report for Canadian Nuclear Power Plants: 2015 states that CNSC staff concluded that the “Safety Analysis” Safety and Control Area, including PSA, at Pickering met or exceeded performance objectives and all applicable regulatory requirements, and rated this Safety and Control Area as Fully Satisfactory. **Source(s):** Section 4.1.2 of PSR2 Safety Factor 6 Report [P-REP-03680-00010-R000, *Pickering NGS PSR2 Safety Factor 6 Report: Probabilistic Safety Assessment,* March 2017] OPG Correspondence, Pickering NGS: Risk Improvement Plan Update [P-CORR-00531-04946, *Pickering NGS: Risk Improvement Plan Update*, February 28, 2017] CNSC Regulatory Oversight Report for 2015	
S-09	**Implementation of Safe Operating Envelope Program** Comprehensive program in place for systematic application of Safe Operating Envelope (SOE) definition, implementation and maintenance (to end of station	SOE is defined by the Operational Safety Requirements, Instrument Uncertainty Calculations and other safety-related limits and system credits that ensure operation within the Safety Analysis Basis. Safe Operating Limits and Conditions of Operability (SOE Limits) bound administrative limits in station operating documentation, which provide plant operators with the information required to ensure safe operation of the plant in conformance with the requirements of the Safety Analysis.	1,2,3

Strength ID	Strength Title and Description	Justification	Level
	life).	Rigorous programs and processes are in place to control and verify design compliance to ensure that the plant design remains within the bounds of the SOE. The SOE program is fully developed and effectively implemented. A compliance framework whereby plant operation within the requirements established as part of the SOE is verified on a regular basis and appropriate corrective actions are initiated upon discovery of plant operation outside of the SOE. While operational limits have always been part of the Operating Policies and Principles, a formal SOE program was not part of the original design or licensing basis for Pickering NGS. Pickering NGS Licence Conditions Handbook (states, “SOE is a new requirements introduced in the current PROL. OPG has had an implemented SOE program since 2012”. PSR2 assessment of CSA N290.15, *Requirements for the Safe Operating Envelope of Nuclear Power Plants*, confirms conformance with the safety-significant requirements of the code. This code is part of on-going CNSC compliance monitoring activities. Furthermore, the Regulatory Oversight Report for Canadian Nuclear Power Plants: 2015 states that CNSC staff concluded that the “Safety Analysis” Safety and Control Area and “Operating Performance” Safety and Control Area at Pickering met or exceeded performance objectives and all applicable regulatory requirements, and rated these Safety and Control Areas as Fully Satisfactory. **Source(s):** Section 4.1.2 of PSR2 Safety Factor 5 Report [P-REP-03680-00009-R000, *Pickering NGS PSR2 Safety Factor 5 Report: Deterministic Safety Analysis*, March 2017] CNSC Regulatory Oversight Report for 2015	

Strength ID	Strength Title and Description	Justification	Level
S-10	**Healthy Safety Culture** Pickering has a healthy Nuclear Safety Culture and a respect for nuclear safety and there is a strong bias to put safety over production. Pickering has formally implemented Nuclear Safety Culture Monitoring Panels for regular monitoring of safety behaviour to promote use of error-free performance tools, risk-informed decision making and questioning attitude in day-to-day activities throughout the organization.	Pickering management is committed to continuously strengthen the safety culture within the Pickering organization. The Safety Factor 10 Report paraphrases a nuclear safety culture assessment as follows: “This assessment consisted of a survey, interviews and field observations…65 on-site interviews and 18 field observations were completed by a team of 17 individuals composed of both internal and external team members. In conclusion, the assessment team determined that Pickering has a healthy nuclear safety culture and a respect for nuclear safety not compromised by production priorities.” This is corroborated by the CNSC noting that OPG has a strong commitment to safety. Pickering’s healthy safety culture is maintained through effective leadership, management and communication of expectations in areas including: • A high level of human performance and nuclear, conventional, radiological and environmental safety performance • A high level of equipment availability • Adequate staff numbers and staff knowledge and capability The Event Free Day Reset (EFDR) indicator is one of the flags OPG uses to identify human performance events. The indicator reflects the effectiveness of management in reducing errors and improving organizational processes and activities to reduce the significance and frequency of human performance events. Performance improvement has been accomplished by effectively identifying human performance events, investigating the causes to determine corrective actions, performing trending and analysis to identify reoccurring and common issue areas and communicating the results throughout all levels of the organization. The associated indicators have continually improved at Pickering NGS. These improvements provide evidence that attention to Safety	1, 2, 3, 4

Strength ID	Strength Title and Description	Justification	Level
		Culture is having tangible benefits, supporting that Safety Culture is a Strength. **Source(s):** Section 4.1.8 of PSR2 Safety Factor 10 Report [P-REP-03680-00014-R000, *Pickering NGS PSR2 Safety Factor 10 Report: Organization, Management System, and Safety Culture,* December 2016]	
S-11	**Relationship with Stakeholders and Public** OPG has fostered a strong relationship with stakeholders and interested public. A longstanding positive relationship with the community is in place to promote communication, education and awareness regarding the role of nuclear power and the overriding priority being placed on safety and environment.	OPG demonstrates open and transparent communication in a timely manner to maintain positive and supportive relationships, as well as the confidence of key stakeholders. OPG is ethical and credible in its relationships with employees, suppliers, customers and the public with whom it does business and in the communities in which it operates. Corporate Stakeholder Relations develops, maintains and implements a public information program that is conducted in accordance with the ethical principles of integrity, excellence and citizenship outlined in the OPG Code of Business Conduct. A highly active stakeholder engagement system is in place in terms of active community engagement, communication and responding to the public on environmental matters and making information on environmental monitoring and emissions data easily accessible for the public, all at a level beyond regulatory requirements. The Pickering Community Advisory Council assists Pickering NGS in identifying and responding effectively to the concerns of the community. Communication activities to support the Pickering Waste Management Facility are undertaken periodically. The Pickering Neighbours Newsletter is issued to the community. In community publications, print ads have been run to promote OPG's Biodiversity and tree planting program. The Pickering Nuclear Information Centre continues to provide public access for further information. OPG/Pickering actively uses social media (e.g., Twitter, Instagram) to connect	4, 5

Strength ID	Strength Title and Description	Justification	Level
		with a wide range of audiences. Other information and updates continue to be made available on www.opg.com. **Source(s):** Pickering Nuclear Community Advisory Council Terms of Reference www.opg.com 2013 Public Hearing on Pickering Licence Renewal	
S-12	**Dose to Public** The dose to the off-site public resulting from operation of the station is very much less than the dose from background radiation.	Safety Factor 14 Report notes this conclusion based on similar text in the externally-prepared Pickering Environmental Risk Assessment. Specifically, the Environmental Risk Assessment states: “Since the dose estimates are a small fraction of the regulatory public dose limit and natural background exposure, no discernible health effects are anticipated due to exposure of potential groups to radioactive releases from the PNGS.” Furthermore, the Regulatory Oversight Report for Canadian Nuclear Power Plants: 2015 states that CNSC staff concluded that the “Radiation Protection” Safety and Control Area at Pickering met or exceeded performance objectives and all applicable regulatory requirements, and rated this Safety and Control Area as Fully Satisfactory. **Source(s):** Section 4.1.7 of PSR2 Safety Factor 14 Report [P-REP-03680-00018-R000, *Pickering NGS PSR2 Safety Factor 14 Report: Radiological Impact on the Environment*, December 2016] Environmental Risk Assessment Report for Pickering Nuclear [P-REP-07010-10012-R000, *Environmental Risk Assessment Report for Pickering Nuclear,* January 2014] CNSC Regulatory Oversight Report for 2015	1, 2, 3, 4, 5

Strength ID	Strength Title and Description	Justification	Level
S-13	**Radiation Exposure Performance** Radiation protection performance exceeds objectives and application of As Low as Reasonably Achievable (ALARA) meets or exceeds regulatory expectations.	Programs and principles are fully developed and effectively implemented. The Safety Factor 9 Report states that "Improvements in radiation exposure performance were realized through the implementation of increased line accountability for the control of radiation exposure, including Departmental Dose Reduction Plans." In addition, the review in the Safety Factor 15 Report has confirmed that Radiation Protection has been adequately accounted for in the design and operation of Pickering NGS, and that Radiation Protection provisions (including design and equipment) provide protection of persons from the harmful effects of radiation and ensure that contamination and radiation exposures and doses to persons are monitored and controlled and maintained ALARA. Assessments of CNSC G-129 and Class I Nuclear Facilities Regulations SOR/2000-203 also confirmed that Pickering NGS conforms with the safety-significant requirements relevant to Radiation Protection. The CNSC Regulatory Oversight Report for Canadian Nuclear Power Plants: 2015 states that OPG continued to implement a highly effective, well documented and mature program, based on industry best practices, to keep doses ALARA at Pickering. Furthermore, the Regulatory Oversight Report for Canadian Nuclear Power Plants: 2015 states that CNSC staff concluded that the "Radiation Protection" and "Operating Performance" Safety and Control Areas at Pickering met or exceeded performance objectives and all applicable regulatory requirements, and rated these Safety and Control Areas as Fully Satisfactory. **Source(s):** Section 4.1.6 of PSR2 Safety Factor 9 Report [P-REP-03680-00013-R000, *Pickering NGS PSR2 Safety Factor 9 Report: Use of Experience from Other Nuclear Power Plants and Research Findings*, October 2016] Section 4.1.4 of PSR2 Safety Factor 15 Report [P-REP-03680-00019-R001,	1, 2, 3, 4

		Pickering NGS PSR2 Safety Factor 15 Report: Radiation Protection, April 2017] CNSC Regulatory Oversight Report for 2015	
S-14	**Heat Removal Systems** Pickering NGS has made modifications to achieve multiple overlapping heat removal provisions for normal operation and design basis events, and for Beyond Design Basis conditions.	In recognition of modern standards and incorporating OPEX from events such as the 2011 Fukushima accident, Pickering has made modifications to achieve multiple, overlapping heat removal systems of adequate capacity. These heat removal systems, together with their support systems, ensure that heat generated in the Fuel is transferred to the atmosphere or the lake under normal operating and shutdown/outage conditions, as well as in response to DBAs and Beyond Design Basis conditions, which is a requirement for new nuclear power plants. These systems are: • Steam Generators (boilers) supplied by inventory from normal or auxiliary feed water or the Pickering 1,4 Emergency Boiler Water System (EBWS) or Pickering 5-8 Emergency Water System (EWS). • Shutdown Cooling Heat Exchangers supplied by normal or Emergency High Pressure Service Water. • Emergency heat removal with High Pressure ECI and ECI recovery, with Reactor Building Air Coolers. • For events involving a loss of Steam Generator inventory, in the short term, the Boiler Emergency Cooling System (BECS) provides water to both Pickering 1,4 and Pickering 5-8 for reactor decay heat removal by the boilers for accident situations initiated by a failure of the normal feedwater supply. For long-term cooling, the EBWS is designed to provide emergency water to the boilers of Pickering 1,4. In Pickering 5-8, the Shutdown Cooling System is initiated manually to provide the heat sink for the Heat Transport System (HTS). In addition, the EWS is a seismically qualified system supplying long-term emergency makeup to the boilers, HTS, ECI recovery	1, 2, 3, 4

Strength ID	Strength Title and Description	Justification	Level
		heat exchangers, Containment air coolers and the Moderator, for Pickering Units 5-8. • For Beyond Design Basis conditions, which are a requirement for new nuclear power plants, Pickering 5-8 units have emergency heat removal available including EWS to the HTS and Emergency Mitigating Equipment water supply to maintain cooling. Pickering Units 1,4 have Firewater supply or Emergency Mitigating Equipment (EME) water supply to maintain fuel cooling. In Pickering 1,4 and Pickering 5-8, EME provides an additional makeup water supply through the use of portable diesel-powered pumps that can provide make-up to the secondary side of the boilers, to the HTS and to the Moderator. **Sources:** Pickering B Safety Report [NK30-SR-01320-00002-R004, *Pickering B Safety Report – Part 2*, October 10, 2012] Pickering A Safety Report [NA44-SR-01320-00001-R016, *Pickering A Safety Report*, July 20, 2017]	
S-15	**Electrical Power System** Pickering NGS has implemented design modifications to provide standby and Emergency Power Systems to provide the necessary electrical power to maintain the plant in a safe shutdown state and ensure nuclear safety in Design Basis Accidents and Beyond Design Basis conditions,	The originally designed Electrical Power System at Pickering NGS has been enhanced through design modifications such that units are equipped with multiple sources of backup electrical power to ensure that controls and equipment important to safe operation are available during normal and abnormal conditions. These are: • Site Electrical System. This distribution system can be used for transferring backup auxiliary power to any of the unit Class IV systems High Pressure ECI pump motors, ECI associated motorized valves for each of the Pickering 1,4 units, and the electrical services of any single unit that is	1, 2, 3, 4, 5

Strength ID	Strength Title and Description	Justification	Level
	and support Severe Accident Management actions.	deprived of supply from its normal sources). • Standby Generators (SG). This power comes from six independent gas turbine driven generators for Pickering Units 1,4 and six for Pickering Units 5-8. The standby power is dedicated to those loads that are required for the safe shutdown of the reactor and heat sink/cooling of the Fuel core. Additionally, the SG1 of each unit pair can be selected to run a High Pressure ECI pump in an islanded mode. • In addition, the Emergency Power System (EPS) for Pickering 5-8 supplies power to a specific portion of the Safety-Related Systems in the station. The purpose of EPS is to independently perform the critical reactor safety functions, i.e., Control, Cool and Contain on total loss of Group 1 distribution systems. Also, provisions for mitigating a complete loss of onsite and offsite AC power are provided. The purpose of this is to address 'Station Blackout'. At Pickering, this is a BDBA involving total loss of all AC power. Station blackout imposes requirements on stored water systems for heatsinks with make-up from water to boilers using the Auxiliary Power System (APS). The APS is a back-up power supply system that supplies power to selected Class IV loads following a total loss of Class IV power across the Pickering NGS following a failure of the Bulk Electrical System. In addition, Emergency Mitigating Equipment (EME) also supports the response in such events. **Sources:** Pickering B Safety Report [NK30-SR-01320-00002-R004, *Pickering B Safety Report – Part 2*, October 10, 2012] Pickering A Safety Report [NA44-SR-01320-00001-R016, *Pickering A Safety Report*, July 20, 2017]	
S-16	**Human Factors Engineering**	Pickering NGS was originally designed to the standards of the day and designers utilized best design practices in addition to incorporation of	1, 2, 3, 4

Strength ID	Strength Title and Description	Justification	Level
	Program A robust human factors engineering program has been established.	operations and maintenance experience (e.g., for Pickering Units 1-4, experience was incorporated from Douglas Point and the Nuclear Power Demonstration plant, while Pickering Units 5-8 incorporated experience from Pickering Units 1-4 and Bruce NGS A). Operating experience (OPEX) and improvements have been incorporated into the processes and design to improve the human-machine interfaces in many areas (e.g., Control Room annunciation upgrades as a result of changes to computer hardware and operator interface). The Modification Process [N-PROC-MP-0090-R014, *Modification Process*, October 14, 2106] includes a requirement for the preparation of a Design Scoping Checklist [N-FORM-10959-R016, *Design Scoping Checklist*, June 27, 2016], which contains a listing of high-level Human Factors Engineering questions that are designed to identify whether the proposed modification has Human Factors Engineering impact. Since 2000, Human Factors Engineering has been explicitly considered for all design changes at Pickering NGS, resulting in continuous improvements to the human-machine interfaces throughout the plant. In terms of design changes to the Main Control Room and other work stations, when required, Human Factors Engineering Program Plans are prepared in accordance with Guide for OPG Human Factors Engineering Process [N-MAN-06700-10002-R004, *Guide for OPG Human Factors Engineering Process,* December 18, 2015], which describes OPG's Human Factors Engineering processes and approach to the conduct of Human Factors Engineering activities and OPG's expectations for performing Human Factors Engineering activities. In order to improve the human machine interface of the Pickering Units 1,4 Digital Control Computer interface, the Pickering A Control Room Enhancement was initiated. This enhancement is part of the Digital Control Computer system and forms an interface between Main Control Room operators and the Digital Control Computers.	

Strength ID	Strength Title and Description	Justification	Level
		The Human Factors Engineering Program Plan prepared by OPG meets the safety-significant requirements of CNSC G-276 and CNSC G-278, as well as meeting the intent of applicable elements from NUREG-0711. These guides and standards are relatively new, and OPG programs have been updated to meet the requirements of these newer standards. These guides are not mandatory requirements in the Licence Conditions Handbook and hence compliance with these guides is considered a Strength. **Source(s):** Section 4.1.5 of PSR2 Safety Factor 1 Report [P-REP-03680-00008-R000, *Pickering NGS PSR2 Safety Factor 1 Report: Plant Design*, March 2017] Sections B.11, B.12, and B.21 of Code and Standard Reviews Associated with Safety Factors 8, 10, 12, 13, and 14 [P-REP-03680-00021-R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 8, 10, 12, 13, and 14*, December 2016]	
S-17	**Environmental Qualification Program** The Environmental Qualification Program at OPG is fully developed.	The program is fully developed, and interfaces with other station procedures are well identified. This program was not part of the original design or licensing basis for Pickering NGS. The review of Safety Factor 3 has confirmed that the required Pickering NGS equipment important to safety has been properly environmentally qualified. Also, Pickering NGS is assessed as part of PSR2 to be in conformance with the safety-significant requirements of CSA N290.13-05, which, although now a mandatory licence document, was not part of the original Pickering NGS design basis. **Source(s):** PSR2 Safety Factor 3 Report [P-REP-03680-00006-R000, *Pickering NGS PSR2 Safety Factor 3 Report: Equipment Qualification (Seismic and*	1, 2, 3

		Environmental), July 2016] Section B.1 of Code and Standard Reviews Associated with Safety Factors 2, 3, and 4 [P-REP-03680-00004-R000, *Pickering NGS Periodic Safety Review 2: Code and Standard Reviews for Safety Factors 2 (Actual Condition of SSCs), 3 (Equipment Qualification) and 4 (Aging),* July 2016]	
S-18	**Comprehensive Set of Performance Indicators** A comprehensive set of station performance indicators is in place to monitor operations.	Within OPG, a tiered approach for performance indicators has been implemented based on industry best practice. OPG Nuclear has implemented a top-down and bottom-up approach to business planning where its leaders establish clear performance targets. The leaders then, in subsequent business plans, identify actions and accountabilities required to achieve these targets over a specified period of time. In accordance with PROL 48.03/2018, REGDOC-3.1.1 (identifies specific performance indicators that must be reported to the CNSC on a quarterly basis. OPG records and reports these in the Quarterly Report on Safety Performance Indicators. These indicators are: 1) Collective Radiation Exposure 2) Personnel Contamination Events 3) Unplanned Dose/Unplanned Exposure 4) Loose Contamination Events 5) Environmental Releases – Radiological 6) Spills 7) Mispositioning Index	1, 2, 3, 4, 5

Strength ID	Strength Title and Description	Justification	Level
		8) Number of Unplanned Transients 9) Reactivity Management Index 10) Unit Capability Factor 11) Unplanned Capability Loss Factor 12) Forced Loss Rate 13) Reactor Trip Rate 14) Corrective Maintenance Backlog 15) Deficient Maintenance Backlog 16) Deferral of Preventive Maintenance 17) Safety System Test Performance 18) Preventive Maintenance Completion Ratio 19) Chemistry Index 20) Chemistry Compliance Index (non-Guaranteed Shutdown State and Guaranteed Shutdown State) 21) Conventional Health and Safety 22) Radiological Emergencies Performance Index 23) Emergency Response Organization Drill Participation Index 24) Emergency Response Resources Completion Index 25) Low- and Intermediate-Level Radioactive Solid Waste Generated OPG monitors performance indicators using the Electronic Performance Reporting system to measure the performance of the plant against the business planning goals and targets. Business Plan targets are set based on	

Strength ID	Strength Title and Description	Justification	Level
		extensive industry benchmarking with the objective of achieving top quartile performance. The Electronic Performance Reporting system standardizes data collection, analysis, and the performance indicator reporting process. It tracks performance measure targets and results in a single repository. Monthly results are rated and colour coded based on performance results versus target. The system allows trending and development of corrective action plans and promotes ownership and accountability of staff in improving performance. Furthermore, the Regulatory Oversight Report for Canadian Nuclear Power Plants: 2015 states that CNSC staff concluded that the “Operating Performance” Safety and Control Area at Pickering met or exceeded performance objectives and all applicable regulatory requirements, and rated this Safety and Control Area as Fully Satisfactory. **Source(s):** Section 4.1.4 and Section 4.1.5 of PSR2 Safety Factor 8 Report [P-REP-03680-00012-R000, *Pickering NGS PSR2 Safety Factor 8 Report: Safety Performance,* December 2016] CNSC Regulatory Oversight Report for 2015	
S-19	**Use of Operating Experience and Research Findings** Rigour in the identification and application of OPEX and of research findings, and support of a senior advisory team for Research & Development issue identification and action implementation.	OPG has established procedures for sending and receiving experience relevant to safety from other nuclear power plants and relevant non-nuclear plants Operating Experience Process [N-PROC-RA-0035 R019*, Operating Experience Process,* September 14, 2016]. A weekly CANDU Owners Group (COG) OPEX screening meeting, facilitated and administered by COG, serves as an initial screening forum to review event reports from CANDU stations, nuclear industry and non-nuclear sources for applicability and significance to CANDU units. Committee members include representatives from all CANDU facilities (including OPG Pickering), vendors, research organizations and WANO.	1, 2, 3, 4, 5

Strength ID	Strength Title and Description	Justification	Level
		The PSR2 has confirmed for Pickering NGS that there is good feedback of relevant experience from other nuclear power plants and from findings of research, and that this is used to introduce reasonable and practicable safety improvements at the plant or in the operating organization. Moreover, research activities are pursued and results are used to enhance nuclear safety and equipment performance and reliability. Pickering NGS shares its programs, procedures, Compliance Reporting and Corrective Action processes as commonly maintained programs with Darlington NGS, and thus observations and lessons learned at Darlington NGS are used at Pickering NGS and vice versa. Furthermore, the PSR2 compliance assessment of regulatory mandated standard CSA N286-12, an element of which is OPEX, confirmed conformance with the safety-significant requirements. **Source(s):** CNSC Correspondence on PSR2 - CNSC Staff Assessment of OPG SFR9, SFR11, and SFR15 [P-CORR-00531-04950, *Pickering NGS: PSR2 - CNSC Staff Assessment of OPG SFR9, SFR11, and SFR15*, January 25, 2017] Section A.1 of Code and Standard Reviews Associated with Safety Factors 9, 11, and 15 [P-REP-03680-0586480-R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 9, 11, and 15*, September 2016]	
S-20	**Minimum Staff Complement Management** An online computer program for monitoring staffing level for minimum complement roles, as well as forecasting future staffing	The use of tools available on the local area network to ensure current and future staffing needs demonstrates maturity of this process. This is supported by compliance with the safety-significant requirements of CNSC G-323, Ensuring the Presence of Sufficient Qualified Staff at Class I Nuclear Facilities – Minimum Staff Complement, which is referenced in the Pickering NGS Licence Conditions Handbook (as guidance.	1, 2, 3, 4

Strength ID	Strength Title and Description	Justification	Level
	needs, thereby ensuring minimum complement coverage, is effectively managed on a continuous basis.	Furthermore, the Regulatory Oversight Report for Canadian Nuclear Power Plants: 2015 states that CNSC staff concluded that the “Operating Performance” Safety and Control Area at Pickering met or exceeded performance objectives and all applicable regulatory requirements, and rated this Safety and Control Area as Fully Satisfactory. **Source(s):** Section 4.1.1 of PSR2 Safety Factor 12 Report [P-REP-03680-00016 R000, *Pickering NGS PSR2 Safety Factor 12 Report: Human Factors,* December 2016] Section B.10 of Code and Standard Reviews Associated with Safety Factors 8, 10, 12, 13, and 14 [P-REP-03680-00021 R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 8, 10, 12, 13, and 14*, December 2016] CNSC Regulatory Oversight Report for 2015	
S-21	**Training** A mature training and certification program is in place that includes a rigorous and comprehensive training program for selecting and training candidates.	According to the compliance assessment of regulatory requirements of REGDOC-2.2.2, Personnel Training, training of personnel is a critical and well-established aspect of the OPG Nuclear program. The discussion of training in the Safety Factor 12 Report expresses the comprehensiveness of the Systematic Approach to Training program. Pickering NGS is compliant with RD-204, Certification of Persons Working at Nuclear Power Plants. The most recent Fleetview Program Health and Performance Report for 2015 [N-REP-08130-0635343 R000, *Fleetview Program Health and Performance Report (Q1/2016 to Q4/2016)*, January 2017] reported with respect to Human Performance and Training that the training program aligned with industry best practices.	1, 2, 3, 4, 5

Strength ID	Strength Title and Description	Justification	Level
		Source(s): Section 4.1.3 of PSR2 Safety Factor 12 Report [P-REP-03680-00016-R000, *Pickering NGS PSR2 Safety Factor 12 Report: Human Factors*, December 2016] Sections B.6 and B.17 of Code and Standard Reviews Associated with Safety Factors 8, 10, 12, 13, and 14 [P-REP-03680-00021-R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 8, 10, 12, 13, and 14,* December 2016]	
S-22	**Emergency Management** A mature emergency response infrastructure is in place, and the requisite qualified manpower and expertise are maintained. As well, a mutual aid emergency support agreement among the Canadian nuclear operators has been established for inter-utility emergency support. Pickering has a well-established Severe Accident Management Program.	OPG has comprehensive operating procedures that apply to normal, abnormal and emergency conditions (including Transients, DBAs, post-accident conditions and BDBAs). Pickering NGS operations staff operates the plant through the use of approved Operating Manuals, Operating Procedures, Alarm Response Manuals and Safety-Related System Tests, and uses these manuals to respond to any abnormal conditions. If it is not possible to address an abnormal condition through the system Operating Manuals and/or Alarm Response Manuals, upon confirmation or diagnosis of emergency conditions, including DBAs, staff respond per the event-based Abnormal Incident Manuals. Emergency Mitigating Equipment Guidelines and Severe Accident Management Guidelines are used to respond to BDBAs, including severe accidents. Severe Accident Management Guidelines are written guidance to implement strategies should a BDBA progress to a severe accident. In addition, Pickering has implemented an Automated Source Term Gamma Monitoring System that meets provincial regulations for timely notification of environmental hazards presented following an event that has the risk of	3, 4, 5

Strength ID	Strength Title and Description	Justification	Level
		disseminating radioactive contamination surrounding the plant. Through the evolution of earlier guides to the present version of REGDOC-2.3.2, Accident Management, OPG has developed and validated an effective suite of procedures and guidance as discussed above. In particular, the guidance for BDBAs, coupled with the advanced installation of Emergency Mitigating Equipment, demonstrates a commitment to fulfilling the requirements of defence-in-depth. Further, given the conformance with the safety-significant requirements of REGDOC-2.3.2, this is a Strength. The PSR2 has confirmed that Pickering NGS has adequate plans, staff, facilities and equipment in place for dealing with emergencies, and that there are adequate arrangements in place for regular emergency training and exercises, and interaction and coordination with local and national authorities. The REGDOC-2.10.1, Nuclear Emergency Preparedness and Response compliance assessment noted that there is a transition plan in place and that findings are already being addressed. REGDOC-2.10.1, a new standard currently not in the Licence Conditions Handbook, includes recommendations made by the CNSC Fukushima Task Force and the External Advisory Committee to strengthen Canadian Licensees' emergency preparedness programs. Also, the PSR2 assessment confirmed that Pickering NGS is in conformance with the safety significant requirements in CSA N1600-2014, General Requirements for Nuclear Emergency Management Programs, which is a new standard. **Source(s):** Section 4.1.11 of PSR2 Safety Factor 13 Report [P-REP-03680-00017-R000, *Pickering NGS PSR2 Safety Factor 13 Report: Emergency Planning*, December 2016] Table 1 in Fukushima Action Item Status Report [N-REP-03600-10003-R007, *Fukushima Action Item Status Report*, November 2015]

		Section B.18 of Code and Standard Reviews Associated with Safety Factors 8, 10, 12, 13, and 14 [P-REP-03680-00021-R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 8, 10, 12, 13, and 14,* December 2016]	
S-23	**Environmental Protection Program** The Environmental Protection Program is robust.	The PSR2 has confirmed that Pickering NGS has an effective program for monitoring the radiological impact of the plant on the environment; the program ensures that emissions are properly controlled and are ALARA. PSR2 assessments against codes and standards show that OPG is compliant with the safety-significant requirements of the following modern codes and standards related to environmental protection, and this is considered a Strength: • CNSC REGDOC-2.9.1, Environmental Protection Policies, Programs and Procedures – supersedes S-296, which is a mandatory standard in the Pickering NGS Licence Conditions Handbook. • CSA N288.1-14, Guidelines for Calculating Derived Release Limits for Radioactive Material in Airborne and Liquid Effluents for Normal Operation of Nuclear Facilities – a mandatory standard in the Pickering NGS Licence Conditions Handbook. • CSA N288.4-10, Environmental Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills – a mandatory standard in the Pickering NGS Licence Conditions Handbook. • CSA N288.5-11, Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills – a mandatory standard in the Pickering NGS Licence Conditions Handbook CSA N288.6-12, Environmental Risk Assessments at Class I Nuclear Facilities and Uranium Mines and Mills – not a mandatory standard in the Pickering NGS Licence Conditions Handbook.	1, 2, 3, 4, 5

Strength ID	Strength Title and Description	Justification	Level
		• CSA N288.7-15, Groundwater Protection Programs at Class I Nuclear Facilities and Uranium Mines and Mills – the standard is not identified in the Pickering NGS Licence Conditions Handbook. In addition, the Environmental Management Systems program at Pickering NGS has been developed and implemented in accordance with the elements of the ISO 14001 Standard, *Environmental Management Systems – Requirements with Guidance for Use*. Also the program is registered under the ISO 14001 Standard, and is therefore required to be continually improved in accordance with this Standard. **Source(s):** Section 4.2, Table 3 of Safety Factor 14 Report [P-REP-03680-00018-R000, *Pickering NGS PSR2 Safety Factor 14 Report: Radiological Impact on the Environment*, December 2016] Code and Standard Reviews Associated with Safety Factors 8, 10, 12, 13, and 14 [P-REP-03680-00021-R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 8, 10, 12, 13, and 14*, December 2016] Code and Standard Reviews Associated with Safety Factors 9, 11, and 15 [P-REP-03680-0586480-R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 9, 11, and 15*, September 2016]	
S-24	**Advanced Technology to Support Radiation Protection** Remotely controlled technology in place to simulate radiation environments and hazards is providing a safe learning	Pickering NGS has implemented technological improvements in support of radiological protection that include: • Use of robotics to perform tasks in radioactive work areas, reducing radiation exposure and therefore dose to workers; • Use of dynamic learning activities to provide workers an opportunity to	1, 2, 3, 4

Strength ID	Strength Title and Description	Justification	Level
	environment for training and practicing radiation protection procedures.	practice radiation protection fundamentals in a simulated radioactive work environment using remotely controlled technology; • Implementation of remote reading radiation detection instrumentation and real time data transmission to facilitate improved job planning and awareness of current radiological conditions; and • Implementation of a gamma ray imaging spectrometer to perform enhanced radiation surveys, to identify areas with elevated dose rates, enabling more effective shielding to reduce dose to workers. The Regulatory Oversight Report for Canadian Nuclear Power Plants: 2015 states that OPG continued to implement a highly effective, well documented and mature program, based on industry best practices, to keep doses ALARA at Pickering. **Source(s):** PSR2 Safety Factor 15 Report [P-REP-03680-00019-R001, *Pickering NGS PSR2 Safety Factor 15 Report: Radiation Protection*, April 2017] CNSC Regulatory Oversight Report for 2015	

Appendix F – Proposed Global Issue Resolution Statement Summaries

Resolution Statement #	Resolution Statement Summary	Defence-in-Depth Level
GI-1-RS1	Complete CSA N285.8 Compliance Plan activities, including responding to comments.	1,2,3
GI-1-RS2	Review and revise if/as required the CSA N285.4 compliant Periodic Inspection Plans for Fuel Channels for Pickering NGS to cover the extended operating period.	1,2,3
GI-1-RS3	Update the Fuel Channels Life Cycle Management Plan for Pickering 1,4 for the extended operating period.	1,2,3
GI-1-RS4	Update the structure of the Fuel Channels LCMP.	1,2,3
GI-2-RS1	Update the Feeders Life Cycle Management Plan for Pickering 1,4 for the extended operating period based on updated fitness-for-service assessment.	1,2,3
GI-3-RS1	Update the Steam Generators Life Cycle Management Plan for Pickering 1,4 for the extended operating period based on updated fitness-for-service assessment.	1,2,3
GI-4-RS1	Update the Reactor Components and Structures Life Cycle Management Plan for Pickering 1,4 for the extended operating period based on updated fitness-for-service assessment.	1,2,3
GI-4-RS2	Perform measurements of Calandria Tube/Liquid Injection Shutdown System nozzle gaps on Units 5-8 to refine the gap closure rates. Using this new measurement data, update analyses as required, to demonstrate Fitness for Service.	1,2,3
GI-5-RS1	Confirm the adequacy of the service limits assessments for Nuclear Class 1 piping (excluding Major Components) after accounting for impact of environmental factors.	1,2,3

Resolution Statement #	Resolution Statement Summary	Defence-in-Depth Level
GI-6-RS1	Reassess the impact of the changes in the cable criticality coding and update the scope of the cable surveillance plan.	1, 2, 3, 4
GI-7-RS1	Update the buried piping program asset management plan and risk ranking for the extended operating period.	3, 4
GI-7-RS2	Update governance to reflect a graded approach in the event that leakage in fuel oil piping occurs.	1
GI-8-RS1	Complete and update Condition Assessments for the piping systems and commodity groups in PSR2 scope for station operation for the extended operating period.	1, 2, 3
GI-8-RS2	Develop and implement a process to track and report aging-management-related actions from the Condition Assessment recommendations.	1
GI-9-RS1	Complete the required assessment to support the current fuel basket stacking arrangements in the Pickering NGS IFBs.	1
GI-10-RS1	Complete the Pickering 5-8 IFB Leakage Mitigation Project to mitigate leaks from IFB-B to the interspace.	1
GI-12-RS1	Complete EQ Assessment re-assessments to support the extended operating period.	3
GI-19-RS1	Demonstrate the fitness for service of the foundation steel H-piles for the Pickering A Reactor Building, Vacuum Building and Pressure Relief Duct at the Pickering site for the extended operating period.	1, 2, 3, 4
GI-24-RS1	Update Heat Transport System aging safety analysis models and perform the required safety analysis of events most impacted by aging (small-break LOCA, loss of flow and neutron overpower) to support extended operation.	2, 3
GI-25-RS1	Complete the re-categorization of the large-break LOCA CANDU Safety Issues to Category 2.	3

Resolution Statement #	Resolution Statement Summary	Defence-in-Depth Level
GI-25-RS2	Complete the re-categorization of CANDU Safety Issue CSI-IH6 for Pickering to Category 2. (Pickering 1,4 high-energy piping)	3
GI-26-RS1	Complete the emergency response projection enhancements identified in Action Item 2016-OPG-7469: Implementation of Emergency Response Projection Computer Code Upgrades.	5
GI-27-RS1	Complete actions from PSA improvement plan.	3, 4
GI-27-RS2	Investigate and implement additional practicable design, operational and/or analytical enhancements to further improve Pickering 1,4 Severe Core Damage Frequency and Large Release Frequency.	4
GI-31-RS1	Complete the Pickering NGS Implementation Plan for CNSC REGDOC-2.4.1.	2, 3
GI-31-RS2	Prepare Implementation Plan update for CNSC REGDOC-2.4.1, including consideration of the impact of the extended operating period.	2, 3
GI-32-RS1	Complete the activities in the CNSC REGDOC-2.4.2 Implementation Strategy and update the Strategy in the context of the extended operating period.	2, 3
GI-40-RS1	Ensure the completion of Emergency Mitigating Equipment Phase 2 activities.	3, 4
GI-43-RS1	Perform the scope of inspections for non-Containment safety-significant civil structures as per the established preventive maintenance program (PM 00121151).	1, 2, 3
GI-43-RS2	Develop program governance using a risk-based approach for aging management of safety-significant civil structures for the extended operating period. This applies to non-Containment safety-related civil structures.	1, 2, 3
GI-43-RS3	Prepare Condition Assessments as appropriate for safety-significant civil structures for the extended operating period. Recommendations from these Condition Assessments will be tracked and reported along with those related to GI-8. This applies to non-Containment safety-related civil structures.	1, 2, 3

Resolution Statement #	Resolution Statement Summary	Defence-in-Depth Level
GI-47-RS1	Complete installation of locks on the 058 Yard Fire Protection System.	2, 3
GI-48-RS1	Provide, as necessary, design and/or operational changes and commissioning/testing to facilitate required interconnection of Pickering 1,4 and Pickering 5-8 Fire Protection System water supplies to meet the safety intent of CSA N293-12 Clause 7.3.2.2 (d).	2, 3
GI-50-RS1	Revise the N285.4 PIPs and governance to align with elements of N285.4-14	1, 2, 3
GI-50-RS2	Assess the impact of extended operation on concessions against CSA N285.4	1

Appendix G – Grouping of PSR1 Acceptable Deviations

This appendix groups related and similar Acceptable Deviations (ADs) from PSR1 that have been identified as also being ADs for the extended operation period [P-CORR-03680-0620816-R000, *Re: PSR1 Acceptable Deviations Reassessed for Pickering PSR2*, March 31, 2017] for impact on PSR2. Acceptable Deviations grouped in this appendix are assessed using a combination of common cause and safety principles to determine which engineered and/or administrative safety-related barriers could potentially be impacted. The barriers considered are SSCs or programs that were specifically designed to minimize the likelihood and/or minimize the consequences of events. The PSR1 AD groups in this appendix are carried forward to the assessment in Appendix H.

PSR1 ADs that are assessed to not have an impact, such as legacy or minor document revisions, are grouped in this appendix under PSR1-AD-DOC and are not assessed for aggregate effects in Appendix H as their aggregate impact is deemed not significant.

PSR1 ADs that have been addressed or are not applicable to Pickering NGS are grouped in PSR1-AD-NFA (No Further Action) in this appendix and are not assessed further for aggregate effect in Appendix H.

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
46	CSA N289.2-M81 (R2003) PB ISR Review, General	PSR1-AD1	**Seismic Qualification of SSCs - Gaps against N289 Requirements** These PSR1 ADs involve issues relating to assessing seismicity at the Pickering NGS. These ADs are related to accounting for soil-structure interaction effects including those due to differences between modelling techniques and analysis approaches for the evaluation of site response analysis for the free-field case and complete interaction versus substructure technique for soil/foundation/structure systems. However, the Seismic PSAs [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014] confirm that the Pickering NGS structures meet the intent of the clause.

185	CSA N290.4-M82 PARTS Review, Clause 4.1, "Specific Requirements"		
275	CNSC R-9 PARTS, Clause 3.5.2, "Independence From Process Systems"	PSR1-AD6	**CSA N290.2 – Requirements for Emergency Core Cooling Systems** These ADs involve requirements for independence and redundancy in the design of the Emergency Core Cooling System. The issues associated with these ADs are specific to Pickering Units 1,4. The Pickering 1,4 ECI System utilizes the Moderator System in its low pressure mode, and a number of singletons existed in the design of the ECI System. The issues were assessed as ADs based on the improvements made to the design to reduce the commonality between the Moderator System and ECI recovery, and to address some of the singletons. These design changes provided the greatest benefit. The ADs are associated with Safety Principle D-207, Emergency Heat Removal.
276	CNSC R-9 PARTS, Clause 3.4.3, "Redundancy"		
25	CSA N287.7-96 (R2005) PB ISR Review: Clause 4.1.5, "General Requirements"	PSR1-AD7	**CSA N287.5 and N287.7 – Examination and Testing Requirements for Design of Concrete Containment Structures** These PSR1 ADs involve requirements for Containment capability in response to accidents. Clause 3.4.2 of R-7 identifies that the negative design pressure of Containment must not be greater than that predicted in the Safety Report for a set of postulated events with failure of dousing. It was not
141	N287.5-93 DNGS ISR Review, Issue D010, "Changes to Examination and Testing Requirements for Concrete Containment Structures"		

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
177	CNSC R-7 PARTS Review, Clause 5.1.1, “Pressure Proof Tests”		considered necessary to evaluate event combinations involving failure of dousing for negative Containment design pressure impacts, because these event combinations result in higher rather than lower Containment pressure. These ADs are associated with Safety Principle D-217, Confinement of Radioactive Material.
168	CNSC R-7 PB ISR Review, Clause 3.4.2, “Structural Integrity”		
176	CNSC R-7 PARTS Review, Clause 3.10.3, “Containment Atmosphere Control”	PSR1-AD8	**Requirements for Containment System Leakage Performance** These PSR1 ADs are related to Containment leakage testing. A positive pressure proof test was performed for Pickering NGS A, but a negative pressure test was not performed during commissioning. These ADs are associated with Safety Principle D-217, Confinement of Radioactive Material.
178	CNSC R-7 PARTS Review, Clause 2 of Appendix A, “Isolation”		
179	CNSC R-7 DNGS ISR Review, Issue D015, “Requirements for Penetrations of the Containment Structure”		
181	CSA N290.3-11 DNGS ISR Review, Issue D613, “Containment Boundary Leakage”		
182	CSA N290.3-11 DNGS ISR Review, Issue D607, “Severe Accident and Beyond Design Basis Accident (BDBA) Design/SAMG)”, Gap 02294 only	PSR1-AD9	**N290.3 - Hydrogen Monitoring Requirements** This PSR1 AD involves hydrogen monitoring requirements related to severe accidents. Clause 10.2.3 of N290.3-11 states: “New builds shall monitor the conditions identified according to the requirements of Clause 10.2.2 [... (e.g., pressure, temperature, and hydrogen concentration inside Containment) that need to be monitored for BDBAs ...]”. The absence of hydrogen monitoring instrumentation is acceptable, given installed hydrogen mitigation equipment together with SAMGs provide means to safely manage any hydrogen in Containment. This AD is associated with Safety Principle D-221, Protection of Confinement Structure.

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
187	CSA N290.4-M82 PARTS Review, Clause 4.3.6.1, “Flux Distribution”	PSR1-AD10	**N290.4 - Requirements for Reactor Regulating System (RRS)** These PSR1 ADs involve requirements for RRS related to Start-Up Instrumentation. These issues were identified during the PARTS review and are related to the requirement for the operator to initiate monitoring of the flux tilt and initiate power reduction as needed. Collectively, these ADs are associated with Safety Principle D-205, Startup, Shutdown and Low Power Operation, and D-230 Preservation of Control Capability.
191	CSA N290.5-M90 PARTS Review, Clause 5.4.4.2, "Number of Rectifiers"	PSR1-AD11	**N290.5 - Requirements for Electrical Power and Instrument Air Systems** These ADs involve reliability requirements for the power and other support systems design. Per Regulatory Document RD-98, reliability targets are set for Systems Important to Safety. The Systems Important to Safety are monitored to meet their reliability target. Since the reliability of each system has been demonstrated to be acceptable with its current design, the Acceptable Deviation remains applicable. These ADs are associated with Safety Principle D-174, Reliability Targets.
192	CSA N290.6-M82 PB ISR Review, Clause 5.7.1, "Maintenance and Calibration Capability"	PSR1-AD12	**N290.6 - Requirements for Post-Accident Monitoring** These PSR1 ADs involve requirements for post-accident monitoring design. Gaps were identified on the basis that should a component in the post-accident monitoring system fail, it may not be immediately repairable, and there may not be capability to perform post-accident calibration, depending on the component’s location and the accident scenario. These gaps were assessed to be ADs based on the sufficiency of instrument loops that would be accessible post-accident, because there is sufficient redundancy, and because calibrations during
193	CSA N290.6-M82 PB ISR Review, Clause 5.7.3, "Maintenance and Calibration Capability"		
194	CSA N290.6-M82 PB ISR Review, Clause 5.12.1, "Standards for		

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
	Mechanical and Pressure-Retaining Piping Components"		post-accident mission are not required. Also, regarding (AD #194), instrument tubes coming out of Feeder cabinets have less than 18” separation. However, the instrument tubes are protected by barriers where the separation is less than 18" [DGS-30-68000-002, *Design Guide Supplement, GP1 Inst Tubing Separation in F/M VAULT/5/63335/63720*, February 1980], and therefore, this issue is assessed as an AD in Pickering B ISR. These ADs are associated with AM-326 Engineered Features of Accident Management.
196	CSA N291-08 DNGS ISR Review: Issue D283, "Design Requirements for Steel Safety-Related Structures"	PSR1-AD13	**N291-08 - Safety-Related Structures (Non-Containment) for Nuclear Power Plants** These PSR1 ADs involve requirements for Non-Containment Safety-Related Structures from CSA N291-08. The ADs relate to issues that design documents are not fully consistent with requirements listed in CAN/CSA-N291-08. In PSR2, these issues are assessed to be ADs based on the fact that safety-related structures were designed and analyzed in accordance with the applicable standards at the time, which meet the intent of N291-08. These ADs are associated with D-150 Design Management.

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
229	IAEA NS-R-1 PB ISR Review, Clause 5.34, "Single Failure Criterion"	PSR1-AD15	**IAEA NS-R-1 and CNSC RD-337 Single Failure Criterion** These PSR1 ADs involve safety-related requirements for application of the Single Failure Criterion in plant design. This AD group relates to issues that were raised against IAEA NS-R-1 and CNSC RD-337 and assessed as ADs. REGDOC-2.5.2, which adopts principles from NS-R-1 and supersedes CNSC RD-337, was reviewed in PSR2, including a detailed assessment of PSR1 ADs. The PSR2 review confirmed that the dispositions provided for Pickering 5-8 during the Pickering NGS B ISR remain valid and are also applicable to Pickering 1,4, and as a result, a new PSR2 Gap was not raised for these ADs. These ADs are all associated with Safety Principle D-150, Design Management, and M&C-246 Safety Evaluation of Design.
230	IAEA NS-R-1 PB ISR Review, Clause 5.35, "Single Failure Criterion"		
231	IAEA NS-R-1 PB ISR Review, Clause 5.37, "Single Failure Criterion"		
232	IAEA NS-R-1 PB ISR Review, Clause 5.38, "Single Failure Criterion"		
233	IAEA NS-R-1 PB ISR Review, Clause 5.41, "Auxiliary Services"		
240	CNSC RD-337 DNGS ISR Review: Issue D072, "Single Failure Criterion"		
180	CSA N290.3-11 DNGS ISR Review, Issue D611, "Coatings and Coverings Within Containment Systems"	PSR1-AD16	**Requirements for Containment Coatings and Coverings** These PSR1 ADs involve safety-related requirements for plant design. The ADs included in this group concern non-metallic coatings and liners that perform a safety function, such as preserving the concrete Containment envelope. The basic requirement is that not only should these materials be carefully selected and applied, but their deterioration (especially under post-accident conditions) should not impair the performance of other safety functions, such as flow through ECI strainers. The ECI System recovery strainer design considers potential materials that could result in a pressure drop across the strainers and affect pump
235	IAEA NS-R-1 PB ISR Review, Clause 6.67, "Coverings and Coatings"		
239	CNSC RD-337 DNGS ISR Review: Issue D071, "Coatings and Coverings Within Containment System"		

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
195	CSA N291-08 DNGS ISR Review: Issue D071, "Coatings and Coverings Within Containment System"		operation. As a result, a new PSR2 Gap was not raised for these ADs. These ADs are all associated with Safety Principle D-182, Equipment Qualification, and D-207 Emergency Heat Removal, and therefore they are grouped together.
237	IAEA NS-R-1 PB ISR Review, Clause 6.100, "Radiation Protection"	PSR1-AD17	**IAEA Requirements for Radiation Protection** This PSR1 AD involves requirements for radiation protection. Consideration of the buildup of radiation levels with time in areas of personnel occupancy is required in the design of the plant and in housekeeping practices during the conduct of operating and maintenance activities. Although the specific requirements and design documentation may not be fully consistent with the requirements of IAEA NS-R-1, good engineering practice was followed during the initial design of the station such that the layout and operation of facility SSCs, and processes are consistent with the established guidelines and contribute to maintaining occupational radiation exposures ALARA. An important principle of the Radiation Protection program is the control of exposures. This AD is associated with Safety Principle D-188, Radiation Protection in Design.
243	CNSC RD-337 DNGS ISR Review: Issue D278, "Turbine Orientation"	PSR1-AD18	**CNSC Requirements for Hazards** This PSR1 AD involves safety-related requirements for hazards. While the orientation of the turbine generators does not comply with the requirement of CNSC RD-337, the effect of turbine missiles has been considered in the supporting design analysis. This AD is associated with Safety Principle D-177, Dependent Failures.
236	IAEA NS-R-1 PB ISR Review, Clause 6.9, "Fuel Elements and Assemblies"	PSR1-AD19	**Deterministic Safety Analysis** These PSR1 ADs involve deterministic safety analysis requirements.

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
246	CNSC G-144 PB ISR Review, Clause 4.1, "Potential Consequences"		The PSR2 review of CNSC G-144, CNSC R-77 and CSA N288.2 confirmed that the dispositions provided for Pickering 5-8 during the Pickering NGS B ISR are also applicable to Pickering 1,4, and as a result, a PSR2 Gap was not raised for these ADs. These ADs are associated with Safety Principle D-150, Design Management, and M&C-246, Safety Evaluation of Design.

263	NBCC 2005 DNGS ISR Review, Issue D450, "Building Height Determination and Fire Resistance"	PSR1-AD21	**Fire-Related Requirements of NBCC** These ADs arose from the Darlington ISR and involve measures to prevent the spread of fire as well as to ensure staff safety and capability to respond. The scope of this group includes deviations between the existing design of the Darlington NGS and requirements of the NBCC – 2005. For example, Clause 2.1.3.8 is a new Article in NBCC-2005 which calls for integrated testing of fire protection and life safety systems to ensure that they will operate together, as intended. However, documentation could not be found to confirm that integrated systems testing is
264	NBCC 2010 DNGS ISR Review, Issue D519, "Fire Protection and Life Safety System Commissioning"		
265	NBCC 2010 DNGS ISR Review, Issue D524, "Fire and Smoke Characteristics of Electrical Wires and Cables"		

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
266	NBCC 2010 DNGS ISR Review, Issue D525, "Elevator Requirements"		performed for the life safety and fire protection systems installed at Darlington NGS. The PSR2 assessment of these ADs confirms that the rationale for these gaps being classified as ADs at Darlington NGS is also generally applicable to Pickering NGS, based on: • Fire Hazard Analysis and the Fire Safe Shutdown Analysis demonstrate that the safety objectives of the Station can be met under postulated fire scenarios. These analyses have also been completed for Pickering 1,4 and 5-8. • In the event of a fire at the Station, personnel, as per training and as instructed via the public address system, are to avoid the incident unit and area as well as to refrain from using the elevators. This also applies to Pickering NGS. • Access to the Station is limited to trained personnel who are familiar with the hazards and safety features of site buildings. Multiple means of egress are available and existing signage is clearly recognizable and understood by the personnel accessing the Station buildings. This also applies to Pickering NGS. • With respect to electrical conductors, there are no high-rise buildings, areas of refuge, or contained use areas located at Darlington NGS. This also applies to Pickering NGS. These ADs are associated with Safety Principle D-177, Dependent Failures, and are therefore grouped together.

228	IAEA NS-R-1 PB ISR Review, Clause 5.31, "Severe Accidents"	PSR1-AD22	**Software Verification and Validation** These ADs are related to requirements for development, verification and review of computer programs used for Safety Analysis, as well as requirements for software validation. OPG governance establishes a quality assurance program that is robust and compliant, and thus ensures the development of Scientific, Engineering and Safety Analysis software is aligned with the requirements of CNSC G-149 and CAN/CSA- N286.7-99. OPG has
251	CNSC G-149 DNGS ISR Review: Issue D146, "Specifications for Developing Computer Programs not Given in Software QA"		

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
			been participating in an industry-wide COG program addressing software validation. Therefore, this issue continues to be assessed as an AD. These ADs are associated with Safety Principles M&C-246, Safety Evaluation of Design, and M&C-249, Achievement of Quality.

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
The ADs listed below are administrative issues generally related to legacy documents or minor differences between OPG governance and code requirements. They have been assessed to have no significant safety impact, individually or in aggregate.			
1	CSA N290.13-05, PB ISR Review: Clause 5.2.1, "General"	PSR1-AD-DOC1	These PSR1 ADs involve CSA N290.13-05 requirements for qualification test plans, whose intent is met by N-PROC-RA-0044, *Environmental Qualification Assessment*. The Pickering NGS B ISR raised a Gap on the basis that the existing EQ documentation did not include a specific requirement for a qualification test plan and that it be accepted before starting the qualification process. However, it was noted that even with this Gap in the governance, all test reports were first passed through a QA check for suitability as design input documents before being used in EQ Assessments. These items do not impact any specific barriers, or objectives of any of the safety principles for operation during extended period and therefore, are not carried forward for Aggregation. These ADs do not affect the qualification of the equipment because the test reports are required to go through a QA check.
2	CSA N290.13-05, PB ISR Review: Clause 5.2.3, "Qualification Plan"		
12	CSA N285.5-M90, PB ISR Review: Clause 4.1.2 (a), "Responsibility"	PSR1-AD-DOC2	These PSR1 ADs involve high-level requirements for periodic inspection. These ADs identify administrative issues in OPG governance related to N285.5-M90. For example, statements in OPG governance use SHOULD instead of SHALL as specified in the standard. For these cases, all requirements in the standard must be performed unless an exception is granted by the CNSC. Based on this, the use of SHOULD is overridden by the use of SHALL in the PIPs, which have both been submitted to the CNSC for approval. These ADs do not impact any specific barriers, or objectives of any of

14	CSA N285.5-M90, PB ISR Review: Clause 5.3 (b), "Procedures"		
15	CSA N285.5-M90, PB ISR Review: Clauses 6.1.2.1 through 6.1.2.5, "Duties"		

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
16	CSA N285.5-M90, PB ISR Review: Clause 7.1.1, "Inaugural Inspection"		the safety principles for extended operation and therefore, are not carried forward for aggregation.
17	CSA N285.5-M90, PB ISR Review: Clause 8.6.1, "Inspection Interval"		
23	CSA N285.5-M90, PB ISR Review: Clause 8.6.5, "Inspection Interval"		
24	CSA N285.5-M90, PB ISR Review: Clause 8.6.6, "Inspection Interval"		
70	CSA N285.0-06 PB ISR Review, Clause 5.2.8, "Adjoining Systems or Sections"	PSR1-AD-DOC3	These PSR1 ADs involve issues relating to registration and classification of legacy pressure-retaining components. As discussed in the PSR2 N285.0-12 review, [P-REP-03680-00029-R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 1, 5, 6 and 7*, March 2017] the completed configuration management restoration project established the documentation that is required to safely operate and maintain the station. Therefore, this AD is of very low safety significance. These ADs do not impact any specific barriers, or objectives of any of the safety principles for extended operation and therefore, are not carried forward for aggregation.
71	CSA N285.0-06 PB ISR Review, Clause 6.1.1.3, "Designs to be Registered, General Requirements"		
72	CSA N285.0-06 PB ISR Review, Clause 6.1.4, "Supports"		
73	CSA N285.0-06 PB ISR Review, Clause 7.6.2.4, "Supports for Class 1, 2, and 3 Systems and Class 1C, 2C, 3C and 4 Items, Specific Requirements"		
75	CSA N285.0-06 PB ISR Review, Clause 12.1, "Documentation, General"

144	N290.1-M80 PB ISR Review, Clause 4.4.1.3, "Reliability"	PSR1-AD-DOC4	These ADs are related to documentation of detailed design and requirements for reliability and redundancy in the design of the Shutdown Systems. There are no safety impacts associated with the ADs since the reliability requirements are demonstrated by performing unavailability calculations for the Pickering 1,4 and Pickering 5-8 Shutdown Systems per the regulatory requirements in RD-98. These ADs do not impact objectives of any of the safety principles for extended operation and therefore, are not carried forward for aggregation.
145	N290.1-M80 PB ISR Review, Clause 4.4.1.4, "Reliability"		
146	N290.1-M80 PB ISR Review, Clause 4.4.1.5, "Reliability"

163	N290.1-M80 PARTS Review, Clause 5.1, "Quality Assurance Program"		
172	CNSC R-7 PB ISR Review, Clause 3.13.1, "Codes and Standards"	PSR1-AD-DOC5	This PSR1 AD is associated with the requirement to obtain CNSC approval of “any aspects of the design which fail to comply with the applicable requirements of CSA N287 and CAN3-N285.0” during construction. This AD does not impact any specific barriers or objectives of any of the safety principles for extended operation and therefore, is not carried forward for aggregation.
190	CSA N290.5-M90 PB ISR Review, Clause 2, "Reference Publications"	PSR1-AD-DOC6	This PSR1 AD relates to Clause 2 of the standard, which lists applicable references. The references only affect the support power system design if they appear in a clause stating a requirement. Discussions on the applicability and assessment of the reference publications on the support power system design are documented in the compliance evaluations for clauses where the publications are referenced. This AD does not impact any specific barriers or objectives of any of the safety principles for extended operation and therefore, is not carried forward for aggregation.

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
227	IAEA NS-R-1 PB ISR Review, Clause 3.8, "Proven Engineering Practices"	PSR1-AD-DOC7	This PSR1 AD relates to the requirement to specify the process used in the selection of equipment, which some of the original design documents did not. However, OPG standard design practice ensures that equipment that supports a safety function is carefully selected for its functional reliability with due account taken of its probable failure modes. The practice is considered effective. This AD does not impact any specific barriers or objectives of any of the safety principles for extended operation and therefore, is not carried forward for aggregation.

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
The following ADs have either been addressed or are not applicable to Pickering NGS. They are deemed to have no significant aggregate impact.			
3	CSA N285.4-05, PB ISR Review: Clause 3.7.1, "Access for Inspection"	PSR1-AD-NFA1	These PSR1 ADs are assessed in [P-CORR-03680-0620816-R000, *Re: PSR1 Acceptable Deviations Reassessed for Pickering PSR2*, March 31, 2017] as no longer applicable because Pickering NGS is now in compliance with N285.4-05. They are retained for completeness, but are not carried further in the AD aggregation.
4	CSA N285.4-05, PB ISR Review: Clause 7.4.2.2 (f), "Supports"

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
67	CNSC SOR/2000-203 (May 2000) PB ISR Review, Clause 20 (1)(a), "Labelling of Containers and Devices"	PSR1-AD-NFA4	These PSR1 ADs involve issues relating to radiation protection identified by CNSC. All actions to track the regulatory commitments associated with these ADs have been completed [P-CORR-03680-0620816-R000, *Re: PSR1 Acceptable Deviations Reassessed for Pickering PSR2*, March 31, 2017]. These ADs are retained for completeness and are not carried forward for the aggregation assessment.
68	CNSC SOR/2000-203 (May 2000) PB ISR Review, Clause 21 (1), "Posting of Signs at Boundaries and Points of Access"		
69	CNSC SOR/2000-203 (May 2000) Darlington ISR Review, Issue D157, "Labelling and Posting of Radiation Hazard"		
74	CSA N285.0-06 PB ISR Review, Clause 7.7.2.3, "Heat Transport System"	PSR1-AD-NFA5	Clause 7.7.2.3 of CSA N285.0-06 identifies considerations for the qualification of the Heat Transport System for overpressure events. In the updated version of the standard, N285.0-12, the equivalent Clause 7.6.2.3 (c) has been modified to provide relaxation consistent with Regulatory Document R-77, so there is no longer a gap associated with this clause. This AD is retained for completeness and is not carried forward for the aggregation assessment.
79	CSA N285.0-06 PB ISR Review, Clauses 14.5.3, 14.5.3.1, and 14.5.3.2, "Reconciliation Statements for Modifications"	PSR1-AD-NFA6	This AD relates to the backlog of reconciliation statements for Pickering NGS B. This issue has since been closed [NK30-CORR-00531-06815-R000, *Pickering Units 5 to 8: System Registration Update Recovery Plan Project, Action Item 2014-8-16 (RIB #2408)*, May 6, 2014]. Related ADs against Clauses 14.5.3 and 14.5.3.2, were addressed with the same disposition as for Clause 14.5.3.1. Further, this AD is not impacted by operation beyond 2020. This AD is retained for completeness and is not carried forward for the aggregation assessment.

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
83	CSA N293-05 PB ISR Review, Clause 2.1, "Reference Publications"	PSR1-AD-NFA7	These ADs are related to legacy design and construction activities for which, in some cases, documented evidence is not found to confirm compliance with modern codes and standards. Also, there are ADs in this group related to the original design of the Fire Water System in Pickering NGS. Several of these clauses are related to the use of High Pressure Service Water (HPSW) for firewater at Pickering 1,4, which has since been replaced by diesel firewater pumps. The dispositions to these clauses [P-CORR-03680-0620816-R000, *Re: PSR1 Acceptable Deviations Reassessed for Pickering PSR2*, March 31, 2017] also reference the Fire Hazard Assessment and Fire Safe Shutdown Analysis that had been performed. The PSR1 review further stated that, as part of the PARTS Fire Protection Project at the time, Pickering A had committed to installing upgraded fire detection and suppressions systems. These activities have been completed. These ADs are retained for completeness and are not carried forward for the aggregation assessment.
84	CSA N293-05 PB ISR Review, Clause 5.2.2 (d), "Buildings"		
85	CSA N293-05 PB ISR Review, Clause 5.2.4 (a), "Electrical Equipment"

87	CSA N293-05 PB ISR Review, Clause 7.2.1.4, "Penetration Seals"		
88	CSA N293-05 PB ISR Review, Clause 7.2.2.4, "Separation Within Safety Groups"		
89	CSA N293-05 PARTS Review, Clause 6.4.5, "Fire Pumps"		
90	CSA N293-05 PARTS Review, Clause 6.4.7, "Fire Water Used for Other Purposes"		
91	CSA N293-05 PARTS Review, Clause 7.2.2.2, "Separation Between Safety Groups"		
92	CSA N293-05 PARTS Review, Clause 7.2.2.3, "Separating Safety Systems from Fire Hazards"		

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
93	CSA N293-05 PARTS Review, Clause 7.2.2.4, "Separation Within Safety Groups"		
94	CSA N293-05 PARTS Review, Clause 7.2.3.2, "Separation of the Turbine Building"		
143	N290.1-M80 PB ISR Review, Clause 4.4.1.2, "Reliability"	PSR1-AD-NFA8	Clause 4.4.1.2 in N290.1-M80 identifies a requirement that during the design phase, a target unavailability of $1x10^{-4}$/r-yr be used. This is no longer a requirement in N290.1-13. This AD is retained for completeness and is not carried forward for the aggregation assessment.
159	N290.1-M80 PARTS Review, Clause 4.4.9.2, "Testing"	PSR1-AD-NFA9	These ADs involve requirements for on-line testing of the Shutdown Systems components. The updated version of N290.1-13 does not contain the requirement that response times be measured on-line, so both Pickering 1,4 and Pickering 5-8 Shutdown Systems comply with the requirements and, therefore, this is not a PSR2 Gap, and therefore these ADs are not carried forward for aggregation assessment. Also, with respect to AD #165, requirement for diversity, this clause is no longer contained in
160	N290.1-M80 PARTS Review, Clause 4.4.9.6, "Testing"		

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
165	CSA N290.1-80 DNGS ISR Review, Issue D060, "Shutdown System Diversity"		N290.1-13.
169	CNSC R-7 PB ISR Review, Clause 3.8.3, "Separation and Independence Requirements"	PSR1-AD-NFA10	These PSR1 ADs involve separation and independence requirements for Containment. They are associated with Safety Principle D-217, Confinement of Radioactive Material. As documented in [P-CORR-03680-0620816-R000, *Re: PSR1 Acceptable Deviations Reassessed for Pickering PSR2*, March 31, 2017] there is no Gap relating to this issue in PSR2, but it is retained for completeness.
170	CNSC R-7 PB ISR Review, Clause 3.8.4, "Separation and Independence Requirements"		
171	CNSC R-7 PB ISR Review, Clause 3.11.2, "Shielding Requirements"	PSR1-AD-NFA11	This PSR1 AD involves the requirement that shielding assessments be referenced in the Containment design documentation. This issue is a documentation issue only and is not safety significant. The PSR2 assessment is that Clause 11.1 in the updated N290.3-11 requires adequate shielding provisions be present, but does not contain a requirement for the information to be referenced in the design documentation, and therefore this is not considered a PSR2 Gap, but it is retained for completeness.
173	CNSC R-7 PB ISR Review, Clause 3.13.2, "Codes and Standards"	PSR1-AD-NFA12	Clause 3.13.2 of R-7 requires that a list of codes and standards to be applied to the Containment system be prepared and approved by the CNSC prior to construction approval. Codes and standards applicable to Containment are referenced in the design documentation; however,

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
			there is no longer an explicit requirement for regulatory approval in the standard. This gap is no longer applicable to Pickering NGS, and is retained for completeness.
175	CNSC R-7 PARTS Review, Clause 3.7.1, "Availability Requirements"	PSR1-AD-NFA13	This PSR1 AD #175 involves availability requirements for Containment. AD #175 is no longer applicable [P-CORR-03680-0620816-R000, *Re: PSR1 Acceptable Deviations Reassessed for Pickering PSR2*, March 31, 2017], but it is retained for completeness under the PSR1-AD-NFA group.
166	CNSC R-9 PB ISR Review, Clause 3.4.9, "Availability Requirements"	PSR1-AD-NFA14	Clause 3.4.9 of CNSC R-9: The gap was raised due to a documentation discrepancy related to the ECI Heat Transport low pressure signal setpoint between the Design Requirements and the OSR. The gap has since been addressed by revising the Design Requirements documentation.
183	CSA N290.4-M82 PB ISR Review, Clause 4.3.11, "Reactor Start-Up"	PSR1-AD-NFA15	Clause 4.3.11 of N290.4-M82 requires that if special equipment is used for reactor start-up after long periods of shutdown, then that equipment may also have requirements imposed on it by N290.1. Related clauses 5.7 and 5.10.1 in N290.4-11 do not contain the requirement for Start-up Instrumentation to meet these requirements. Therefore, this is not a gap but is retained for completeness.
184	CSA N290.4-M82 PB ISR Review, Clause 6.2.1, "Functional and Performance Requirements"	PSR1-AD-NFA16	Clause 6.2.1 of N290.4-M82 requires that a specific set of functional and performance requirements (contained in sub-clauses (a) though (j)) be documented in the RRS design manuals. There is no corresponding requirement in the updated N290.4-11 version. Therefore, this is not a gap but is retained for completeness.
186	CSA N290.4-M82 PARTS Review, Clause 4.3.1.2, "Specific Requirements"	PSR1-AD-NFA17	Clause 4.3.1.2 of N290.4-M82 is superseded by N290.4-11 clauses 5.4.2 and 5.4.3, which require that the design target reliability of RRS be established in the Probabilistic Safety Assessment. The Pickering 1,4 Probabilistic Safety Assessment demonstrates that the RRS reliability including any supporting systems is acceptable. Therefore, this is not a gap but is retained for completeness.

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
188	CSA N290.4-M82 PARTS Review, Clause 4.3.25.4, "Identification of System Hardware"	PSR1-AD-NFA18	Clause 4.3.25.4 of N290.4-M82: This requirement refers to practices for human-system interface design. The gap was raised because colour coding for different channels is not used. The Main Control Room panel components are located functionally with the associated system and organized into groupings based on the associated zone. Labels clearly identify the instrument and the associated zone. There are only a limited number of switches. The Main Control Room panels are clearly organized and labeled, such that colour coding to differentiate between channels is not required. There is no longer a specific requirement for colour coding. Therefore, this is not a gap but is retained for completeness.
189	CSA N290.4-11 DNGS ISR Review, Issue D245, "Shutdown System Requirements for Start-up Instrumentation"	PSR1-AD-NFA19	Start-up instrumentation is considered part of Shutdown System functionality. However, related clauses 5.7 and 5.10.1 in N290.4-11 do not contain the requirement for start-up instrumentation to meet N290.1 requirements. Therefore, this is not a gap but is retained for completeness.
224	CSA B51-03 PB ISR Review, Clause 7.5.1.3, "Design Requirements"	PSR1-AD-NFA20	#224: This is not relevant to the present review as the Pickering B SOE/SIS systems do not contain coil-tube boiler blowoff vessels. #225: This is not relevant to the design of SOE/SIS systems at Pickering B. Therefore, these are not gaps but are retained for completeness.
225	CSA B51-03 PB ISR Review, Clause 7.5.2.1, "Cleaning and Inspection Facilities"		
234	IAEA NS-R-1 PB ISR Review, Clause 6.64, "Control and Cleanup of the Containment Atmosphere"	PSR1-AD-NFA21	This PSR1 AD involves requirements for hydrogen cleanup in Containment FADS provides a controlled and monitored release path. Short-term hydrogen control is provided by the Post-LOCA Hydrogen Ignition System (PLHIS). However, the PLHIS was not originally intended to clean up hydrogen in Containment in the longer term. This issue concerning long-term control of hydrogen has been addressed for Pickering with the installation of Passive Auto-catalytic Recombiners and completion of the Fukushima Action Items. Therefore, this is not a gap but is retained for completeness.

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
238	CNSC RD-337 DNGS ISR Review: Issue D070, "Consideration of Decommissioning During Design Phase"	PSR1-AD-NFA22	The scope of this ISR Issue covers future decommissioning considerations of the plant during the design phase. Requirements for the decommissioning phase are not in PSR2 scope. Therefore, this is not a gap but is retained for completeness.
242	CNSC RD-337 DNGS ISR Review: Issue D277, "Primary Heat Transport Coolant Supply for Multi Unit Shutdown"	PSR1-AD-NFA23	The scope of this Darlington ISR Issue covers the HTS coolant inventory for multi-unit events. Clause 8.2.2 of CNSC RD-337 states that the inventory in the reactor coolant system and its associated systems shall be sufficient to support cool down from hot operating conditions to zero power cold conditions without the need for transfer from any other systems. This is not an issue for Pickering, as there are no credits for non-unit D2O identified per the Pickering Units 1,4 and Pickering Units 5-8 Heat Transport System (HTS) Operational Safety Requirements (OSRs). Therefore, this is not a gap but is retained for completeness.
244	CNSC RD-337 DNGS ISR Review: Issue D225, "Fire Protection Water Supply"	PSR1-AD-NFA24	Clause 8.8 of CNSC RD-337 requires that if the fire water supply is interconnected to the emergency heat removal system, operation of one does not impair the operation of the other. This is not an issue for Pickering. Pickering 5-8 have an Emergency Water Supply (EWS) supply to the Heat Transport System. Pickering 1,4 have a manual flowpath that supplies water to the HTS from firewater or Emergency Mitigating Equipment (EME) water. The Darlington ISR issue was also related to fire coincident with LOCA relying on a common Emergency Service Water System. This is not an issue for Pickering where fire water is supplied by Diesel pumps with sufficient redundancy (Pickering 1,4) or High Pressure Service Water (Pickering 5-8). Therefore, this is not a gap but is retained for completeness.
245	CNSC RD-337 DNGS ISR Review: Issue D280, "Off-Gas Management System"	PSR1-AD-NFA25	The Off-Gas Management System is no longer in use. Hence, this is not a PSR2 Gap but is retained for completeness.

AD #	PSR1 AD Title	Group #	PSR1 Grouped AD Title, Description and Rationale
273	NFCC 2005 PB ISR Review: Clause 4.3.7.2, "Construction"	PSR1-AD-NFA26	This AD is related to the requirement for installation of impermeable dyke liners for Standby Generators and the Emergency Power Generator tanks. These dyke liners are now installed. Therefore, this is not a gap but is retained for completeness.
274	PB ISR Emergency Planning SF Review Task #9, "Assess OPG compliance with the interim Part I and Part II of the Provincial Nuclear Emergency Plan (PNEP)"	PSR1-AD-NFA27	**Provincial Nuclear Emergency Plan (PNEP)** This AD involves meeting Provincial Nuclear Emergency Response Plan requirements for emergency planning and response. The Pickering NGS B ISR raised a number of Gaps against the requirements of the then current Provincial Nuclear Emergency Response Plan. Considerable work has been done by OPG since PSR1 on the Consolidated Nuclear Emergency Plan [N-PROG-RA-0001 R014, *Consolidated Nuclear Emergency Plan*, May 2015] to align with the Provincial Nuclear Emergency Response Plan. As concluded in PSR2 Safety Factor 13 OPG Nuclear has: a) adequate plans, staff, facilities and equipment in place for dealing with emergencies, and b) there are adequate arrangements in place for regular emergency training and exercises, and interaction and coordination with local and national authorities. Separate PSR2 reviews were performed for REGDOC-2.10.1, *Nuclear Emergency Preparedness and Response* and CSA N1600-14, *General Requirements for Nuclear Emergency Management Programs*. The OPG nuclear emergency preparedness governance [N-PROG-RA-0001 R015, OPG Nuclear Program, *Consolidated Nuclear Emergency Plan*, November 2016] was revised to ensure that the evacuation time estimates and KI pill programs will be sustained. No further action is required.

Appendix H – Aggregation of Acceptable Deviations by Defence-in-Depth Level

This Appendix evaluates the aggregate impact of PSR1 AD groups as described in Appendix G, together with ADs identified in PSR2. For each level of defence-in-depth, ADs associated with each relevant safety principle are listed, and an evaluation of the impact of the collective set of ADs on the safety principle is provided. This is followed by an overall assessment of the impact of all relevant ADs on the level of defence-in-depth.

This appendix includes PSR1 AD groups and PSR2 ADs that are first assessed for impact against the applicable safety principles for each level of defence. The safety principles provide a structured and comprehensive framework for combining ADs with similar attributes to facilitate assessing their aggregate impact on the barriers provided by each level of defence.

The impact of some ADs was associated with a single safety principle but in other cases a conservative approach was taken to include multiple safety principles that are potentially affected, as follows:

- In the most straightforward cases where there is only one AD associated with a safety principle, determining the aggregate impact of the ADs is simple and straightforward. That is, there is no aggregated effect, by definition.
- In other cases, there is a relatively small number of ADs that can impact on a safety principle and the issues are very minor and totally unrelated (e.g., radiation protection, training programs). In such cases, the assessment of aggregation is again simple and straightforward, and it is concluded that there is no aggregated impact.
- In some cases, some of the safety principles can potentially be impacted by several ADs and determining the combined impact involves assessing the cause of the deviation, the mitigating provisions in place and the extent to which each of the safety principles could potentially be affected. In such cases, a rationale is provided for the aggregation assessment outcome.

For a given defence-in-depth level, the AD groups for each safety principle are cross-compared to confirm that there is negligible aggregate impact on defence-in-depth.

AD Aggregation for Defence-in-Depth Level 1

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
D-150 – Design Management	GI-15-AD1 PSR1-AD13 PSR1-AD14 PSR1-AD15 PSR1-AD19 PSR1-AD20	The following AD and AD groups are assigned to Safety Principle D-150, Design Management: • GI-15-AD1 involves supplier identification of digital items. A requirement for a supplier to self-identify whether their product contains any digital items is not reflected in OPG governing documents. OPG Program [N-PROG-MP-0009-R012, *Design Management,* April 24, 2017] provides the framework for establishment, maintenance and compliance with the design basis for Pickering NGS. The Design Management program specifies requirements for procurement engineering processes ensuring that implementation and maintenance of the physical nuclear facilities meet the design basis requirements. In the event that the use of digital items is identified by OPG in advance of issuing a Request for Proposal or Request for Quotation, existing OPG procedures are adequate for ensuring that requirements related to digital items are documented in the technical specification, including checks and confirmation of the form of equipment supplied. This issue is assessed to be very low safety significance. A Documentation Change Request to update specification preparation governance to require suppliers to identify and describe digital items in equipment provided will be managed outside of the PSR2. • PSR1-AD13 involves CSA N291-08 requirements for Non-Containment Safety-Related Structures. The ADs in this group relate to issues that design documents do not specify requirements that are consistent with those listed in CAN/CSA-N291-08. In PSR2, these issues are assessed to be ADs based on the fact that safety-related structures were designed and analyzed in accordance with the applicable standards at the time, which meet the intent of N291-08. • PSR1-AD14 involves requirements for the zirconium-alloy material used in Pressure Tubes, Calandria Tubes, Reactivity Control Unit tubing, Liquid Injection Shutdown System Nozzles, Guide Tubes, Garter Springs and zirconium alloy wire. Items associated with PSR1-AD14 are assessed to be ADs, on the basis that design documents do not reference the applicable codes and standards or the specific requirements from the codes and standards, but include specifications that align with the required standards. • PSR1-AD15 involves safety-related requirements for plant design. This AD group relates to Single Failure Criterion issues that were raised against IAEA NS-R-1 and

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		CNSC RD-337 and assessed as ADs. The PSR2 review of REGDOC-2.5.2, which adopts principles from NS-R-1 and supersedes CNSC RD-337, included a detailed assessment of PSR1 ADs. Also, the PSR2 assessment of CSA N290.2-11, *Requirements for Emergency Core Cooling Systems of Nuclear Power Plants*, identified an AD for the Pickering 1,4 ECI system, which contains singleton components required to operate for the system to operate successfully, on the basis that all practical modifications were made to the Pickering 1,4 ECI system during Pickering A Return to Service and the system meets its unavailability target. The Pickering NGS design permits testing, maintenance and other necessary activities to be completed while keeping the system available. As stated in the PSR2 code review for REGDOC-2.5.2 [P-REP-03680-00029-R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 1, 5, 6, and 7*, March 2, 2017], this issue was transferred to the Pickering B Continued Operations Plan, where it was closed on the basis that the Level 1 and Level 2 PSA demonstrated that the existing plant design satisfied all safety requirements. The applicability of the gap resolution and subsequent disposition is equally applicable to Pickering 1,4, where the PSAs have similarly been updated. Therefore, this issue is of low safety significance. • PSR1-AD19 involves deterministic safety analysis requirements. The ADs in this group are related to dual trip parameter coverage, the criterion for no dry-out for the first trip, the allowable duration of post dry-out operation for the second trip, and interpretation of the acceptance criterion relating to the acceptable duration of post dry-out operation. However, the derived acceptance criteria outlined in the CANDU Owners Group report [COG-13-9035*, Derived Acceptance Criteria For Deterministic Safety Analysis*, November 2014], developed by the industry taking into account feedback from the CNSC, are less restrictive than those outlined in the current Pickering 1,4 and Pickering 5-8 Safety Reports, providing confidence that the derived acceptance criteria documented in COG-13-9035 will not adversely impact on existing margins as demonstrated in the Safety Reports. As part of the PSR2 review, modern versions of the codes and standards were assessed to determine the extent to which Pickering NGS meets the new standards, namely REGDOC-2.5.2 and REGDOC-2.4.1, including a review of PSR1 ADs. The review confirmed that PSR1 ADs in this group have no impact on nuclear safety. The AD rationale continues to remain applicable and is not impacted by the planned extended operation. • PSR1-AD20 involves National Building Code of Canada requirements to consider various loads in the

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		plant design. The original designs accounted for the uncertainty of the loading and variability of the material properties with established and accepted factors that would result in an acceptable margin of safety. The PSR2 review confirmed that although the recent version of the National Building Code of Canada may introduce new requirements related to these topics, the intent is met by the design. The ADs in this group that relate to barriers in Safety Principle D-150, Design Management, have no significant interaction because the issues are associated with unique SSCs, and individual groups have low or very low safety significance or safety impact. Generally, these ADs are related to legacy design issues which have since been addressed by the on-going maintenance, testing and inspection programs at OPG. Furthermore, OPG Program, N-PROG-MP-0009, *Design Management*, provides the framework for establishment, maintenance and compliance with the design basis for Pickering NGS. The Design Management program provides assurance that design and procedure changes are prepared, reviewed, approved, documented and implemented in accordance with approved procedures, applicable regulatory requirements, standards and industry practices. Therefore, the overall conclusion for D-150 is that the aggregate impact on defence-in-depth of these ADs is negligible and the Pickering NGS Design Management program defines the appropriate processes to ensure nuclear safety requirements are met in the planning and execution of design modifications.
C-255 – Verification of Design and Construction	PSR1-AD3	PSR1-AD3 involves general requirements for Containment Concrete Structures. The original and subsequent revisions of the CSA N287 series of standards were issued after completion of design and construction of Pickering NGS. Therefore, the details related to general requirements of Containment structure, parts, materials, design, fabrication, construction, inspection, examination, testing and commissioning in accordance with the series of standards of CSA N287 are not available. At that time, the Concrete Containment Structures were designed to meet the requirements of the National Building Code of Canada (NBCC) The findings during the PSR1 were assessed to be ADs given robust design practices at the time of the construction, together with ongoing periodic inspections and in-service testing. The standards that applied during original construction of Pickering NGS included requirements for tests and quality control procedures to ensure that the concrete used in the as-built structures met the original design requirements. The PSR2 review of N287.1-14 [P-REP-03680-00029-R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 1, 5, 6, and 7*, March 2, 2017] also outlines Programs,

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		Procedures and Standards which are credited with the ability to detect and monitor any safety significant degradation mechanisms and thus to provide assurance of continued fitness for service of the Pickering NGS Containment Concrete Structures. The AD rationale continues to remain applicable and is not impacted by the planned extended operation. There is only one AD group associated with this safety principle, and therefore there is no aggregate impact for Safety Principle C-255, Verification of Design and Construction.
D-195 – Reactor Core Integrity	PSR1-AD14	PSR1-AD14 involves requirements for material standards for Reactor Components. The technical specifications do not reference the applicable standard but include specifications for mechanical properties, grain size, corrosion properties and inspection requirements that align with the standard. Therefore, the deviation does not pose a safety risk. OPG Program, N-PROG-MP-0009, *Design Management*, provides the framework for establishment, maintenance and compliance with the design basis for Pickering NGS. The Design Management program provides assurance that design and procedure changes are prepared, reviewed, approved, documented and implemented in accordance with approved procedures, applicable regulatory requirements, standards and industry practices. OPG Program [N-PROG-MA-0017 R009, *Component and Equipment Surveillance*, May 31, 2017] defines requirements for establishing programs to ensure the health of selected plant components and equipment. Steam Generators, Fuel and Fuel Channels, Feeder piping, and Reactor Components are covered by formal Life Cycle Management Plans. This program defines the requirements for establishing component programs that manage component and equipment health including inspection, maintenance and testing. OPG program [N-PROG-MA-0025, *Major Components*, March 25, 2015] manages aging of the Major Components (Fuel Channels, Feeders, Steam Generators and Reactor Structures) through a comprehensive program of in-service inspections, maintenance, engineering assessment and confirmatory research and development (R&D). The program is fully developed and effectively implemented for continued validation of fitness for service of the Major Components. The program also incorporates the reporting requirements associated with demonstrating compliance with design basis documentation relevant to each of the Major Components Program areas. This program is identified as a Strength for Pickering NGS. OPG has robust and multi-faceted SSC inspection, monitoring and assessment programs, such that the current condition of the plant is well understood. This provides a sound baseline for extended operation

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		as well as confidence that the requisite data will continue to be acquired. Maintenance programs are aligned with industry best practice and are carried out in accordance with written procedures that are part of the overall Management System. OPG program [N-PROG-MA-0026, *Equipment Reliability*, May 26, 2015] ensures that there are defined activities ensuring that the current condition of the equipment is understood, and that equipment aging issues are identified, understood and effectively managed for equipment important to nuclear safety and equipment reliability. This program and the Major Components program are identified as a Strength for Pickering NGS. System Health reporting, which is an integral element of the Equipment Reliability Program, is also identified as a Strength. There is only one AD group associated with this safety principle, and therefore there is no aggregate impact for Safety Principle D-195, Reactor Core Integrity.
D-186 – Inspectability of Safety Equipment	GI-16-AD1	GI-16-AD1 is also covered under O-305 Maintenance, Testing and Inspection. This AD group is related to concessions in the periodic inspection plans for components that are inaccessible. The CNSC has accepted the reasonableness of the solution to this issue and has determined that the revised PIPs satisfactorily meet the requirements of CSA N285.5-08 Update No. 1 standard. Furthermore, as indicated in the resolution for GI-16-AD1 in Appendix B of this report, where the inspection of a system or component would necessitate the dismantling of equipment, the required inspection should be performed when the equipment is dismantled for other reasons (i.e., maintenance). There is only one AD associated with this safety principle, and therefore there is no aggregate impact for Safety Principle D-186, Inspectability of Safety Equipment.
D-205 – Startup, Shutdown and Low Power Operation	PSR1-AD10	PSR1-AD10 involves requirements for RRS related to Start-up Instrumentation, documentation, reliability, and human-system interface. These issues were identified during the PARTS review and are related to the requirement for the operator to initiate monitoring of the flux tilt and initiate power reduction as needed. The control systems in Pickering NGS maintain the reactor operating conditions within the normal operating range, and effectively respond to anticipated transients to avoid the need for safety system action. Reactor control in Pickering NGS has a high degree of immunity to process upsets, measurement failures, etc., due to extensive redundancy in control devices and process measurements. The ability to maintain control in the presence of partial system failures, combined with high reliability of the Dual Computer Control System, leads to a very high availability of the Reactor Regulating System, which

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		controls reactor power. The Reactor Regulating System also controls operational reactivity transients. As detailed in Appendix D for Safety Principle D-205, Pickering NGS has the SSCs in place to control the reactor power and provide core cooling in response to events occurring during startup, shutdown and low power operation, confirming that this AD group is an AD for PSR2. There is only one AD group associated with this safety principle, and therefore there is no aggregate impact for Safety Principle D-205, Startup, Shutdown and Low Power Operation.
O-305 – Maintenance, Testing and Inspection	GI-16-AD1 GI-20-AD1 GI-20-AD2	The following ADs are assigned to Safety Principle O-305. • GI-16-AD1 is related to the extent of inspection of Containment components deemed inaccessible for inspection. • GI-20-AD1 involves developing an implementation plan for reviewing and updating Condition Assessments. • GI-20-AD2 concerns oversight and implementation of the Integrated Aging Management program [N-PROG-MP-0008, *Integrated Aging Management*, May 2, 2016] All of these ADs involve refinements or improvements to existing effective OPG processes for maintenance, testing and inspection, and none indicates a concern with the actual condition of the Pickering NGS SSCs. For aggregation, the ADs are grouped into 2 categories: • An AD that focuses on a specific aspect (GI-16-AD1). The CSA N285.5 issues in this AD involve governance for removal of insulation and the inspection interval. The Compliance Matrices in the relevant Pickering NGS Periodic Inspection Plans [NK30-PIP-03642.2-00001 R003, OPG Plan, *Pickering Nuclear Generating Station "B" Periodic Inspection Program for Containment Components*, July 31, 2012], [NA44-PIP-03642.2-00001 R002, OPG Plan, *Pickering Nuclear Generating Station "A" Periodic Inspection Program for Containment Components*, July 31, 2012] and [P-PIP-03642.2-00001 R003, OPG Plan, *Pickering Nuclear Generating Station Periodic Inspection Program for Unit 0 Containment Components*, July 31, 2012] state that full or partial disassembly of components for the purpose of inspection will not be undertaken specifically for periodic inspection, as this may result in component damage. These Periodic Inspection Plans have been accepted by the CNSC. Furthermore, as indicated in the resolution for GI-16-AD1 in Appendix B of this report, where the inspection of a system or component would necessitate the dismantling of equipment, the required inspection should be performed when the equipment is dismantled for other reasons (i.e., maintenance).

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		The issue is assessed as a very low safety significance AD with no further action. • ADs that are of broader impact, and therefore overlap the more specific ADs (GI-20-AD1 and GI-20-AD2) OPG is actively progressing the tasks covered by both GI-20-AD1 and GI-20-AD2 for the extended operating period. OPG has robust and multi-faceted SSC inspection, monitoring and assessment programs, such that the current condition of the plant is well understood. This provides a sound baseline for extended operation as well as confidence that the requisite data will continue to be acquired. Maintenance programs are aligned with industry best practice and are carried out in accordance with written procedures that are part of the overall management system. Therefore, the overall conclusion for O-305 is that the aggregate impact on defence-in-depth of these ADs is very low, and mitigated by the maintenance, testing and inspection programs in place.
O-284 – Operating Limits and Conditions	GI-11-AD1 PSR1-AD2	GI-11-AD1: This AD is related to providing additional information on the Fuel Management and Surveillance Software and updating Operational Safety Requirements documents (SOE) for Fuel. OPG is actively progressing completion of the OPG commitment to provide additional information to address the related Action Item 2016-OPG-8250. Since the issue associated with the AD will be closed in the near future, this AD does not pose any risk to the plant for extended operation and there is no aggregation impact. PSR1-AD2 involves issues relating to Staffing, the Human Factors Engineering (HFE) Program [N-MAN-06700-10002, *Guide for OPG Human Factors Engineering Process*, December 18, 2015] and Verification and Validation during the design process. Some of the issues in this AD group deal with the requirement in CNSC Guide G-323 that the minimum staff complement be determined by the licensee through a systematic analysis and practical validation. Changes in the minimum shift complement as a result of these actions are identified in an OPG letter to the CNSC, [P-CORR-00531-03710, *Pickering A and B Request for Licence Amendments – Minimum Shift Complement*], wherein it is noted that: "The validation methodology has been documented and validation exercises have been observed by CNSC Staff." Therefore, there is no longer a gap in this area. The Pickering B ISR raised a gap on the basis that for smaller modifications, explicitly documenting each validation element was not judged necessary. HFE evaluates the role of humans in human-machine systems and how systems can be designed to work

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		well with people, particularly in terms of safety and efficiency. Operation of the Pickering NGS design over the years has demonstrated that the plant layout and facilities provide a safe working environment. Operating experience and improvements have been incorporated into the processes and design to improve the human-machine interfaces in many areas (e.g., Control Room annunciation upgrades as a result of changes to computer hardware and operator interface). Additionally, training and qualification processes (and certification processes for Control Room staff) for Operations positions ensure that the staff are competent to carry out functions assigned to them. The simulator is used extensively for initial training and qualification, as well as for refresher/requalification training. For example, per N-INS-08920-10002, *Simulator-Based Initial Certification Examinations for Shift Personnel*, Simulator Exercise Guides are used as part of training for certified staff. Since 2000, HFE has been explicitly considered for all design changes at Pickering NGS, resulting in continuous improvements to the human-machine interfaces throughout the plant. The PSR2 review confirmed that the Human Factors Engineering Program Plans [N-MAN-06700-10002-R004, *Guide for OPG Human Factors Engineering Process*, December 18, 2015] are prepared by OPG meet the requirements of CNSC G-276 and CNSC G-278, as well as applicable elements from NUREG-0711. This program is identified as a Strength for Pickering NGS. The assessment presented above shows that both areas have been fully addressed at Pickering NGS and therefore, these ADs do not contribute to the aggregation for Level 1.
O-278 – Training	PSR1-AD2	PSR1-AD2 involves issues relating to the Human Factors Engineering Program and Verification and Validation during the design process. The ADs were identified for smaller modifications where explicitly documenting each validation element was not judged necessary. Pickering NGS was originally designed to the standards of the day and designers relied on best design practices in addition to incorporation of operations and maintenance experience. The PSR2 assessment in the Safety Factor 1 Report confirmed that Pickering NGS has demonstrated that the plant layout and facilities provide a safe working environment. The training and qualification processes (and certification processes for Control Room staff) in place for Operations positions ensure that the staff are competent to carry out functions assigned to them. In addition, the PSR2 review confirmed that Human Factors Engineering Program Plans meet the requirements of CNSC G-276 and CNSC G-278, as well as applicable elements from NUREG-0711. This program is identified as a Strength for Pickering NGS. There is only one AD group associated with this safety principle, and therefore there is no aggregate

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		impact for Safety Principle O-278, Training.
D-188 – Radiation Protection in Design	PSR1-AD17	PSR1-AD17 is assigned to Safety Principle D-188. This AD group involves IAEA requirements for radiation protection. IAEA NS-R-1 requires that consideration of the buildup of radiation levels with time in areas of personnel occupancy is to be provided for in the design of the plant and in housekeeping practices during the conduct of operating and maintenance activities. At OPG, this is done with the objective of minimizing exposures of station personnel and the generation of radioactive materials as waste. In addition, the review in the Safety Factor 15 Report has confirmed that Radiation Protection has been adequately accounted for in the design and operation of Pickering NGS, and that Radiation Protection provisions (including design and equipment) provide adequate protection of persons from the harmful effects of radiation and ensure that contamination and radiation exposures and doses to persons are monitored and controlled and maintained ALARA. Furthermore, the Regulatory Oversight Report for Canadian Nuclear Power Plants: 2015 states that CNSC staff concluded that the “Radiation Protection” and “Operating Performance” Safety and Control Areas at Pickering met or exceeded performance objectives and all applicable regulatory requirements, and rated these Safety and Control Areas as Fully Satisfactory. There is only one AD group associated with this safety principle, and therefore there is no aggregate impact for Safety Principle D-188, Radiation Protection in Design.
S-136 – External Factors Affecting the Plant	GI-13-AD1 GI-13-AD2 GI-13-AD3 GI-13-AD4 GI-43-AD1 PSR1-AD1	The following ADs and AD groups are assigned to Safety Principle S-136. GI-13-AD1: This AD is related to the CSA N289.3 requirements to confirm that a) the generated time history used within seismic analyses of safety-related systems correctly represents the design ground response spectrum for the Pickering site in compliance with CSA N289.3-10, and b) the power spectral density (PSD) function of each time-history has been calculated and shown to not have any significant gaps in energy over the frequency intervals. The rationale for considering this gap as an AD is the time-history method is a typical method for seismic qualification that has been employed at Pickering NGS. Time-history ground motion inputs at Pickering NGS were established based on the requirements of CSA N289.3-M81 and that the seismic analysis method is conservative and adequate, which is confirmed by the Pickering Seismic PRA that concludes the seismic design of systems and structures are sound. Consequently these gaps are considered to have no impact on the seismic resistance of qualified structures. GI-13-AD2: This AD is related to the CSA N289.4-12 requirements for confirmation that aging effects that

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		may impair seismic functionality shall be accounted for in seismic qualification by testing. Routine monitoring measures ensure that degradation effects will not be permitted to advance to the extent that seismic functionality is impaired. OPG's commitment [N-CORR-00531-05661, Design Codes and Standards Effective Dates for OPG Nuclear Fleet, April 2012] to using CSA N289.4-12 for testing procedures for seismic qualification of nuclear power plant SSCs will ensure that the requirements will be followed. Also, administrative controls [N-STD-MP-0025, *General Requirements For Seismic Qualification of OPG Nuclear Facilities*, October 27, 2016] ensure that seismic qualification of SSCs performing safety-related functions during and following an earthquake is maintained for the life of the facility. Consequently this gap is considered to have no impact on the seismic resistance of equipment qualified by test. GI-13-AD3: This AD is related to the CSA N289.5 requirement for seismic monitoring/recording. OPG has installed in-plant seismic instrumentation to monitor seismic activity at Pickering NGS (and at Darlington) in compliance with CSA standard N289.5 [NK30-DM-61150-10001, *Pickering Nuclear: Seismic Monitoring System*, September 2013; N-GUID-02004-10000-R00, Seismic Monitoring of OPG Nuclear Generating Stations, December 2010]. OPG has established procedures - Abnormal Incidents Manuals - that detail station response to earthquakes. Clear responsibilities are established to support monitoring and post-seismic response to an event [NK30-AIM-058-09013-6.0, *Abnormal Incident Manual: Seismic/Common Mode Event*; NA44-AIM-014-09013-06, *Abnormal Incident Manual: Seismic Event*]. OPG is also a contributor to the operation of the Southern Ontario Seismic Network (SOSN) which provides detailed free-field seismic records covering Southern Ontario. These systems support in-plant monitoring of the station's response to seismic events. The intent of the requirements has been met, and for these reasons, and as per the very low safety significance (Safety Significance Level 4), this is assessed as an Acceptable Deviation with no further action. GI-13-AD4 (for Units 1 and 4 only): This AD is related to a requirement in CSA N289.3 for the minimum number of cycles used for seismic fatigue analysis for the level of compliance of Pickering NGS plant structures supporting the operation of Pickering NGS reactors in the context of extended operation. Pickering Units 1,4 Class 1 systems and components are designed to ASME Code Section III which betters the CSA N289.3 requirement, including required cycles for fatigue analysis. Also, Seismic Margin Assessment is an accepted method for assessing seismic qualification and as such, this is an Acceptable Deviation for Pickering 1,4. For continuing analysis of potential new modifications, the requirements of CSA N289.3-10 with regards to number of cycles for seismic fatigue analysis would be met or bettered, consistent with the modelling methodology in place at OPG for such work as noted above. For these reasons, and as per the very low safety significance (Safety Significance Level 4), this is assessed as an

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		Acceptable Deviation for Pickering 1,4 with no further action. GI-43-AD1: This AD is related to a new requirement in CSA N291-15 for bolted connections in members that are part of the seismic load resisting system. The original code requirements for PNGS safety related structures [National Building Code of Canada] and the Seismic Margin Assessments (SMA) include requirements of CSA S16 “Design of Steel Structures”, which is the basis for the requirements for bolted connections of steel structures in CSA N291-15. Given that the SMA methodology and the plant design both include requirements of S16/S16.1 (predecessor of S16), the plant meets or has been assessed to these requirements. As it would not be practicable to make changes to the bolted steel connections in the existing structural design, and given the low safety significance (Significance Level 3), this is assessed as an Acceptable Deviation with no further action. PSR1-AD1 involves requirements for seismic-qualification. The following issues in PSR1-AD1 were raised in the Darlington and Pickering B ISRs. In terms of Safety Analysis, CSA N289.2 does not specify any specific requirements relating to the seismic success path. It is focused on a systematic approach to identify the seismic hazard. As such, there are no specific clauses relating to Safety Analysis. However, it is recognized that the magnitude and frequency of the spectra impacts on the qualification of SSCs and that if their required qualification were to change, the success path may need to change. The Darlington ISR raised a gap against Clause 5.5.2.1 of CSA N289.3 because the time histories are not statistically independent. The issues in PSR1-AD1 generally relate to the seismic design report of DNGS structures not explicitly accounting for effects due to • soil-structure interaction (SSI), • the difference between modeling techniques and analysis approaches for the evaluation of the site response analysis for the free-field case, and • complete interaction versus the sub-structure technique for the soil/foundation/structure system. These issues are also applicable to Pickering NGS. The Periodic Inspection of the concrete structures and routine leakage tests of the Containment envelope verify that there is no significant deterioration in the integrity of the Concrete Containment Structures. The rationale for considering gaps related to seismic qualification as an AD is that the seismic PRA confirms that Pickering NGS conforms to CNSC S-294 and to various international guides on seismic

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		PRA, and that the results are acceptable. Consequently these ADs are considered to have no impact on the seismic resistance of qualified structures. This AD group is therefore deemed to have no impact on this aggregation assessment. GI-13-AD1, GI-13-AD4 and GI-43-AD1 have the same attribute “Seismic Design” insofar as the gaps are all related to the design programs by which the qualified SSCs were designed. While this is a common factor, the seismic design of Pickering NGS has been shown to be conservative such that all qualified SSCs will withstand the effects of a design basis seismic event. The seismic design aspect covered by PSR1-AD1 regarding soil structure interactions and GI-13-AD3 for monitoring have nothing in common with the other ADs with the attribute “Seismic Design”. Hence there is no aggregation effect. The aggregate impacts of these 6 seismic ADs on Pickering NGS seismic design integrity capability is negligible and hence has no impact on public safety.
O-269 – Safety Review Procedures	GI-30-AD1	GI-30-AD1 concerns methodology and processes for evaluation of instantaneous risk. An industry initiative is underway to develop a methodology and processes for evaluation of instantaneous risk. The current instantaneous risk monitoring uses the At-Power and Outage Internal Events PSA models. At-Power and Outage instantaneous risk Safety Goal monitoring is proceduralized and implemented regularly for online maintenance and during each unit outage. OPG is continuing to participate in the industry initiative on further evaluation of instantaneous risk. Operationalization of Probabilistic Safety Assessment is a Strength for Pickering NGS. PSA is used to support the conduct of engineering, maintenance and operation at Pickering NGS as follows: • Proposed modifications to plant operation, configuration or procedures that may significantly increase the risk of a severe accident are reviewed to quantify impact on risk and to assess its acceptability. Similarly, any modifications that may reduce risks are to quantify the benefits in terms of impact on risk as in input to decision-making. • PSA assumptions important to safety regarding inspection, testing and maintenance are identified and incorporated into operating and maintenance procedures. • PSA is used to identify accident scenarios. • PSA is used to support in-plant and ex-plant consequence analyses for event sequences beyond the design basis for use in understanding severe accident progression and management, as allowed by

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		the scope and limitations of the PSA. There are other processes at Pickering NGS that provide assurance of defence-in-depth during temporary outage or maintenance alignments, and these deterministic considerations apply regardless of the potential hazard. Evaluation of instantaneous risk using additional instantaneous risk tools beyond the current at-power and outage risk assessments is considered an enhancement to the existing means that OPG has for determining risks during normal operation and planned events. Therefore, this issue has no impact on the aggregate assessment of ADs in this Level. There is only one AD associated with this principle, and therefore there is no aggregate impact for Safety Principle O-269, Safety Review Procedures.
M&C-246 – Safety Evaluation of Design	PSR1-AD15 PSR1-AD19 PSR1-AD22	The following AD groups are assigned to Safety Principle M&C-246. • PSR1-AD15 involves safety-related requirements for plant design. This AD group relates to Single Failure Criterion issues that were raised against IAEA NS-R-1 and CNSC RD-337 and assessed as ADs. The PSR2 review of REGDOC-2.5.2, which adopts principles from NS-R-1 and supersedes CNSC RD-337, included a detailed assessment of PSR1 ADs. Also, the PSR2 assessment of CSA N290.2-11, “Requirements for Emergency Core Cooling Systems of Nuclear Power Plants", identified an AD for the Pickering 1,4 ECI system, which contains singleton components required to operate for the system to operate successfully, on the basis that all practical modifications were made to the Pickering 1,4 ECI system during Pickering A Return to Service and the system meets its unavailability target. The Pickering NGS design permits testing, maintenance and other necessary activities to be completed while keeping the system available. As stated in the PSR2 code review for REGDOC-2.5.2 [P-REP-03680-00029-R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 1, 5, 6, and 7*, March 2, 2017], this issue was transferred to the Pickering B Continued Operations Plan, where it was closed on the basis that the Level 1 and Level 2 PSA demonstrated that the existing plant design satisfied all safety requirements. The applicability of the gap resolution and subsequent disposition is equally applicable to Pickering 1,4, where the PSAs have similarly been updated. Therefore, this issue is of low safety significance. • PSR1-AD19 involves deterministic safety analysis requirements. The ADs in this group are related to dual trip parameter coverage, the criterion for no dry-out for the first trip, the allowable duration of post dry-out operation for the second trip and interpretation of the acceptance criterion relating to the acceptable duration of post dry-out operation. However, the

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		derived acceptance criteria outlined in the COG report [COG-13-9035*, Derived Acceptance Criteria For Deterministic Safety Analysis*, November 2014], developed by the industry taking into account feedback from the CNSC, are less restrictive than those outlined in the current Pickering 1,4 Safety Report [NA44-SR-01320-00002-R004, *Pickering Nuclear 1-4 Safety Report: Part 3 – Accident Analysis*, October 31, 2013] and Pickering 5-8 Safety Report [NK30-SR-01320-00003-R004, *Pickering Nuclear 5-8 Safety Report: Part 3 – Accident Analysis*, October 30, 2014], providing confidence that the derived acceptance criteria documented in COG-13-9035 will not adversely impact on existing margins as demonstrated in the Safety Reports. The PSR2 review confirmed that the PSR1 AD rationale for PSR1-AD19 continues to remain applicable and is not impacted by extended operation. • PSR1-AD22 - These ADs are related to requirements for development, verification and review of computer programs used for Safety Analysis, as well as requirements for software validation. OPG has ensured quality in the development of its safety analysis tools. OPG has been participating in an industry-wide COG program addressing software validation. Industry efforts towards industry standard toolsets and Generic Action Item 98G02 *Validation of Computer Programs Used in Safety Analysis of Power Reactors* detail some of the work ongoing to comply with CNSC guide G-149 (2000), Computer Programs Used In Design and Safety Analyses of Nuclear Power Plants and Research Reactors. CNSC Generic Action Item GAI 98G02 was closed with the CNSC concluding that OPG (and industry) established an acceptable process to improve computer code validation by achieving an overall level of baseline validation for a specific set of major computer codes used in safety analyses. Also, a review of CNSC guide G-149 (2000) was performed at a high level as part of the Pickering B ISR which confirmed that OPG's governance and processes adequately addressed the intent of the guide. Based on the justification above, the quality assurance of computer codes is considered to be sufficient at the overall level, so the effect of this issue is limited without impairing the capability of safety provisions. The results of the Darlington ISR from the perspective of G-149 are considered applicable to Pickering 1,4 and 5-8, given that the assessment was performed against OPG governance applicable to all of the OPG Nuclear fleet. The ADs in this group that relate to barriers in Safety Principle M&C-246, Safety Evaluation of Design, have no significant interaction because the issues are not cumulative in nature and individual groups have

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		low safety significance or safety impact. Also, these ADs are related to issues which, for the most part, have been addressed to minimize any potential risk to plant operation. In the case of issues related to the Single Failure Criterion, Level 1 and Level 2 PSA demonstrate that the existing plant design satisfies all PSA-related safety requirements. The ADs related to Fuel and Fuel Channel derived acceptance criteria are addressed in the current Pickering 1,4 and Pickering 5-8 Safety Reports, providing confidence that the derived acceptance criteria documented in industry accepted report [COG-13-9035*, Derived Acceptance Criteria For Deterministic Safety Analysis*, November 2014] will not adversely impact on existing margins. For ADs related to requirements for development, verification and review of computer programs used for Safety Analysis, the quality assurance of computer codes is considered to be sufficient at the overall level, so that the effect of this issue is limited without impairing the capability of safety provisions. Therefore, the overall conclusion for M&C-246 is that the aggregate impact on defence-in-depth of these ADs is negligible.
M&C-249 – Achievement of Quality	PSR1-AD22	PSR1-AD22 is related to requirements for the development, verification and review of computer programs used for Safety Analysis, as well as requirements for software validation. The full scope of OPG governance establishes a QA program that is robust and compliant, and thus ensures the development of Scientific, Engineering and Safety Analysis software is adequately aligned with the requirements of CNSC G-149 and CSA N286.7. The OPG Program, N-PROG-MP-0009, *Design Management*, provides requirements relevant to the design and development of Scientific, Engineering and Safety Analysis software. The requirements for design inputs and design outputs are given in the Design Management program. This provision in the governance requires definition of the inputs and outputs as part of the software design process. This governing document also addresses requirements for a formal Design Plan, with instructions on the need for stakeholder input during the design process. This AD group is also assessed under M&C-246, Safety Evaluation of Design. The assessment concludes that the quality assurance of computer codes, including legacy codes, is sufficient at the overall level, so the effect of this issue is limited without impairing the capability of safety provisions. The results of the Darlington ISR from the perspective of G-149 are considered applicable to Pickering 1,4 and 5-8, given that the assessment was performed against OPG governance applicable to all of the OPG Nuclear fleet. There is only one AD group associated with this principle, and therefore there is no aggregate impact for

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		Safety Principle M&C-249, Achievement of Quality.

Overall AD Aggregation for Defence-in-Depth Level 1
The ADs associated with the safety principles in Level 1 defence-in-depth cover the following diverse areas. • D-150 – Design Management –The ADs associated with Safety Principle D-150, Design Management, have no significant interactions because the issues are against unique SSCs, and individual groups have low or very low safety significance or safety impact. OPG's Design Management Program, OPG-PROG-MP-0009, specifies requirements for procurement engineering processes ensuring that implementation and maintenance of the nuclear facilities meet the design basis requirements. The Design Management Program provides assurance that design and procedure changes are prepared, reviewed, approved, documented and implemented in accordance with approved procedures, applicable regulatory requirements, standards and industry practices. • C-255 – Verification of Design and Construction - The findings during the PSR1 were assessed to be ADs given the robust design practices at the time of construction, together with ongoing periodic inspections and in-service testing. The AD rationale continues to remain applicable and is not impacted by the planned extended operation. There is only one AD group associated with this safety principle, and therefore there is no aggregate impact. • D-205 – Startup, Shutdown and Low Power Operations - As detailed in Appendix D for Safety Principle D-205, Pickering NGS has SSCs in place to control the reactor power and provide core cooling in response to events occurring during startup, shutdown and low power operation, confirming that this AD group is an AD for PSR2. There is only one AD group associated with this safety principle, and therefore there is no aggregate impact for Safety Principle D-205, Startup, Shutdown and Low Power Operation. • D-195 – Reactor Core Integrity – This safety principle has only one associated AD group, which is mitigated by multiple OPG programs related to management of design, surveillance of components and equipment, and equipment reliability. The Equipment Reliability Program, N-PROG-MA-0026, and the Major Components Program, N-PROG-MA-0025 are identified as Strengths for Pickering NGS. • D-186 – Inspectability of Safety Equipment – The associated AD group is related to concessions in the Periodic Inspection Plans for components that are deemed inaccessible. Although the issue relates to inspection requirements for inaccessible areas, the CNSC has been informed and accepted the revised PIPs in terms of meeting the requirements and the remedial steps identified in the CSA N285.5-08, *Periodic inspection of CANDU Nuclear Power Plant Containment Components*, Update No. 1 standard. This is not impacted by the planned extended operation beyond 2020. • D-188 – Radiation Protection in Design – The Safety Factor 15 Report has confirmed that Radiation Protection is adequately accounted for in the design and operation of Pickering NGS, and that Radiation Protection provisions (including design and equipment) provide adequate protection of persons from the harmful effects of radiation and ensure that contamination and radiation exposures and doses to persons are monitored and controlled and maintained ALARA. • S-136 – External Factors Affecting the Plant – Seismic PRAs have been issued for Pickering 1,4 and Pickering 5-8 that confirm that Pickering NGS conforms to CNSC S-294 and to various international guides on seismic PRA. Consequently these ADs have no impact on the seismic resistance of qualified structures. Therefore, these ADs do not contribute to aggregation or pose any significant risk. • O-269 - Safety Review Procedures – There are deterministic rules at Pickering NGS that provide assurance of defence-in-depth during

Overall AD Aggregation for Defence-in-Depth Level 1
temporary outage or maintenance alignments, and these deterministic considerations apply regardless of the potential hazard. Evaluation of instantaneous risk using PSA is considered an enhancement to the existing means that OPG has for determining risks during normal operation and planned events. • O-305 - Maintenance, Testing and Inspection – This is area has numerous ADs and interactions were identified. However, OPG has a robust and multi-faceted SSC inspection program, such that the current condition of the plant is well understood. This provides a sound baseline for extended operation as well as confidence that the requisite data will continue to be acquired. In addition, maintenance programs are aligned with industry best practice and are carried out in accordance with written procedures that are part of the overall management system. • O-284 - Operational Limits and Conditions – There are two groups of ADs for this safety principle. However, one related to Minimum Staff Complement has been closed. The other related to Human Factors Engineering has been addressed by means of a very strong and robust Human Factors Engineering program [N-MAN-06700-10002-R004, *Guide for OPG Human Factors Engineering Process,* December 18, 2015]. PSR2 review confirmed that Human Factors Engineering Program Plans prepared by OPG meet the requirements of CNSC G-276 and CNSC G-278, as well as applicable elements from NUREG-0711. • O-278 – Training – One AD was assessed for this safety principle, related to smaller modifications where explicitly documenting each validation element was not judged necessary. The PSR2 assessment in Safety Factor 1 Report confirmed that the Pickering NGS plant layout and facilities provide a safe working environment. The training and qualification processes (and certification processes for Control Room staff) in place for Operations positions ensure that the staff are competent to carry out functions assigned to them. • M&C-246 – Safety Evaluation of Design – The groups of ADs have no significant interaction because the issues are not cumulative in nature and individual groups have low safety significance or safety impact. Also, these ADs are related to issues which, for the most part, have been addressed to minimize any potential risk to plant operation. • M&C-249 – Achievement of Quality – One AD was assessed for this safety principle. The AD is related to requirements for the development, verification and review of computer programs used for Safety Analysis, as well as requirements for software validation. The full scope of OPG governance establishes a QA program that is robust and compliant, and thus ensures the development of Scientific, Engineering and Safety Analysis software is adequately aligned with the requirements of relevant codes and standards. Some of the ADs have the same attribute 'Design' insofar as the gaps are all related to the design program by which the qualified SSCs were designed. While this is a common factor, the design of Pickering NGS has been shown to be conservative, and conformance to the design basis is continually confirmed by analysis and by the ongoing maintenance, testing and inspection programs at OPG. Equipment Reliability and maintenance, testing and inspection have several ADs and interactions were identified. However, OPG has robust and multi-faceted SSC inspection, monitoring and assessment programs, such that the current condition of the plant is well understood. This provides a sound baseline for extended operation as well as confidence that the requisite data will continue to be acquired. Maintenance programs are aligned with industry best practice and are carried out in accordance with written procedures that are part of the overall

Overall AD Aggregation for Defence-in-Depth Level 1
management system. Regular preventive and predictive maintenance, inspection, testing and servicing of SSCs important to safety and reliability are conducted to maintain SSCs within their design basis. Implementation and execution of Pickering NGS's Equipment Reliability Program, N-PROG-MA-0026, is identified as a Strength for Pickering NGS, as is the Major Components Program, N-PROG-MA-0025. Common attributes related to Human Factors Engineering are addressed by the demonstrated safe and effective working environment at Pickering NGS. The programs for initial, refresher, and upgrade training and qualification processes (and certification processes for Main Control Room staff) are in place for Operations positions and ensure that the staff are competent to carry out functions assigned to them. The aggregate impact of the ADs for each safety principle is determined to have no significant impact on safety. Furthermore, the overall aggregate impact of all of the ADs associated to Level 1 defence-in-depth is assessed to be low.

AD Aggregation for Defence-in-Depth Level 2

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
D-158 – General Basis for Design	GI-31-AD1 GI-44-AD1	The following ADs are assigned to Safety Principle D-158. • GI-31-AD1 involves consideration of AOOs in the Pickering NGS Deterministic Safety Analysis. • GI-44-AD1 is related to REGDOC-2.5.2 requirements and limits for AOOs, DBAs and BDBAs. As part of the PSR2 review, modern versions of the codes and standards were assessed to determine the extent to which Pickering NGS conforms with safety-significant requirements of the new standards, namely CNSC REGDOC-2.5.2 and CNSC REGDOC-2.4.1. Required system performance under accident conditions is addressed in the Pickering 1,4 Safety Report [NA44-SR-01320-00002-R004, *Pickering Nuclear 1-4 Safety Report: Part 3 – Accident Analysis*, October 31, 2013] and Pickering 5-8 Safety Report [NK30-SR-01320-00003-R004, *Pickering Nuclear 5-8 Safety Report: Part 3 – Accident Analysis*, October 30, 2014]. Also, a full range of initiating events, including AOO-type sequences, is considered in the PSAs [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014]. However, the term AOO is not used in the current Pickering Safety Reports even though AOO-type sequences are assessed. Pickering NGS has a comprehensive list of events (Initiating Events) defined for the safety analyses that are modelled in the PSA and the risk is acceptably low. Consideration of the identification and analysis of AOOs is addressed under REGDOC-2.4.1 implementation. The implementation plan will be updated in accordance with the Licence Conditions Handbook and will identify any changes required to support the continued safe operation of Pickering NGS. These changes will be informed by the timeline of the Darlington REGDOC-2.4.1 Implementation Plan and the limited additional years of Pickering NGS operation. Level 2 defence-in-depth is achieved by detecting deviations from normal operating conditions by the Reactor Regulating System and plant process and control systems. The control systems in Pickering NGS maintain reactor operating conditions within the normal operating range, and effectively respond to anticipated transients to avoid the need for safety system action. Reactor control in Pickering NGS has a high degree of immunity to process upsets, measurement failures, etc., due to extensive redundancy in control devices and process measurements. The ability to maintain control in the presence of partial system failures, combined with high reliability of the Dual Computer Control System, leads to a very high availability of the Reactor Regulating System, which controls reactor power.

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		As regards Level 2 defence-in-depth, both of these ADs cover the same requirements for consideration of AOOs. Both ADs are being addressed by OPG through updating the REGDOC-2.4.1 Implementation Plan for extended operation. Therefore, the aggregate impact of these ADs on defence-in-depth is assessed to be negligible.
D-205 – Startup, Shutdown and Low Power Operation	PSR1-AD10	PSR1-AD10 involves CSA N290.4, Requirements for Reactor Control Systems of Nuclear Power Plants, requirements for the Reactor Regulating System (RRS) related to Start-up Instrumentation, documentation, reliability, and human-system interface. These issues were identified during the Pickering A Return to Service (PARTS) review, and are related to the requirement for the design of the Reactor Regulating System and for the operator to initiate monitoring of the flux tilt and initiate power reduction as needed. The PSR2 confirms the continued applicability of ADs on the following basis: 1. The standard requires the Reactor Regulating System to be physically and functionally separated from the Special Safety Systems. (This is related to clause 5.2 in CSA N290.4-11). Special Safety Systems and the Reactor Regulating System are mostly independent of the major control loops, but there are three exceptions identified in the code review: • Sharing of taps and impulse lines from flow orifices in reactor flow measurement loops between RRS and Shutdown System A (SDSA). The code review states that irrational inputs to RRS control programs are rejected and SDSA channel flows are continually monitored in the Control Room to ensure they remain in the normal operating range. Therefore this is assessed as an AD with no safety impact. • There are a number of RRS hardware and program interlocks related to the shutdown function, e.g., gradually filling all zones when the reactor is tripped. These interlocks do not affect SDS functionality and are standard practice in CANDU design. Also, these interlocks drive RRS reactivity devices in the safe direction. Therefore this is assessed as an AD with no safety impact. • In the control of Moderator level, RRS and ECI share some components, i.e., the common Helium bubbler supply in the Calandria and Dump Tank level measurements. The loss of the bubblers does not result in a loss of regulation, therefore there will be no postulated demand on either the in-core logic or ECI injection from this event and, therefore, sharing the bubblers is acceptable with no safety impact. 2. An AD is identified with clause 4.3.1.2 of CSA N290.4, which requires that all components of the system (including power sources) shall be included in the reliability calculations. This clause is

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		superseded by CSA N290.4-11 clauses 5.4.2 and 5.4.3, which require the design target reliability of RRS be established in the Probabilistic Safety Assessment. The Pickering 1,4 Probabilistic Safety Assessment [P-REP-03611-00006-R000, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan,* April 30, 2014] demonstrates that the RRS reliability including any supporting systems is acceptable. Therefore this is assessed as an AD with no safety impact. 3. Clause 4.3.6.1 requires RRS to control neutron flux to obtain an acceptable spatial distribution and be capable of counteracting flux distortions that may otherwise cause Fuel bundle or channel power limits to be exceeded. (This is related to CSA N290.4-11 clause 4.1.2 (c)). Pickering 1,4 are not equipped with automatic reactor power setback or an alarm based on high flux tilt. Flux tilts are managed by operator monitoring and by the initiation of a power reduction as specified in operating manuals. This deviation has been accepted by the CNSC. Therefore this is assessed as an AD with no safety impact. 4. Clause 4.3.25.4 requires that where a number of channels of one system are in proximity, colour coding is the preferred identification method. This is not implemented in the Pickering 1,4 RRS. This requirement is referred to in clause 5.11.4 in CSA N290.4-11 as one of several methods of facilitating the human-system interface in the design and, therefore, is still relevant. However, the design Control Room panels for the RRS are clearly organized and labeled, such that colour coding is not required. Therefore this is assessed as an AD with no safety impact. Assessment of this safety principle in Appendix D of this report confirms that Pickering NGS has the SSCs in place to control the reactor power and provide fuel cooling in response to events occurring during startup, shutdown and low power operation. Level 2 defence-in-depth is achieved by detecting deviations from normal operating conditions by the RRS and plant process and control systems. The deviation from control is achieved by the control systems in Pickering NGS that maintain the reactor operating conditions within the normal operating range, and effectively respond to anticipated transients to avoid the need for safety system action. Reactor control in Pickering NGS has a high degree of immunity to process upsets, measurement failures, etc., due to extensive redundancy in control devices and process measurements. The ability to maintain control in the presence of partial system failures, combined with high reliability of the Dual Computer Control System, leads to a very high availability of the Reactor Regulating System, which controls reactor power. There is only one AD associated with this safety principle, and therefore there is no aggregate impact for Safety Principle D-205, Startup, Shutdown and Low Power Operation.

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
D-230 – Preservation of Control Capability	PSR1-AD10	PSR1-AD10 involves requirements for RRS related to Start-up Instrumentation, documentation, reliability, and human-system interface. The Control Rooms in Pickering NGS are designed to remain habitable during normal operation and postulated transients and DBAs. Should a Main Control Room become uninhabitable, the SDSE instrument rooms in Pickering 1,4 and the Unit Emergency Control Centres in Pickering 5-8 are designed to inform operations staff of key plant parameters and allow for critical safety system action to be initiated. There is only one AD associated with this safety principle, and therefore there is no aggregate impact for Safety Principle D-230, Preservation of Control Capability.
O-284 – Operational Limits and Conditions O-278 – Training	PSR1-AD2	PSR1-AD2 involves issues relating to the Human Factors Engineering Program and Verification and Validation during design process. The Pickering B ISR raised a gap on the basis that for smaller modifications, explicitly documenting each validation element was not judged necessary. Operating experience and improvements have been incorporated into the processes and design to improve the human-machine interfaces in many areas (e.g., Control Room annunciation upgrades as a result of changes to computer hardware and operator interface). Additionally, training and qualification processes (and certification processes for Control Room staff) for Operations positions ensure that the staff are competent to carry out functions assigned to them. The extensive use of Main Control Room simulators for training and validation of system modifications to assess their impact on other systems and human-machine interfaces provides OPG with a safe means of testing and training operators, thus strengthening the Level 2 defence-in-depth barrier. There is only one AD associated with these safety principles, and therefore no aggregate impact for Safety Principle O-284, Operational Limits and Conditions, or Safety Principle O-278, Training.

Overall AD Aggregation for Defence-in-Depth Level 2
The two PSR2 ADs assigned to Level 2 defence-in-depth, GI-31-AD1 and GI-44-AD1, are being addressed via the REGDOC-2.4.1 Implementation Plan for extended operation. The ADs are assessed to be low safety significance. The effects of the these ADs are mitigated by the robust engineered features of the control system that prevent deviation from control, a strong management system and well trained operating personnel. PSR1-AD2 involves issues relating to Human Factors Engineering Program and Verification and Validation during the design process. Operating experience and improvements that have been incorporated into the processes and design to improve the human-machine interfaces in many areas and the extensive use of Main Control Room simulators for training and validation of system modifications to assess their impact on other systems and human-machine interfaces provides OPG with an effective means of training and testing operators, thus strengthening the Level 2 defence-in-depth barrier. PSR1-AD10 involves requirements for RRS related to Start-up Instrumentation, documentation, reliability, and human-system interface. Level 2 defence-in-depth is achieved by detecting deviations from normal operating conditions by the Reactor Regulating System and plant process and control systems. Reactor control in Pickering NGS has a high degree of immunity to process upsets, measurement failures, etc., due to extensive redundancy in control devices and process measurements. The two PSR2 ADs and the two PSR1 AD groups have some elements in common, e.g., Human Factors elements appear in both of the PSR2 ADs. Overall, however, the issues associated with the ADs are sufficiently distinct and lack overlap, such that the aggregate effect has no impact on safety. Therefore, the overall aggregate impact of all of the ADs associated with Level 2 defence-in-depth is assessed to be negligible.

AD Aggregation for Defence-in-Depth Level 3

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
D-158 – General Basis for Design	GI-31-AD2 GI-39-AD1 GI-44-AD1 GI-44-AD8	The following ADs are assigned to Safety Principle D-158. • GI-31-AD2 concerns consideration of CSA N288.2-14 requirements for safety analysis using the ADDAM code. The ADDAM 1.4.2 code is being used in the update of the Pickering Safety Report Common Mode Events appendices, under the REGDOC-2.4.1 Implementation Plan for extended operation. As the REGDOC-2.4.1 Implementation Plan does not identify other updates of the Pickering Safety Reports' analyses to address changes in N288.2-14, the existing Safety Report analyses related to atmospheric dispersion and dose calculations continue to support the safety case for Pickering NGS. Also, ADDAM has been evaluated against the 2014 version of CSA N288.2 under a COG Project outside of PSR2. The section by section review showed that no major modifications to the ADDAM 1.4.2 code, methodology or manuals would be required [COG report ISTO-15-5057, *Assessment of Impact of CSA N288.2-14 on ADDAM*, March 2017]. On this basis, the issue is assessed as low safety significance (Safety Significance Level 3). • GI-39-AD1 involves legacy Real-Time Process Computing (RTPC) applications. OPG has a RTPC program in place that adequately deals with both legacy and new RTPC software installations in a manner that meets the intent of the CSA standard CSA-N290.14 and other standards (e.g., ISO/IEC). The OPG program document N-PROG-MP-0006, *Software*, identifies the processes and overall requirements for an effective Software Program that supports safe and efficient plant operation and that meets the intent of CSA-N290.14 and other standards. All OPG Nuclear software installations are subject to the OPG Software Program documents. The legacy software applications have decades of successful service, which indicates the adequacy of the current OPG approach and the programmatic implementation. Evaluation of the legacy software installations with respect to the N290.14-15 requirements is not practicable and would provide very little safety benefit. On this basis, this AD is assessed as very low safety significance (Safety Significance Level 4), and does not contribute to aggregation for this level of defence-in-depth. • GI-44-AD1 involves meeting REGDOC-2.5.2 requirements and limits for AOOs, DBAs and BDBAs. With the current deterministic analyses, dose limits for event sequences are as defined in the Licence Conditions Handbook [LCH-PNGS-R005, *Licence Conditions Handbook*, Pickering Nuclear

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		Generating Station, Effective Date: November 7, 2016] (for single failure and dual failure sequences) and OPG is compliant with those requirements as demonstrated through the accident analyses in the Pickering Safety Reports. The DBA events bound the AOO sequences in terms of system response and consequences. In addition, the Pickering NGS PSAs consider a full range of event sequences – covering AOO-type events, DBAs and BDBAs. Pickering NGS meets its required risk-based Safety Goals as demonstrated through the PSAs. Furthermore, the REGDOC-2.4.1 Implementation Plan for the extended operation will be updated in accordance with the Licence Conditions Handbook and will identify any changes required to support the continued safe operation of Pickering NGS. These changes will be informed by the timeline of the Darlington REGDOC-2.4.1 Implementation Plan and the limited additional years of Pickering NGS operation. Additional practicable enhancements to further address this gap are not readily evident, and would provide limited safety benefit. On this basis, and given the low safety significance (Safety Significance Level 3), this is assessed as an AD and no further action will be taken. • GI-44-AD8 concerns operator action time credits. REGDOC-2.5.2 requirements for allowable times for operator action from the MCR or the field are more limiting than the corresponding requirements of REGDOC-2.4.1. The Pickering A and B Safety Report credits for operator actions from the MCR and in the field are consistent with REGDOC-2.4.1 requirements of 15 and 30 minutes, respectively. The ability to execute required actions within these time limits has been demonstrated through decades of operation, through effective training and testing programs. The gap against the corresponding REGDOC 2.5.2 requirements is a low safety significance issue and has been addressed to the extent practicable. Therefore, it is assessed as a low safety significance issue and no further action is planned. GI-31 addresses conformance with the safety significant requirements of REGDOC-2.4.1. For the purposes of this aggregation assessment, no additional enhancements to the OPG REGDOC-2.4.1 implementation plan are credited beyond those in the current plan. The Level 3 defence-in-depth aspect of GI-44-AD1 involves the requirements for DBAs, as well as for Level 3 mitigation of AOOs. GI-39-AD1 does not interact with any of the other ADs. There is interaction between GI-44-AD1, GI-44-AD8 and GI-31-AD2; that is, a change in operator action time credits (GI-44-AD8) could potentially affect predicted barrier conditions following DBAs (GI-44-AD1) and dose results calculated by ADDAM (GI-31-AD2). However, this interaction does not pose an aggregate impact for extended operation as it is already considered in the dispositioning of these ADs via the REGDOC-2.4.1

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		Implementation Plan for the extended operation. Therefore, the aggregate impact on defence-in-depth of these ADs is assessed to be very low.
D-182 – Equipment Qualification	PSR1-AD1 PSR1-AD16	The following ADs are assigned to Safety Principle D-182, • PSR1-AD1 involves requirements for seismic-qualification. The following issues in PSR1-AD1 were raised in the Darlington and Pickering B ISRs. In terms of Safety Analysis, CSA N289.2 does not identify any specific requirements relating to the seismic success path. It is focused on a systematic approach to identifying the seismic hazard. As such, there are no specific clauses relating to Safety Analysis. However, it is recognized that the magnitude and frequency of the spectra impacts on the qualification of SSCs and that if their required qualification were to change, the success path may need to change. The Darlington ISR raised a gap against Clause 5.5.2.1 of CSA N289.3 because the time histories are not statistically independent. The issues in PSR1-AD1 generally relate to the seismic design report of DNGS structures not explicitly accounting for effects due to • soil-structure interaction (SSI), • the difference between modeling techniques and analysis approaches for the evaluation of the site response analysis for the free-field case, and • complete interaction versus the sub-structure technique for the soil/foundation/structure system. These issues are also applicable to Pickering NGS. The Periodic Inspection of the concrete structures and routine leakage tests of the Containment envelope verify that there is no significant deterioration in the integrity of the Concrete Containment Structures. The rationale for considering gaps related to seismic qualification as an AD is that the seismic PRA confirms that Pickering NGS conforms to CNSC S-294 and to various international guides on seismic PRA, and that the results are acceptable. Consequently these ADs are considered to have no impact on the seismic resistance of qualified structures. This AD group is therefore deemed to have no impact on this aggregation assessment. • PSR1-AD16 Requirements for Containment Coatings and Coverings. The gaps included in this issue concern non-metallic coatings and liners that perform a safety function, such as preserving the concrete Containment envelope. The basic requirement is that not only should

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		these materials be carefully selected, and applied, but their deterioration (especially under post-accident conditions) should not impair the performance of other safety functions, such as blocking of ECI strainers. The seismic issues covered by PSR1-AD1 regarding soil-structure interactions and the issues covered by PSR1-AD16 regarding environmental qualification of non-metallic coatings and liners have nothing in common. Hence there is no aggregation effect.
D-150 – Design Management	PSR1-AD15 PSR1-AD19	These AD groups assigned to Safety Principle D-150, Design Management, have also been assessed under D-150 for their impact on Level 1. • PSR1-AD15 involves safety-related requirements for plant design. This AD group relates to Single Failure Criterion issues that were raised against IAEA NS-R-1 and CNSC RD-337 and assessed as ADs. The PSR2 review of REGDOC-2.5.2, which adopts principles from NS-R-1 and supersedes CNSC RD-337, included a detailed assessment of PSR1 ADs. Also, the PSR2 assessment of CSA N290.2-11, *Requirements for Emergency Core Cooling Systems of Nuclear Power Plants*, identified an AD for the Pickering 1,4 ECI system, which contains singleton components required to operate for the system to operate successfully, on the basis that all practical modifications were made to the Pickering 1,4 ECI system during Pickering A Return to Service and the system meets its unavailability target. Pickering NGS design permits testing, maintenance and other necessary activities to be completed while keeping the system available. This issue is addressed in the Pickering B Continued Operations Plan on the basis that the Level 1 and Level 2 PSA demonstrate that the existing plant design satisfies all safety requirements. The applicability of the gap resolution and subsequent disposition is considered to be equally applicable to Pickering 1,4, where the PSAs have similarly been updated [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014]. Therefore, the issue related to this group of ADs is assessed to be low safety significance. • PSR1-AD19 involves deterministic safety analysis requirements. The ADs in this group are related to dual trip parameter coverage, the criterion for no dry-out for the first trip, the allowable duration of post dry-out operation for the second trip and interpretation of the acceptance criteria relating to the acceptable duration of post dry-out operation. The derived acceptance criteria outlined in COG report [COG-13-9035*, Derived Acceptance Criteria For Deterministic Safety Analysis*, November 2014] are less restrictive than those outlined in the current Pickering 1,4 and Pickering 5-8 Safety Reports, providing confidence that the derived

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		acceptance criteria documented in COG-13-9035 will not adversely impact on existing margins as demonstrated in the Safety Reports. PSR2 confirmed that the PSR1 AD rationale for PSR1-AD19 continues to remain applicable and is not impacted by extended operation. The ADs in group PSR1-AD15 relate to the design features of the Special Safety Systems to perform their safety function when required. The Level 1 and Level 2 PSA demonstrate that the existing plant design satisfies the relevant safety requirements [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014]. The ADs in group PSR1-AD19 relate to the acceptance criteria for the acceptable duration of post dry-out operation. It has been confirmed that the derived acceptance criteria will not adversely impact on existing margins as demonstrated in the Safety Reports. There is no interaction between the two group of ADs associated with D-150 in Level 3 defence-in-depth.
D-186 – Inspectability of Safety Equipment	GI-16-AD1	GI-16-AD1 involves inspection requirements for inaccessible areas, and is also assessed under O-305. This AD group is related to concessions in the Periodic Inspection Plans for where components are deemed inaccessible. The CNSC has accepted the reasonableness of the solution to this issue and has determined that the revised PIPs satisfactorily meet the requirements of CSA N285.5-08 Update No. 1 standard. Furthermore, as indicated in the resolution for GI-16-AD1 in Appendix B of this report, where the inspection of a system or component would necessitate the dismantling of equipment, the required inspection should be performed when the equipment is dismantled for other reasons (i.e., maintenance). There is only one AD associated with this safety principle, and therefore there is no aggregate impact for Safety Principle D-186, Inspectability of Safety Equipment.
D-227 – Monitoring of Plant Safety Status	GI-34-AD1 GI-35-AD1 GI-36-AD2 GI-44-AD2 GI-48-AD1 GI-48-AD2	The following ADs are assigned to Safety Principle D-227. • GI-34-AD1 concerns remote tripping and monitoring capability. Clause 4.1.8.2 of CSA N290.1-13 is for a new plant and requires remote tripping and monitoring capability for both Shutdown Systems. Remote tripping capability is available for Pickering 5-8 SDS2 and Pickering 1,4 SDSE. However, Pickering 5-8 and Pickering 1,4 do not have remote tripping and monitoring capability for SDS1 or SDSA respectively.

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		However, there is dedicated remote tripping and monitoring capability at Pickering 1,4 for SDSE and at Pickering 5-8 for SDS2, and this meets the CSA N290.1 intent and requirements to the extent practicable. In addition, the failure to shutdown probability, as demonstrated in the PSAs [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014], is very low. • GI-35-AD1 involves Human Factors requirements for the Main Control Rooms. The Darlington ISR identified a gap against Clause 4.14.10 of N290.0-11 as a result of minimal design standards related to HFE or HFE activities being formally documented when the Control Rooms were originally designed and constructed. The original design phase of Pickering NGS recognized the need for focus on the operator interfaces in the control centres, and on recognition of the integrated whole of the control centre and the related human-systems interfaces. Pickering NGS, as a result, has decades of safe operation and operating experience with monitoring, operation, testing, maintenance and training (including simulators). With regards to plant modifications, all plant modifications are required to be completed in compliance with OPG Program, [N-PROG-MP-0001-R015, *Engineering Change Control*, May 12, 2017] which includes the requirements for Human Factors and Ergonomics to be considered in design. The technical, design and operator reviews, during and following the design process and via the Availability for Service process, ensure the usability requirements will be achieved. Based on the extensive operating experience and modifications processes, there is no justification for revisiting the overall Control Room design from a Human Factors perspective. On this basis, and as per the very low safety significance (Safety Significance Level 4) this is assessed as an AD and no further action will be taken. • GI-36-AD2 is an issue of monitoring ECI strainer condition. This issue is related to monitoring of ECI System debris strainer effectiveness. Pickering A and B comply with the requirements for new plant debris interceptors, with the exception of clause 5.14.11, for which the benefit of developing and implementing new instrumentation for post-accident effectiveness is assessed to be small. The intent of the requirement is met by monitoring ECI recovery pump performance and reactor building water level. Given the effectiveness of the ECI recovery phase with the installed strainer modules, this issue is assessed as low safety significance (Safety Significance Level 3).

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		• GI-44-AD2 deals with Human Factors requirements for design. Refer to the assessment for GI-35-AD1 above. • GI-48-AD1 involves Clause 7.2.1.13 of CSA N293-13 that states: "Electrical conductors... shall be capable of performing their intended functions for not less than 1 hour after the start of a fire." Modifications to the Fire Protection System meet the requirements by the use of Edwards System Technology (EST) that connects the fire alarm control panels via a data communication link with dual redundant circuit wiring paths. An assessment of the Pyrotronics detection/alarm system was completed [P-CORR-03680-0620819, Re: Resolution Plan for Pickering Periodic Safety Review 2 (PSR2) Global Issue #GI-48 Gap SF1-4, June 20, 2017], and concluded that the characteristics of this detection/alarm system (detection prior to potential alarm system fire damage, and signal latching function) as well as the physical separation in the equipment/cabling configuration, ensure that lack of a one hour fire rating for cabling in these systems would not cause failure to detect the fire or loss of the fire signal once detected. As such, manual suppression of the fire by Emergency Response Team personnel would not be impeded and there is no adverse nuclear safety impact. Therefore, this issue is assessed as an AD with low safety significance (Safety Significance Level 3). • GI-48-AD2 involves Clause 7.2.1.10.1 of CSA N293-12 that states: "A display and control centre shall be located in the MCR [Main Control Room]… capable of providing detailed information on the location and nature of the signal. In addition, the panel operator shall be able to control the fire alarm system without having to leave his or her station." An assessment of this issue was completed [P-CORR-03680-0620820, *Re: Resolution Plan for Pickering Periodic Safety Review 2 (PSR2) Global Issue #GI-48 Gap SF1-3*, June 2, 2017]. The assessment confirmed that the existing arrangement of annunciation/display (including a Fire Control Panel located immediately outside the MCR and annunciation within the MCR), together with emergency response protocols and staff training, meets the intent of the requirement in providing timely response to fire signals. This is a low safety significance issue (Safety Significance Level 3) and has been addressed to the extent practicable. Therefore, it is assessed as an AD. There is interaction among these ADs. However, the issue in GI-36-AD2 is a specific ECI monitoring requirement, whereas the other three ADs are more general in scope. Therefore, GI-36-AD2 does not significantly impact the more general ADs. GI-35-AD1 and GI-44-AD2 deal with the same Human Factors issue and therefore do not involve an aggregate impact. Remote tripping and monitoring provisions (GI-

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		34-AD1) meet the CSA N290.1 intent, and therefore the interaction with the Human Factors ADs is very low. GI-48-AD1 and GI-48-AD2 are related to annunciation and monitoring for fire related issues, however the assessments have confirmed that sufficient mitigation and alternate means are in place to ensure timely response to internal fires. Therefore, the aggregate impact on defence-in-depth of these ADs is assessed to be very low.
O-305 – Maintenance, Testing and Inspection	GI-16-AD1 GI-18-AD1	The following ADs are assigned to Safety Principle O-305. • GI-16-AD1 involves inspection requirements for inaccessible areas. Refer to the assessment for GI-16-AD1 under D-186, Inspectability of safety equipment • GI-18-AD1 is related to CSA N287.7-08 clause 7.11.2 on the accuracy requirement for dew point temperature measurement and repeatability requirement for pressure transmitter measurements related to Containment leak rate testing. Current instrumentation does not meet the accuracy requirement for dew point temperature of ± 1 °C and for pressure transmitter measurement repeatability of ± 0.001% of full scale. Currently industry standard instrumentation can meet ± 2 °C for dew point temperature accuracy, and ± 0.05% full scale for pressure transmitter measurement repeatability. A CSA committee is working to update CSA N287.7 to account for accuracy and repeatability capability of standard available commercial sensors. Until such time as CSA N287.7 is revised, OPG will continue to request appropriate concessions from the CNSC when leak rate testing is required, as per the very low safety significance (Safety Significance Level 4). There is no interaction between inspection of inaccessible areas and dew point temperature measurement accuracy and repeatability. Therefore, the aggregate impact on defence-in-depth of these ADs is assessed to be negligible.
O-284 – Operating Limits and Conditions O-278 – Training	PSR1-AD2	PSR1-AD2 concerns CSA N290.1 Human Machine Interface Consideration in Design, specifically issues relating to Staffing, the Human Factors Engineering Program and Verification and Validation during design process. The Pickering B ISR raised a gap on the basis that for smaller modifications, explicitly documenting each validation element was not judged necessary. Operating experience and improvements have been incorporated into the processes and design to improve the human-machine interfaces in many areas (e.g., Control Room annunciation upgrades as a result of changes to computer hardware and operator interface). Additionally, training and qualification

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		processes (and certification processes for Control Room staff) for Operations positions ensure that the staff are competent to carry out functions assigned to them. The extensive use of Main Control Room simulators for training and validation of system modifications to assess their impact on other systems and human-machine interfaces provides OPG with a safe means of testing and training operators on abnormal and accident operating conditions, thus strengthening the Level 3 defence-in-depth barrier. There is only one AD associated with these safety principles, and therefore there is no aggregate impact for Safety Principle O-284, Operating Limits and Conditions, or Safety Principle O-278, Training.
D-200 – Automatic Shutdown Systems	GI-14-AD1 GI-33-AD1 GI-34-AD1 GI-44-AD6 PSR1-AD5	The following ADs and AD groups are assigned to Safety Principle D-200. • GI-14-AD1 involves revision of the Environmental Qualification Assessment of Tefzel cables to reflect the change of qualified life of the Vertical Flux Detectors. OPG is actively progressing revision of the EQA for Tefzel cables outside of PSR2 to align with the requirements of [N-PROC-RA-0044, *Environmental Qualification Assessment* October 17, 2014] with respect to the Pickering 5-8 Vertical Flux Detector Tefzel cables. Since this issue is in progress and the gap will be addressed, this AD is not assessed any further. • GI-33-AD1 concerns legacy code Class 3 Liquid Injection Shutdown System (LISS) components. This is a legacy design issue. A limited number of LISS components that should have been code Class 1 were purchased and installed as code Class 3. However, a rationale was accepted and a code classification concession was granted by the CNSC to allow the system to remain as-is for the legacy modifications. OPG provided rationale to show that consequences following any failure of Class 3 or Class 6 portions of the systems continue to satisfy the requirements of CSA N285.0. Components have been operating for a very long time and continue to perform their required function. On this basis, this issue is low safety significance (Safety Significance Level 3). • GI-34-AD1 concerns remote tripping and monitoring capability. Clause 4.1.8.2 of CSA N290.1-13 is for a new plant and requires remote tripping and monitoring capability for both Shutdown Systems. Remote tripping capability is available for Pickering 5-8 SDS2 and Pickering 1,4 SDSE. However, Pickering 5-8 and Pickering 1,4 do not have remote tripping and monitoring capability for SDS1 or SDSA, respectively. However, there is dedicated remote tripping and monitoring capability at Pickering 1,4 for SDSE and at Pickering 5-8 for SDS2, and this meets the CSA N290.1 intent and requirements to the extent

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		practicable. In addition, the failure to shutdown probability, as demonstrated in the PSAs, is very low [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014]. • GI-44-AD6 involves reliability requirements for safety systems. Clause 7.6 of REGDOC-2.5.2 requires all safety systems and their support systems to be designed to meet an on-demand failure rate less than 10^{-3} yrs/yr. This requirement is not met for several systems including Pickering 1,4 ECI. However, safety system performance is closely scrutinized and monitored, and established unavailability targets and performance of all safety systems are monitored and reported annually in the Annual Risk and Reliability Report [P-REP-09051.1-00016-R000, *Pickering NGS – 2016 Annual Risk and Reliability Report*, March 31, 2017]. The current engineered provisions provide sufficient functionality to ensure compliance with PSA Safety Goals. This is a low safety significance issue (Safety Significance Level 3). • PSR1-AD5 concerns CSA N290.1 requirements for separation and independence of the Shutdown Systems. The design principles in the N290.1-80 requirements that could not be fully complied with were requirements for independent Shutdown Systems with conceptually different reactivity components, and diverse trip parameters. SDSA and SDSE in Pickering 1,4 are independent trip logic components of the reactor protective system. These two Shutdown Systems are designed to be physically and operationally independent of each other and process systems. They are diverse in design to the extent that their logic components are supplied by different manufacturers. SDSE in Pickering 1,4 provides further defence-in-depth through increased Shutdown System reliability, trip coverage, reactivity depth, and protection against common-mode cross-link effects, such that the overall Shutdown System effectiveness approaches that normally attributed to reactors having two completely separate and independent Shutdown Systems. For the Pickering 1,4 Shutdown System, there are approved exceptions for SDSA and SDSE not being independent of each other. The AD rationale was accepted by the CNSC and the basis for the acceptability of the exception continues to be applicable and is not impacted by operation beyond 2020. GI-34-AD1 is independent of the other ADs and does not interact with them. GI-14-AD1 and GI-33-AD1

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		are also independent and do not interact; however, both of these ADs have a limited interaction with Shutdown System reliability (GI-44-AD6). The aggregate impact is mitigated by the fact that OPG is actively progressing GI-14-AD1, and that a code classification concession was granted by the CNSC based on the rationale provided by OPG (GI-33-AD1). PSR1-AD5 involves reliability and redundancy design-related requirements. In general, these requirements do not interact directly with the other ADs. PSR1-AD5 represents diverse aspects of Shutdown System design that do not directly interact with the other ADs. Therefore, the aggregate impact on Defence-in-Depth of these ADs is assessed to be very low.
D-207 – Emergency Heat Removal	GI-36-AD1 GI-36-AD2 GI-38-AD1 GI-44-AD6 GI-44-AD7 GI-44-AD9 PSR1-AD6 PSR1-AD16	The following ADs and AD groups are assigned to Safety Principle D-207. • GI-36-AD1 involves ECI design requirements based on the least effective Shutdown System. Clause 5.2.1.2 of CSA N290.2-11 requires that ECI System design requirements be based on the assumption that the least effective of the Shutdown Systems has operated successfully. This requirement cannot be met for Pickering 1,4 since there is only one Shutdown System (albeit with tripping capability from separate SDSA and SDSE logic). This issue is related to ECI System capability with respect to Shutdown System operation. The ECI System capability is assessed using the available SDS and hence this meets the CSA N290.2 requirement to the extent practicable. The Pickering 1,4 ECI system reliability meets the licensing target, as demonstrated in [P-REP-09051.1-00016-R000, *Pickering NGS - 2016 Annual Risk and Reliability Report*, March 31, 2017]. On this basis, this is a low safety significance issue (Safety Significance Level 3). • GI-36-AD2 is an issue of monitoring ECI strainer condition. Clause 5.14.11 of CSA N290.2-11 requires instrumentation to be available to monitor post-accident effectiveness and to determine the extent of plugging of ECI System debris interceptors (strainers). While the relative health of a strainer can be inferred by a combination of ECI System recovery pump performance and reactor building water level, there is no direct correlation between these conditions and debris loading available. A detailed assessment [NK30-CORR-00531-05194 R001, *Pickering B – Generic Action Item 06G01 Emergency Core Cooling System Strainer Deposits – Status Update and Request for Closure*, June 30, 2009] of the potential sources of strainer debris and contaminants for Pickering 5-8 demonstrated sufficient margin to ensure post-accident ECI recovery strainer effectiveness. The issues identified in the Pickering 1,4 assessment [NA44-CORR-00531-06062 R000, *GAI 06G01: Emergency Core*

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		Cooling System Strainer Deposits – Status Update, June 30, 2009] resulted in the installation of new strainer modules in Pickering 1,4. Since Pickering 1,4 and Pickering 5-8 comply with the requirements for new plant debris interceptors, with the exception of clause 5.14.11, the benefit of developing and implementing new instrumentation for post-accident effectiveness is assessed to be small. This is because although no direct measurement instrumentation is available to monitor post-accident effectiveness and to determine the extent of plugging of the debris interceptor, the intent of the requirement is met by monitoring ECI recovery pump performance and reactor building water level. Additional mitigating factors include (a) the demonstrated margin that ensures post-accident effectiveness of the ECI recovery phase with the installed strainer modules, (b) the low contribution of ECI System recovery strainer plugging to the PSA results [NA44-CORR-33350-0265268-R000, *Pickering A Risk Assessment ECI Strainer Plugging Following a Large LOCA*, September 23, 2008], and (c) mandatory inspections to ensure the ECI recovery flowpath is free from debris prior to restart of a Pickering 5-8 or Pickering 1,4 unit following a maintenance outage [NK30-SRS-E-082-R004, *ECI Recovery Flowpath Inspection*, March 27, 2014], [NA44-SRS-E-026-U14-R019, *ECI Recovery Flowpath Inspection*, February 21, 2017]. Given the low safety significance (Safety Significance Level 3), this is assessed as an AD and no further action will be taken. • GI-38-AD1 involves unavailability targets for the Shutdown Cooling System and other heat removal systems. Clause 5.6.1 of CSA N290.11-13 requires design reliability to be established for outage heat sinks. Design reliability requirements have not been established individually for all normal and back-up heat sinks used at Pickering NGS. The reliability of all outage heat sinks (including those without explicit targets) is managed under the Risk & Reliability Program [N-PROG-RA-0016-R009, *Risk and Reliability Program*, May 27, 2016] (both through unavailability models as well as through Probabilistic Safety Assessment [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014]), hence reactor safety impact is assessed and monitored. The reactor safety impact of not having explicit individual heat sink design reliability is assessed, monitored and is not a significant issue, and is assessed as Safety Significance Level 4. • GI-44-AD6 involves reliability requirements for safety systems. Clause 7.6 of REGDOC-2.5.2 requires all safety related systems to be designed to meet an on-demand failure rate less than 10^{-3} yrs/yr. However, safety system performance is closely scrutinized and monitored, and established

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		unavailability targets of all safety systems are monitored and reported annually in the Annual Risk and Reliability Report. The current engineered provisions provide sufficient functionality to ensure compliance with PSA Safety Goals [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan,* April 30, 2014]. This is a low safety significance issue (Safety Significance Level 3). • GI-44-AD7 involves sharing of ECI and Containment. Sharing of Safety Systems and Turbine Hall: Clause 7.6.5 of REGDOC-2.5.2 has a new requirement that precludes sharing of safety systems and the turbine generator building. Pickering units share ECI and Negative Pressure Containment, as well as the turbine hall. The main impacts of sharing of ECI and Containment are addressed since if either ECI or Containment is unavailable, all affected units are considered impaired and must be shut down within specified time limits, hence reducing the risk of a coincidental DBA. Moreover environmental conditions in the common turbine building have been assessed and credited provisions have been protected to ensure the ability to shutdown/control, cool and monitor remains available on non-accident units. Required Safety Goals are met. This is a low safety significance issue (Safety Significance Level 3). • GI-44-AD9 involves REGDOC-2.5.2 requirements for ECI Heat Exchanger Leak Detection. Detection/Isolation of ECI Heat Exchanger (HX) Tube Leak: Clause 8.5 of REGDOC-2.5.2 requires ECI recovery heat exchanger tube leak detection capability. Pickering 5-8 ECI recovery heat exchangers do not have leak detection capability on the cooling water side. Pickering 5-8 has ECI recovery piping, pumps and heat exchangers outside of Containment. Components penetrating and outside Containment are all DBE qualified and Nuclear Class 2. Since the intent of leakage detection is served by the system leakage collection, recovery and radiation monitoring in the vicinity, the added benefit of implementing a design modification for direct leakage detection is a low safety significance issue (Safety Significance Level 3). • PSR1-AD6 involves requirements for independence and redundancy in the design of the Emergency Core Cooling System. The issues associated with these ADs are specific to Pickering 1,4. The Pickering 1,4 ECI system utilizes the Moderator system in its low pressure mode, and a number of instances of single failure existed in the design of the ECI system. The issues were assessed as ADs based on the improvements made to the design to reduce the commonality between the Moderator system and ECI

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		recovery, and some of the significant singletons were addressed by design changes. These design changes resulted in the greatest reduction in core damage frequency. Therefore, this is not a safety significant issue and is assessed as a low significance AD. • PSR1-AD16 Requirements for Containment Coatings and Coverings. The gaps included in this Issue concern non-metallic coatings and liners that perform a safety function, like preserving the concrete Containment envelope. The basic requirement is that not only should these materials be carefully selected, and applied, but their deterioration (especially under post-accident conditions) should not impair the performance of other safety functions, such as blocking of ECI strainers. A detailed assessment [NK30-CORR-00531-05194 R001, *Pickering B – Generic Action Item 06G01 Emergency Core Cooling System Strainer Deposits – Status Update and Request for Closure*, June 30, 2009] of the potential sources of strainer debris and contaminants for Pickering 5-8 demonstrated sufficient margin to ensure post-accident ECI recovery strainer effectiveness. The issues identified in the Pickering 1,4 assessment [NA44-CORR-00531-06062 R000, *GAI 06G01: Emergency Core Cooling System Strainer Deposits – Status Update*, June 30, 2009] resulted in the installation of new strainer modules in Pickering 1,4. Pickering 1,4 and Pickering 5-8 comply with the requirements for new plant debris interceptors, and given the low safety significance (Safety Significance Level 3), this is assessed as an AD. All of these ADs involve the ECI system except for GI-38-AD1 and therefore the latter has negligible interaction with the other ADs. GI-44-AD9 has negligible interaction with the other ADs as it is specific to HX tube leakage. GI-36-AD1 and GI-36-AD2 both deal with ECI performance; however, the strainer performance is not a function of the Shutdown System assumed in the design, so there is no interaction between these ADs. Safety system separation (GI-44-AD7) is normally addressed separately from design for reliability (GI-44-AD6), and therefore their interaction is very low. PSR1-AD6 involves requirements for independence and redundancy in the design of the Emergency Core Cooling System, which does not interact with the other ADs. PSR1-AD16 involves Requirements for Containment Coatings and Coverings which relates to performance of ECI recovery system following a postulated event. The synergy between the ADs is minimal and therefore, the aggregate impact on defence-in-depth of these ADs is assessed to be very low.
D-217 –	GI-42-AD1	The following ADs and AD groups are assigned to Safety Principle D-217.

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
Confinement of Radioactive Material	GI-44-AD6 PSR1-AD3 PSR1-AD4 PSR1-AD7 PSR1-AD8	• GI-42-AD1 involves requirements for examination and testing of Concrete Containment Structures. The Concrete Containment Structures (CCSs) at Pickering A and B were built and tested to meet the 1965 and 1970 National Building Code of Canada requirements, respectively, prior to the initial issuance of CSA N287.5. No assessments exist which demonstrate that the requirements in effect during construction of Pickering NGS CCSs comply with the requirements of CSA N287.5. A PSR2 gap was raised for Pickering NGS given that conformance with the specific requirements of CSA N287.5 has not been demonstrated. The original Pickering construction included requirements for tests and quality control procedures which generally meet the intent of CSA N287.5. The controls in place at the time of construction and the ongoing controls in place for inspections, aging management and modifications adequately meet the intent of CSA N287.5-11. Ongoing confirmation that the Pickering NGS CCSs remain fit for service is demonstrated via periodic and in-service inspections conducted in accordance with the requirements of CSA N285.5 and CSA N287.7, and the resultant inspection reports attest to the quality of the design. The Engineering Change Control process ensures that that any design changes made to the Pickering CCSs will comply with CSA N287.5 going forward, as applicable. The residual elements of this issue are of low safety significance. • GI-44-AD6 involves reliability requirements for safety systems. Refer to assessment for GI-44-AD6 against D-207, Emergency heat removal. • PSR1-AD3 involves general requirements for the design of Concrete Containment Structures. These ADs involve general requirements for the design of Concrete Containment Structures. The original and subsequent revisions of the CSA N287 series of standards were issued after completion of design and construction of Pickering NGS. Therefore the details related to general requirements of Containment structure, parts, materials, design, fabrications, construction, inspection examination, testing and commissioning in accordance with the series of standards of CSA N287 were not available. At that time, the CCSs were designed to meet the requirements of the National Building Code (NBC). All CSA N287.1-93 (R2004) Pickering B ISR Review findings were assessed to be ADs in PSR1 given robust design practices at the time, together with ongoing periodic inspections and in-service testing. The standards that applied during the original construction of Pickering NGS included requirements for tests and quality control procedures to ensure that the concrete used in the as-built structures met

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		the original design requirements. The PSR2 review of CSA N287.1-14 also outlines Programs, Procedures and Standards which are credited with the ability to detect and monitor any safety significant degradation mechanisms and thus to provide assurance of continued fitness for service of the Pickering NGS CCSs. • PSR1-AD4 involves specific requirements for the design of Concrete Containment Structures. These ADs involve specific requirements for the design of CCSs. This group of ADs applies to initial construction, installation, and fabrication of mechanical splices for Concrete Containment Structures. The original and subsequent revisions of the CSA N287 series of standards were issued after completion of design and construction of Pickering NGS. All CSA N287.3-93 (R2004) Pickering B ISR Review findings were assessed to be ADs in PSR1 given robust design practices at the time, together with ongoing periodic inspections and in-service testing. The standards that applied during original construction of Pickering NGS included requirements for tests and quality control procedures to ensure that the concrete used in the as-built structures met the original design requirements. The PSR2 review of CSA N287.3-14 also outlines Programs, Procedures and Standards which are credited with the ability to detect and monitor any safety significant degradation mechanisms and thus to provide assurance of continued fitness for service of the Pickering NGS CCSs. • PSR1-AD7 involves requirements for Containment pressure capability in operation and to respond to accidents. Clause 3.4.2 of CNSC R-7 identifies that the negative design pressure of Containment must not be greater than that predicted in the Safety Report for a set of postulated events with failure of dousing. It was not considered necessary to evaluate event combinations involving failure of dousing for negative Containment design pressure impacts, because these event combinations result in higher rather than lower Containment pressure. Clause 3.4.2 identifies that the negative design pressure of Containment must not be greater than that predicted in the Safety Report for a set of postulated events with failure of dousing. It is not necessary to evaluate event combinations involving failure of dousing for negative Containment design pressure impacts, because these event combinations result in higher rather than lower Containment pressure. Therefore, the intent is met. • PSR1-AD8 involves requirements for Containment related to Containment leakage. These PSR1 ADs involve requirements for Containment related to Containment leakage and the fact

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		that only a positive pressure proof test was performed for Pickering NGS A. and, as required, a negative pressure test was not performed during commissioning. This requirement is not met because the Containment envelope was not tested to the lowest predicted negative pressure following an accident. However, the negative design pressure is limited due to the multi-unit design of the Pickering Containment and the PSR1 review demonstrates that leakage is not expected to be significant at these pressures. Examination and testing of CCSs (GI-42-AD1) contributes to confidence in the reliability of Containment (GI-44-AD6). Therefore, there is interaction between these two ADs, although it is not direct as they involve different activities. The general requirements for the CCSs (PSR1-AD3) primarily impact the Containment performance (e.g., leak-tightness) and are of lower significance for Containment reliability. This is also true for PSR1-AD4. PSR1-AD7 and PSR1-AD8 are diverse requirements which do not significantly interact among each other or the other ADs assessed for this safety principle. Therefore, the aggregate impact on Safety Principle D-217 of these ADs is assessed to be very low.
D-221 – Protection of Confinement Structure	PSR1-AD9	The following AD group is assigned to Safety Principle D-221. • PSR1-AD9 involves hydrogen monitoring requirements related to BDBAs. Clause 10.2.3 of CSA N290.3-11 states: "New builds shall monitor the conditions identified according to the requirements of Clause 10.2.2 [... (e.g., pressure, temperature, and hydrogen concentration inside Containment) that need to be monitored for BDBAs ...]" The absence of hydrogen monitoring instrumentation is acceptable, given installed hydrogen mitigation equipment together with SAMGs provide means to safely manage any hydrogen in Containment. This issue is considered to be an AD since the Post-LOCA Hydrogen Ignition System has been environmentally qualified for a mission time of 30 days, and would therefore likely be available for hydrogen mitigation in the short term following a LOCA plus loss of ECI. The PARS (Passive Auto-Catalytic Recombiners) are designed to consume long term hydrogen. There is only one AD associated with this safety principle, and therefore there is no aggregate impact for Safety Principle D-221, Protection of Confinement Structure.
D-174 –	GI-44-AD6	The following AD and AD group are assigned to Safety Principle D-174.

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
Reliability Targets	PSR1-AD11	• GI-44-AD6 involves reliability requirements for safety systems. Refer to the assessment for GI-44-AD6 against D-207, Emergency heat removal. • PSR1-AD11 Requirements for Electrical Power and Instrument Air Systems The gaps in AD#191 in PSR1-AD11 were raised because the practice used at Pickering 'A' was to provide a single rectifier for each Class I battery. This is considered acceptable since rectifier failures are annunciated and the associated battery has a 45 minute capacity, which allows time for operator action. Provision is made to connect a temporary charger if the main charger is out of service for long periods. Per Regulatory Document RD-98, reliability targets are set for Systems Important to Safety. The Class I power system is in the list of Systems Important to Safety and therefore it is a monitored system required to meet its reliability target. Since the reliability of the system has been demonstrated to be acceptable with its current design, the Acceptable Deviation remains applicable for extended operation. There is overlap between GI-44-AD6 and PSR1-AD11 in that both ADs are related to reliability requirements, but for different systems, and therefore there is no aggregate impact of these ADs on D-174 – Reliability Targets. Therefore, the aggregate impact on defence-in-depth of these ADs is assessed to be very low.
D-177 – Dependent Failures	PSR1-AD1 PSR1-AD18 PSR1-AD21	The following AD groups are assigned to Safety Principle D-177. • PSR1-AD1 involves issues relating to assessing seismicity at the Pickering NGS site. Seismic PSAs [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014] have been issued for both Pickering 1,4 and Pickering 5-8 and confirm that Pickering NGS conforms to CNSC S-294 and to various international guides on seismic PRA. Consequently these gaps are considered to have no impact on the seismic resistance of qualified structures. The periodic inspection of the concrete structures and routine leakage tests of the Containment envelope verify that there is no significant deterioration in the integrity of the Concrete Containment Structures. • PSR1-AD18 involves safety-related requirements for hazards (turbine orientation and firewater supply). AD #243: The orientation of the turbine generators relative to the safety related SSCs at Darlington

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		NGS does not meet the requirement of CNSC RD-337. Turbine Failures at Pickering NGS are addressed in the PSA Hazard Screening addressed in the PSR2 Hazard Analysis Safety Factor Report. The Darlington ISR D278 issue resolution, which concluded that reactor can be safely shut down, cooled down and maintained subcritical following a postulated turbine disintegration, is also applicable to Pickering NGS. The effect of turbine missiles has been considered in the supporting design analysis. • PSR1-AD21 involves measures to prevent the spread of fire as well as to ensure staff safety and capability to respond. The scope of this AD group originated with deviations between the design of Darlington NGS and requirements of the NBCC-2005. For example, a new Article in NBCC-2005 calls for integrated testing of fire protection and life safety systems to ensure that they will operate together, as intended. However, documentation could not be found to confirm that an integrated systems test is performed for the life safety and fire protection systems installed at Darlington NGS. The gaps associated with this AD group were assessed as an AD for PSR2 based on the following key arguments: • Fire Hazard Analysis (FHA) and the Fire Safety Shutdown Analysis (FSSA) demonstrate that the safety objectives of Pickering 1,4 and 5-8 are met under postulated fire scenarios. • In the event of a fire at Pickering NGS, personnel, as per training and as instructed via the public address system, are to avoid the incident unit and area as well as to refrain from using the elevators. • Access to Pickering NGS is limited to trained personnel who are familiar with the hazards and safety features of site buildings. Multiple means of egress are available and existing signage is clearly recognizable and understood by the personnel accessing the Station buildings. • Although there is a lack of smoke detection near the entrance to certain areas of the Station, it unlikely that these fires would go undetected and unreported given the plant is served by multiple alternate means of egress. • With respect to electrical conductors, there are no high-rise buildings, areas of refuge, or contained use areas located at Pickering NGS. • Although the absence of electronic supervision for fire protection water supply valves could result in a valve being closed without sending an alert to central alarm monitoring, water supply valves without electronic supervision are locked in an 'open' position at Darlington which would prevent

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		unintended closure. As per Section 11.3 of Appendix B of [NA44-DM-71400-00002 R000 *Design Manual for Pickering Generating Station, Fire Protection Systems*, February 2014] for Pickering 1,4 and Section 4.2 of [NK30-DM-71400-00001-R006, *Design Manual for Pickering Nuclear, Fire Protection System*, January 2016] for Pickering 5-8, the same holds true for Pickering NGS as well. As discussed under the PSR2 review for NFPA 24 [P-REP-03680-00029-R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 1, 5, 6, and 7*, March 2, 2017], a number of yard post indicator valves at Pickering NGS without electronic supervision do not have locking mechanisms. Resolution of this finding is currently in progress with locks now installed on the majority of the affected valves. This was identified as a PSR2 gap under the NFPA 24 review (PSR2 NFPA 24 Gap #1). Therefore, the ADs applicable to Darlington are also applicable to Pickering NGS with one exception, which is being tracked as a PSR2 gap. PSR1-AD1 is related to seismic resistance of qualified structures. PSR1-AD18 is related to the orientation of the turbine generators relative to the safety related SSCs. PSR1-AD21 is involves measures to prevent the spread of fire as well as to ensure staff safety and capability to respond. As can be observed, there is no synergy among the three AD groups and therefore, there is no aggregate impact of these ADs on D-177, Dependent Failures.
M&C-246 – Safety Evaluation of Design	PSR1-AD15 PSR1-AD19	The following AD groups are assigned to Safety Principle M&C-246. • PSR1-AD15 involves safety-related requirements for plant design. This AD group relates to Single Failure Criterion issues that were raised against IAEA NS-R-1 and CNSC RD-337 and assessed as ADs. The PSR2 review of REGDOC-2.5.2, which adopts principles from NS-R-1 and supersedes CNSC RD-337, included a detailed assessment of PSR1 ADs. As stated in the PSR2 code review for REGDOC-2.5.2 [P-REP-03680-00029-R000, *Pickering PSR2 Law, Regulation, Code and Standard Reviews Associated with Safety Factors 1, 5, 6, and 7,* March 2, 2017], this issue was transferred to the Pickering B Continued Operations Plan, where it was closed on the basis that the Level 1 and Level 2 PSA demonstrate that the existing plant design satisfies relevant safety requirements. The applicability of the gap resolution and subsequent disposition is considered to be equally applicable to Pickering 1,4, where the PSAs have similarly been updated.

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		Therefore, this issue is of low safety significance. • PSR1-AD19 involves deterministic safety analysis requirements. The ADs in this group are related to dual trip parameter coverage, the criterion for no dry-out for the first trip, the allowable duration of post dry-out operation for the second trip and interpretation of the acceptance criterion relating to the acceptable duration of post dry-out operation. However, the derived acceptance criteria outlined in the COG report [COG-13-9035, *Derived Acceptance Criteria For Deterministic Safety Analysis*, November 2014], developed by the industry taking into account feedback from the CNSC, are less restrictive than those outlined in the current Pickering 1,4 and Pickering 5-8 Safety Reports, providing confidence that the derived acceptance criteria documented in COG-13-9035 will not adversely impact on existing margins as demonstrated in the Safety Reports. The PSR2 confirmed that the PSR1 AD rationale for PSR1-AD19 continues to remain applicable and is not impacted by extended operation. The ADs in this group that relate to Safety Principle M&C-246, Safety Evaluation of Design, have no significant interaction because the issues are not cumulative in nature and individual groups have very low safety significance or safety impact. Also, these ADs are related to issues which, for the most part, have been addressed to minimize any potential risk to plant operation. Therefore, the overall conclusion for Safety Principle M&C-246 is that the aggregate impact on defence-in-depth of these ADs is negligible.
S-136 – External Factors Affecting the Plant	GI-13-AD1 GI-13-AD2 GI-13-AD3 GI-13-AD4 GI-43-AD1 PSR1-AD1	The following ADs and AD groups are assigned to Safety Principle S-136. GI-13-AD1: This AD is related to the CSA N289.3 requirements to confirm that a) the generated time history used within seismic analyses of safety-related systems correctly represents the design ground response spectrum for the Pickering site in compliance with CSA N289.3-10, and b) the power spectral density (PSD) function of each time-history has been calculated and shown to not have any significant gaps in energy over the frequency intervals. The rationale for considering this gap as an AD is the time-history method is a typical method for seismic qualification that has been employed at Pickering NGS. Time-history ground motion inputs at Pickering NGS were established based on the requirements of CSA N289.3-M81 and that the seismic analysis method is conservative and adequate, which is confirmed by the Pickering Seismic PRA that concludes the seismic design of systems and structures are sound. Consequently these gaps are considered to have no impact on the seismic resistance of qualified structures. GI-13-AD2: This AD is related to the CSA N289.4-12 requirements for confirmation that aging effects that

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		may impair seismic functionality shall be accounted for in seismic qualification by testing. Routine monitoring measures ensure that degradation effects will not be permitted to advance to the extent that seismic functionality is impaired. OPG's commitment [N-CORR-00531-05661, Design Codes and Standards Effective Dates for OPG Nuclear Fleet, April 2012] to using CSA N289.4-12 for testing procedures for seismic qualification of nuclear power plant SSCs will ensure that the requirements will be followed. Also, administrative controls [N-STD-MP-0025, *General Requirements For Seismic Qualification of OPG Nuclear Facilities*, October 27, 2016] ensure that seismic qualification of SSCs performing safety-related functions during and following an earthquake is maintained for the life of the facility. Consequently this gap is considered to have no impact on the seismic resistance of equipment qualified by test. GI-13-AD3: This AD is related to the CSA N289.5 requirement for seismic monitoring/recording. OPG has installed in-plant seismic instrumentation to monitor seismic activity at Pickering NGS (and at Darlington) in compliance with CSA standard N289.5 [NK30-DM-61150-10001, *Pickering Nuclear: Seismic Monitoring System*, September 2013; N-GUID-02004-10000-R00, Seismic Monitoring of OPG Nuclear Generating Stations, December 2010]. OPG has established procedures - Abnormal Incidents Manuals - that detail station response to earthquakes. Clear responsibilities are established to support monitoring and post-seismic response to an event [NK30-AIM-058-09013-6.0, *Abnormal Incident Manual: Seismic/Common Mode Event*; NA44-AIM-014-09013-06, *Abnormal Incident Manual: Seismic Event*]. OPG is also a contributor to the operation of the Southern Ontario Seismic Network (SOSN) which provides detailed free-field seismic records covering Southern Ontario. These systems support in-plant monitoring of the station's response to seismic events. The intent of the requirements has been met, and for these reasons, and as per the very low safety significance (Safety Significance Level 4), this is assessed as an Acceptable Deviation with no further action. GI-13-AD4 (for Units 1 and 4 only): This AD is related to a requirement in CSA N289.3 for the minimum number of cycles used for seismic fatigue analysis for the level of compliance of Pickering NGS plant structures supporting the operation of Pickering NGS reactors in the context of extended operation. Pickering Units 1,4 Class 1 systems and components are designed to ASME Code Section III which betters the CSA N289.3 requirement, including required cycles for fatigue analysis. Also, Seismic Margin Assessment is an accepted method for assessing seismic qualification and as such, this is an Acceptable Deviation for Pickering 1,4. For continuing analysis of potential new modifications, the requirements of CSA N289.3-10 with regards to number of cycles for seismic fatigue analysis would be met or bettered, consistent with the modelling methodology in place at OPG for such work as noted above. For these reasons, and as per the very low safety significance (Safety Significance Level 4), this is assessed as an

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		Acceptable Deviation for Pickering 1,4 with no further action. GI-43-AD1: This AD is related to a new requirement in CSA N291-15 for bolted connections in members that are part of the seismic load resisting system. The original code requirements for PNGS safety related structures [National Building Code of Canada] and the Seismic Margin Assessments (SMA) include requirements of CSA S16 “Design of Steel Structures”, which is the basis for the requirements for bolted connections of steel structures in CSA N291-15. Given that the SMA methodology and the plant design both include requirements of S16/S16.1 (predecessor of S16), the plant meets or has been assessed to these requirements. As it would not be practicable to make changes to the bolted steel connections in the existing structural design, and given the low safety significance (Significance Level 3), this is assessed as an Acceptable Deviation with no further action. PSR1-AD1 involves requirements for seismic-qualification and testing. The following issues in PSR1-AD1 were raised in the Darlington and Pickering B ISRs. In terms of Safety Analysis, CSA N289.2 does not specify any specific requirements relating to the seismic success path. It is focused on a systematic approach to identify the seismic hazard. As such, there are no specific clauses relating to Safety Analysis. However, it is recognized that the magnitude and frequency of the spectra impacts on the qualification of SSCs and that if their required qualification were to change, the success path may need to change. The Darlington ISR raised a gap against Clause 5.5.2.1 of CSA N289.3 because the time histories are not statistically independent. The issues in PSR1-AD1 generally relate to the seismic design report of DNGS structures not explicitly accounting for effects due to • soil-structure interaction (SSI), • the difference between modeling techniques and analysis approaches for the evaluation of the site response analysis for the free-field case, and • complete interaction versus the sub-structure technique for the soil/foundation/structure system. These issues are also applicable to Pickering NGS. The Periodic Inspection of the concrete structures and routine leakage tests of the Containment envelope verify that there is no significant deterioration in the integrity of the Concrete Containment Structures. The rationale for considering gaps related to seismic qualification as an AD is that the seismic PRA confirms that Pickering NGS conforms to CNSC S-294 and to various international guides on seismic

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		PRA, and that the results are acceptable. Consequently these ADs are considered to have no impact on the seismic resistance of qualified structures. This AD group is therefore deemed to have no impact on this aggregation assessment. GI-13-AD1, GI-13-AD4 and GI-43-AD1 have the same attribute “Seismic Design” insofar as the gaps are all related to the design programs by which the qualified SSCs were designed. While this is a common factor, the seismic design of Pickering NGS has been shown to be conservative such that all qualified SSCs will withstand the effects of a design basis seismic event. The seismic design aspect covered by PSR1-AD1 regarding soil structure interactions and GI-13-AD3 for monitoring have nothing in common with the other ADs with the attribute “Seismic Design”. Hence there is no aggregation effect. The aggregate impacts of these 6 seismic ADs on Pickering NGS seismic design integrity capability is negligible and hence has no impact on public safety.

Overall AD Aggregation for Defence-in-Depth Level 3
The ADs associated with the safety principles in Level 3 defence-in-depth include the following diverse areas: • D-158 – General Basis for Design – Four PSR2 AD groups were assessed under this safety principle. The ADs are related to deterministic safety analysis. Although there may be some interaction among the ADs in this area, this interaction does not pose an aggregate impact for extended operation as some of the issues have largely been addressed, are in progress or are already considered in the dispositioning of these ADs via the REGDOC-2.4.1 Implementation Plan for extended operation. • D-182 – Equipment Qualification – There are two AD groups associated with this Safety Principle. The seismic issues covered by PSR1-AD1 regarding soil-structure interactions and the issues covered by PSR1-AD16 regarding environmental qualification of non-metallic coatings and liners have nothing in common. Hence there is no interaction between the two ADs. • D-150 – Design Management – The two ADs associated with this safety principle have no interaction because the issues are against unique SSCs, and individual groups have low or very low safety significance or safety impact. OPG's Design Management Program, N-PROG-MP-0009, specifies requirements for procurement engineering processes ensuring implementation and maintenance of the nuclear facilities meet the design basis requirements. The Design Management Program provides assurance that design and procedure changes are prepared, reviewed, approved, documented and implemented in accordance with approved procedures, applicable regulatory requirements, standards and industry practices. • D-186 – Inspectability of Safety Equipment – There is only one AD associated with this safety principle. GI-16-AD1 involves inspection requirements for inaccessible areas. The CNSC has been informed and has found the current method in the program that provides for alternate means of assessing condition of the SSCs to be acceptable. • D-227 – Monitoring of Plant Safety Status – There is some interaction among the ADs assessed in this safety principle. One AD relates to monitoring of the ECI strainer condition, whereas the other ADs are more general in scope and are related to Human Factors issues and the ability for remote tripping and monitoring provisions. The ADs related to fire detection and monitoring are assessed to be of low safety significance due to the mitigations and the alternate means available for detection to ensure timely response to internal fires. The assessment confirms that the mitigations in place are adequate to provide the necessary defence-in-depth for control of events within design basis. • O-305 – Maintenance, Testing and Inspection – ADs involve inspection requirements for inaccessible areas and dew point temperature measurement accuracy and repeatability. The CNSC has been informed and has found the current method in the program that provides for alternate means of assessing condition of the SSCs to be acceptable. The issue related to the dew point temperature measurement is being addressed at an industry level in consultation with the relevant CSA committee. Both issues are considered to be of very low safety significance. • O-284 – Operating Limits and Conditions – The ADs assessed in this safety principle are related to human-machine interface considerations in design. Operating experience and improvements have been incorporated into the processes and design to improve the human-machine interfaces in many areas (e.g., Control Room annunciation upgrades as a result of changes to computer hardware and

Overall AD Aggregation for Defence-in-Depth Level 3
operator interface). • O-278 – Training – The same ADs that are assessed for O-284 are also assessed for O-278 with respect to Training. The review confirms that training and qualification processes (and certification processes for Control Room staff) for Operations positions ensure that the staff are competent to carry out functions assigned to them. In addition extensive use of Main Control Room simulators for training and validation of system modifications to assess their impact on other systems and human-machine interfaces provides OPG with a safe means of testing and training operators on abnormal and accident operating conditions, thus strengthening the Level 3 defence-in-depth barrier. • D-200 – Automatic Shutdown Systems – PSR1-AD5 involves reliability and redundancy design-related requirements. GI-34-AD1, related to remote tripping and monitoring capability, is independent of the other ADs and does not interact with them. GI-14-AD1, Environmental Qualification Assessment of Tefzel cables, and GI-33-AD1, legacy code classification of LISS components, are also independent and do not interact; however, both of these ADs have a limited interaction with Shutdown System reliability (GI-44-AD6). The aggregate impact is mitigated by the fact that OPG is actively progressing the GI-14-AD1 activity outside of PSR2, and that a code classification concession was granted by the CNSC based on the rationale provided by OPG (GI-33-AD1). In general, these requirements do not interact directly with the other ADs. • D-207-Emergency Heat Removal – All of these ADs involve the ECI system except for GI-38-AD1, which involves unavailability targets for the Shutdown Cooling System and other heat removal systems, and therefore the latter has negligible interaction with the other ADs. The Pickering 1,4 ECI system reliability meets the licensing target, as demonstrated in [NA44-REP-09051.1-00014, *2014 Annual Reliability Report – Pickering Units 1 & 4*, March 2015] and Level 1 and Level 2 PSA demonstrated that the existing plant design satisfies all safety requirements. • D-217 – Confinement of Radioactive Material – The ADs associated with this safety principle are related to Concrete Containment Structures. Pickering A and B were built and tested to meet the 1965 and 1970 National Building Code of Canada requirements, respectively, prior to the initial issuance of CSA N287.5. The original Pickering construction included requirements for tests and quality control procedures which generally meet the intent of N287.5. The controls in place at the time of construction and the ongoing controls in place for inspections, aging management and modifications adequately meet the intent of CSA N287.5-11. Ongoing confirmation that the Pickering NGS Concrete Containment Structures remain fit for service is demonstrated via periodic and in-service inspections conducted in accordance with the requirements of CSA N285.5 and N287.7, and the resultant inspection reports attest to the quality of the design. • D-221 – Protection of Confinement Structure – The ADs associated with this safety principle relate to hydrogen monitoring requirements for BDBAs. This issue is considered to be an AD since PLHIS has been environmentally qualified for a mission time of 30 days, and the PARS (Passive Auto-Catalytic Recombiners) are designed to consume long term hydrogen. • D-174 Reliability Targets – The ADs associated with this safety principle relate to requirements for Reliability Targets due to lack of required redundancy in some systems. As required by CNSC Regulatory Document RD/GD-98, Reliability Program, OPG has developed the lists of Systems Important to Safety for Pickering 1,4 and 5-8. The Systems Important to Safety, along with their unavailability targets

Overall AD Aggregation for Defence-in-Depth Level 3
are documented in P-REP-09051.1-00016 R000, *Pickering NGS - 2016 Annual Risk and Reliability Report*. Therefore, there is no significant safety issue associated with this safety principle. • D-177 – Dependent Failures – The ADs associated with this safety principle relate to common mode failures, such as seismic events. Seismic PRAs have been issued for both Pickering 1,4 and Pickering 5-8 and confirm that Pickering NGS conforms to CNSC S-294 and to various international guides on seismic PRA. Consequently these gaps have no impact on the seismic resistance of qualified structures. Also, the Periodic Inspection of the concrete structures and routine leakage tests of the Containment envelope verify that there is no significant deterioration in the integrity of the Concrete Containment Structures • M&C-246 – Safety Evaluation of Design – The ADs associated with this safety principle relate to requirements for redundancy, independence and separation, and trip effectiveness. The Level 1 and Level 2 PSA for Pickering NGS demonstrate that the existing plant design satisfies all safety requirements and the industry-supported, derived acceptance criteria documented in [COG-13-9035*, Derived Acceptance Criteria For Deterministic Safety Analysis*, November 2014] will not adversely impact on existing margins as demonstrated in the Safety Reports. • S-136 – External Factors Affecting the Plan – The ADs associated with this safety principle involve requirements for seismic-qualification and testing. Seismic PRAs have been issued for both Pickering 1,4 and Pickering 5-8 and confirm that Pickering NGS conforms to CNSC S-294 and to various international guides on seismic PRA. Consequently these issues have no impact on the seismic resistance of qualified structures. The ADs associated with the Safety Principles D-158, D-150, D-186, D-227, O-305, O-284, D-200, D-207, D-217, D-221, D-174, D-177, D-182, S-136, M&C-246, O-278 in Level 3 defence-in-depth cover diverse areas with no significant interactions. The aggregate impact of the ADs for each safety principle is determined to have no significant impact on safety. Furthermore, the overall aggregate impact of all of the ADs associated to Level 3 defence-in-depth is assessed to be low The dominant issues observed for Level 3 defence-in-depth are related to the design requirements for redundancy, independence and separation of Special Safety Systems. However, these issues do not interact sufficiently to aggregate or have significant safety impact. The issues are mitigated by ongoing confirmation that the Pickering NGS SSCs remain fit for service as demonstrated via periodic and in-service inspections. Implementation and execution of Pickering NGS's Equipment Reliability Program, N-PROG-MA-0026, is identified as a Strength. Confirmation of the effectiveness of the program is Pickering NGS Systems Important to Safety meeting the reliability targets [P-REP-09051.1-00016 R000, *Pickering NGS - 2016 Annual Risk and Reliability Report,* March 31, 2017]). In addition, Level 1 and Level 2 PSAs demonstrate that the existing plant design satisfies all safety requirements.

AD Aggregation for Defence-in-Depth Level 4

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
D-158 – General Basis for Design	GI-44-AD1 GI-44-AD3 GI-44-AD4	The following ADs are assigned to Safety Principle D-158. • GI-44-AD1 involves meeting REGDOC-2.5.2 requirements and limits for AOOs, DBAs and BDBAs. • GI-44-AD3 involves seismic margin requirements for Beyond Design Basis Earthquake. • GI-44-AD4 involves meeting REGDOC-2.5.2 Safety Goals. The Level 4 defence-in-depth aspect of GI-44-AD1 involves the requirements for BDBAs. GI-44-AD1 and GI-44-AD3 primarily affect calculated BDBA consequences and frequencies, whereas GI-44-AD4 deals with the safety criterion. Therefore, there is very low interaction between GI-44-AD4 and the other two ADs. Seismic analysis is included in the PSA and the REGDOC-2.4.1 Implementation Plan for deterministic safety analysis, so GI-44-AD3 has an interaction with GI-44-AD1; however, GI-44-AD3 can be considered as an aspect of the more general GI-44-AD1 that is also more fully addressed in GI-13 in the context of CSA N289 requirements. Therefore, the aggregate impact on defence-in-depth of these ADs is assessed to be very low.
D-207 – Emergency Heat Removal	GI-36-AD1 GI-36-AD2 GI-38-AD1 GI-44-AD6 GI-44-AD7 GI-44-AD9 PSR1-AD6 PSR1-AD16	The AD groups assigned to Safety Principle D-207, Emergency Heat Removal, have also been assessed for their impact on Level 3. The following AD groups are assigned to Safety Principle D-207. • GI-36-AD1 involves ECI design requirements based on the least effective Shutdown System. Clause 5.2.1.2 of CSA N290.2-11 requires that ECI System design requirements be based on the assumption that the least effective of the Shutdown Systems has operated successfully. This requirement cannot be met for Pickering 1,4 since there is only one Shutdown System (albeit with tripping capability from separate SDSA and SDSE logic). This issue is related to ECI System capability with respect to Shutdown System operation. The ECI System capability is assessed using the available SDS and hence this meets the CSA N290.2 requirement to the extent practicable. The Pickering 1,4 ECI system reliability meets the licensing target, as demonstrated in [P-REP-09051.1-00016-R000, *Pickering NGS - 2016 Annual Risk and Reliability Report*, March 31, 2017]. On this basis, this is a low safety significance issue (Safety Significance Level 3). • GI-36-AD2 is an issue of monitoring ECI strainer condition.

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		Clause 5.14.11 of CSA N290.2-11 requires instrumentation to be available to monitor post-accident effectiveness and to determine the extent of plugging of ECI System debris interceptors (strainers). While the relative health of a strainer can be inferred by a combination of ECI System recovery pump performance and reactor building water level, there is no direct correlation between these conditions and debris loading available. A detailed assessment [NK30-CORR-00531-05194 R001, *Pickering B – Generic Action Item 06G01 Emergency Core Cooling System Strainer Deposits – Status Update and Request for Closure*, June 30, 2009] of the potential sources of strainer debris and contaminants for Pickering 5-8 demonstrated sufficient margin to ensure post-accident ECI recovery strainer effectiveness. The issues identified in the Pickering 1,4 assessment [NA44-CORR-00531-06062 R000, *GAI 06G01: Emergency Core Cooling System Strainer Deposits – Status Update*, June 30, 2009] resulted in the installation of new strainer modules in Pickering 1,4. Since Pickering 1,4 and Pickering 5-8 comply with the requirements for new plant debris interceptors, with the exception of clause 5.14.11, the benefit of developing and implementing new instrumentation for post-accident effectiveness is assessed to be small. This is because although no direct measurement instrumentation is available to monitor post-accident effectiveness and to determine the extent of plugging of the debris interceptor, the intent of the requirement is met by monitoring ECI recovery pump performance and reactor building water level. Additional mitigating factors include (a) the demonstrated margin that ensures post-accident effectiveness of the ECI recovery phase with the installed strainer modules, (b) the low contribution of ECI System recovery strainer plugging to the PSA results [NA44-CORR-33350-0265268-R000, *Pickering A Risk Assessment ECI Strainer Plugging Following a Large LOCA*, September 23, 2008], and (c) mandatory inspections to ensure the ECI recovery flowpath is free from debris prior to restart of a Pickering 5-8 or Pickering 1,4 unit following a maintenance outage [NK30-SRS-E-082-R004, *ECI Recovery Flowpath Inspection*, March 27, 2014], [NA44-SRS-E-026-U14-R019, *ECI Recovery Flowpath Inspection*, February 21, 2017]. Given the low safety significance (Safety Significance Level 3), this is assessed as an AD and no further action will be taken. • GI-38-AD1 involves unavailability targets for the Shutdown Cooling System and other heat removal systems. Clause 5.6.1 of CSA N290.11-13 requires design reliability to be established for outage heat sinks. Design reliability requirements have not been established individually for all normal and back-up

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		heat sinks used at Pickering NGS. The reliability of all outage heat sinks (including those without explicit targets) is managed under the Risk & Reliability Program [N-PROG-RA-0016-R009, *Risk and Reliability Program*, May 27, 2016] (both through unavailability models as well as through Probabilistic Safety Assessment [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan*, April 30, 2014]), hence reactor safety impact is assessed and monitored. The reactor safety impact of not having explicit individual heat sink design reliability is assessed, monitored and is not a significant issue, and is assessed as Safety Significance Level 4. • GI-44-AD6 involves reliability requirements for safety systems. Clause 7.6 of REGDOC-2.5.2 requires all safety related systems to be designed to meet an on-demand failure rate less than 10^{-3} yrs/yr. However, safety system performance is closely scrutinized and monitored, and established unavailability targets of all safety systems are monitored and reported annually in the Annual Risk and Reliability Report. The current engineered provisions provide sufficient functionality to ensure compliance with PSA Safety Goals [P-REP-03611-00006-R00, *Pickering NGS PSA Update to Include Enhancements from the Fukushima Integrated Action Plan,* April 30, 2014]. This is a low safety significance issue (Safety Significance Level 3). • GI-44-AD7 involves sharing of ECI and Containment. Sharing of Safety Systems and Turbine Hall: Clause 7.6.5 of REGDOC-2.5.2 has a new requirement that precludes sharing of safety systems and the turbine generator building. Pickering units share ECI and Negative Pressure Containment (NPC), as well as the turbine hall. The main impacts of sharing of ECI and Containment are addressed since if either ECI or Containment is unavailable, all affected units are considered impaired and must be shut down within specified time limits, hence reducing the risk of a coincidental DBA. Moreover environmental conditions in the common turbine building have been assessed and credited provisions have been protected to ensure the ability to shutdown/control, cool and monitor remains available on non-accident units. Required Safety Goals are met. This is a low safety significance issue (Safety Significance Level 3). • GI-44-AD9 involves REGDOC-2.5.2 requirements for ECI Heat Exchanger Leak Detection. Detection/Isolation of ECI Heat Exchanger (HX) Tube Leak: Clause 8.5 of REGDOC-2.5.2 requires

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		ECI recovery heat exchanger tube leak detection capability. Pickering 5-8 ECI recovery heat exchangers do not have leak detection capability on the cooling water side. Pickering 5-8 has ECI recovery piping, pumps and heat exchangers outside of Containment. Components penetrating and outside Containment are all DBE qualified and Nuclear Class 2. Since the intent of leakage detection is served by the system leakage collection, recovery and radiation monitoring in the vicinity, the added benefit of implementing a design modification for direct leakage detection is a low safety significance issue (Safety Significance Level 3). • PSR1-AD6 involves requirements for independence and redundancy in the design of the Emergency Core Cooling System. The issues associated with these ADs are specific to Pickering 1,4. The Pickering 1,4 ECI system utilizes the Moderator system in its low pressure mode, and a number of instances of single failure susceptibility existed in the design of the ECI system. The issues were assessed as ADs based on the improvements made to the design to reduce the commonality between the Moderator system and ECI recovery, and some of the significant singletons were addressed by design changes. These design changes resulted in the greatest reduction in calculated core damage frequency. Therefore, this is not a safety significant issue and is assessed as a low significant AD. • PSR1-AD16 Requirements for Containment Coatings and Coverings. The gaps included in this Issue concern non-metallic coatings and liners that perform a safety function, such as preserving the concrete Containment envelope. The basic requirement is that not only should these materials be carefully selected, and applied, but their deterioration (especially under post-accident conditions) should not impair the performance of other safety functions, such as blocking of ECI strainers. All of these ADs involve the ECI system except for GI-38-AD1 and therefore the latter has negligible interaction with the other ADs. GI-44-AD9 has negligible interaction with the other ADs as it is specific to HX tube leakage. GI-36-AD1 and GI-36-AD2 both deal with ECI performance; however, strainer performance is not a function of the Shutdown System credited in the safety analysis, so there is no interaction between these ADs. Safety system separation (GI-44-AD7) is normally addressed separately from design for reliability (GI-44-AD6), and therefore the interaction of these two ADs is very low. PSR1-AD6 involves requirements for independence and redundancy in the design of the Emergency Core Cooling System, which does not interact with PSR1-AD16, which involves Requirements for Containment Coatings and Coverings which relates to performance of ECI recovery system following a

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		postulated event. The synergy between the ADs is minimal and therefore, the aggregate impact on defence-in-depth of these ADs is assessed to be very low.
AM-326 – Engineered Features of Accident Management	PSR1-AD12	PSR1-AD12 involves requirements for post-accident monitoring design. The Pickering NGS design satisfies requirements for providing essential monitoring capability via built-in redundancy and qualification. Routine maintenance and calibration procedures in conjunction with redundant information chains and environmentally qualified sensors and cables ensure availability. In this way a need for immediate post-accident maintenance or calibration is minimized. Nevertheless, should a component fail, it may not be immediately repairable, depending on the component's location and the accident scenario. An assessment of the impact of this gap was provided in OPG Report [NK30-REP-03680-00016 R000, *OPG Response To CNSC Comments On Pickering NGS-B Integrated Safety Review-Plant Design, Safety Analysis, Safety Performance, Ageing And Equipment Qualification*, September 22, 2009]. It was concluded that there were sufficient instrument loops that would be accessible post-accident, there was sufficient redundancy and that calibrations for accuracy during post-accident mission were not necessary. Given the similarities between plant design and instrument loop locations, this item is also an AD for Pickering 1,4 There is only one AD, and therefore there is no aggregate impact for AM-326.
D-217 – Confinement of Radioactive Material	GI-44-AD5 PSR1-AD4	The following AD and AD group are assigned to Safety Principle D-217: • GI-44-AD5 involves a requirement for Containment leak-tightness for a period sufficient to implement off-site emergency measures. The requirement for Containment leak tightness for a period sufficient to implement off-site emergency measures cannot be explicitly demonstrated since an explicit set of BDBAs is not identified within the licensing basis. The current engineered provisions provide a sufficient Containment barrier to ensure compliance with existing Safety Goals. Beyond Design Basis provisions using Emergency Mitigating Equipment and SAMG provide additional means of protecting Containment integrity against potential accident sequences. Risk improvement initiatives continue to be developed to further mitigate this issue. Furthermore, due to the nature of the Pickering NGS design and construction, it is not practicable to retrofit a leak tightness barrier for a period sufficient to implement off-site emergency measures following certain BDBAs. This is a low

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
		safety significance issue (Safety Significance Level 3) and is being managed to the extent practicable. Therefore, it is assessed as an AD. • PSR1-AD4 involves specific requirements for the design of Concrete Containment Structures. The ADs associated with this group involve specific requirements for the design of Concrete Containment Structures. This group of ADs applies to initial construction, installation, and fabrication of mechanical splices for Concrete Containment Structures. The original and subsequent revisions of CSA N287 series of standards were issued after completion of design and construction of Pickering NGS. All N287.3-93 (R2004) Pickering B ISR Review findings were assessed to be ADs in PSR1 given robust design practices at the time, together with ongoing periodic inspections and in-service testing. The standards that applied during the original construction of Pickering NGS included requirements for tests and quality control procedures to ensure that the concrete used in the as-built structures met the original design requirements. The PSR2 review of N287.3-14 also outlines Programs, Procedures and Standards which are credited with the ability to detect and monitor any safety significant degradation mechanisms and thus to provide assurance of continued fitness for service of the Pickering NGS CCSs. While the two issues in this assessment are related to Containment structure design, their impacts are on different aspects of the design. GI-44-AD5 is related to the design requirement for Containment leak-tightness, while the second AD group, PSR1-AD4, is related to verification of the original design and construction. Therefore, there is no aggregate impact of the two ADs assessed under this safety principle.
D-221 – Protection of Confinement Structure	PSR1-AD9	PSR1-AD9 involves hydrogen monitoring requirements related to BDBAs. Clause 10.2.3 of N290.3-11 states: "New builds shall monitor the conditions identified according to the requirements of Clause 10.2.2 [... (e.g., pressure, temperature, and hydrogen concentration inside Containment) that need to be monitored for BDBAs ...] " The absence of hydrogen monitoring instrumentation is acceptable, given installed hydrogen mitigation equipment together with SAMGs provide means to safely manage any hydrogen in Containment. There is only one AD, and therefore no aggregate impact for D-221.
D-227 –	GI-44-AD10	GI-44-AD10 involves REGDOC-2.5.2 requirements for Beyond Design Basis qualification of the Safety

Safety Principle	AD #	Aggregate AD Assessment by Safety Principle
Monitoring of Plant Safety Status		Parameter Display System. The Safety Parameter Display System cannot be demonstrated to be qualified for BDBAs since an explicit set of BDBAs is not identified within the licensing basis. As part of the follow-up to the 2011 Fukushima accident, instrumentation to support critical parameters required to function for BDBAs has been evaluated for survivability in [N-REP-09013-10007 R000, *Ontario Power Generation Severe Accident Management Guidance Instrumentation and Equipment Survivability - Summary Report*, December 13, 2013]. The instrument loops associated with these critical parameters have been identified for use in Critical Safety Parameter Monitoring and BDBA accident management guidelines. The indications from these loops are not in one central location and, in some cases, require field action (e.g., power) to obtain data. The capability to monitor post-accident conditions remotely from the Main Control Room is provided in the SDSE Instrument Rooms for Units 1,4 and in the Unit Emergency Control Centres for Units 5-8. Since the intent of this requirement is met, the added benefit of implementing a design modification addressing this gap is not significant. This is a low safety significance issue and has been addressed to the extent practicable with enhancements already identified in [N-REP-09013-10009, *Information to Support Closure of FAI 1.8.1 - Survivability Assessments for Equipment and Instrumentation for Severe Accident Management*, December 17, 2013]. Therefore, it is assessed as an AD. There is only one AD, and therefore no aggregate impact for D-227.

Overall AD Aggregation for Defence-in-Depth Level 4
The ADs associated with the safety principles in Level 4 defence-in-depth include the following diverse areas: • D-158 – General Design Basis – The AD groups are related to deterministic safety analysis. Although there may be some interaction among the ADs in this area, this interaction does not pose an aggregate impact for extended operation as some of the issues have largely been addressed, are in progress or are already considered in the dispositioning of these ADs via the REGDOC-2.4.1 Implementation Plan for the extended operation. • D-207 – Emergency Heat Removal – All of these ADs involve the ECI system except for GI-38-AD1, which involves unavailability targets for the Shutdown Cooling System and other heat removal systems, and therefore the latter has negligible interaction with the other ADs. The Pickering 1,4 ECI system reliability meets the licensing target, as demonstrated in [P-REP-09051.1-00016-R000, Pickering NGS - 2016 Annual Risk and Reliability Report, March 31, 2017] and Level 1 and Level 2 PSA demonstrate that the existing plant design satisfies all safety requirements. On this basis, and as per the low safety significance of the issues related to the group of ADs assessed in this safety principle, there is no aggregated impact. • AM-326 – Engineered Features of Accident Management – The one AD group assessed in this safety principle involves requirements for post-accident monitoring design. The Pickering NGS design satisfies requirements for providing essential monitoring capability via built-in redundancy and qualification. Routine maintenance and calibration procedures in conjunction with redundant information chains and environmentally qualified sensors and cables ensure availability. • D-217 – Confinement of Radioactive Material – The ADs assessed for this safety principle are related to Concrete Containment Structures. GI-44-AD5 is related to the design requirement for Containment leak-tightness for a period sufficient to implement off-site emergency measures for BDBAs, while the second AD group, PSR1-AD47, is related to verification of the original design and construction which is periodically assessed through inspections and monitoring. The PSR2 review of N287.3-14 also outlines Programs, Procedures and Standards which provide the ability to detect and monitor any safety significant degradation mechanisms and thus to provide assurance of continued fitness for service of the Pickering NGS Concrete Containment Structures. • D-221 – Protection of Confinement - PSR1-AD9 involves hydrogen monitoring requirements related to BDBAs. The absence of hydrogen monitoring instrumentation is acceptable, given installed hydrogen mitigation equipment which together with SAMGs provides means to safely manage hydrogen in Containment. • D-227 – Monitoring of Plant Safety Status – The AD related to this safety principle (GI-44-AD10) involve REGDOC-2.5.2 requirements for Beyond Design Basis qualification of the Safety Parameter Display System. As part of the follow-up to the 2011 Fukushima accident, instrumentation to support critical parameters required to function for BDBAs has been evaluated for survivability in OPG Report [N-REP-09013-10007 R000, *Ontario Power Generation Severe Accident Management Guidance Instrumentation and Equipment Survivability - Summary Report*, December 13, 2013]. This issue is a low safety significance issue and has been addressed to the extent practicable. GI-32 addresses conformance with the safety significant requirements of CNSC REGDOC-2.4.2. For the purposes of this aggregation

Overall AD Aggregation for Defence-in-Depth Level 4
assessment, no additional enhancements to the OPG REGDOC-2.4.2 Implementation Strategy are credited beyond those currently planned. The ADs associated with the safety principles in Level 4 defence-in-depth cover diverse areas with no significant interactions among them. The aggregate impact of the ADs for each safety principle is determined to have no significant impact on safety. Furthermore, the overall aggregate impact of all of the ADs associated to Level 4 defence-in-depth is assessed to be negligible.

AD Aggregation for Defence-in-Depth Level 5

There are no ADs associated with the Safety Principles in Level 5 defence-in-depth.

RIB # 12135

March 2, 2018

Mr. Randy Lockwood
Senior Vice President
Pickering Nuclear
Ontario Power Generation Inc.
1675 Montgomery Park Road, P41, 3G-4
Pickering, ON L1V 2R5

Subject: Pickering NGS: CNSC Staff Acceptance of Pickering NGS Periodic Safety Review 2 (PSR2) Integrated Implementation Plan (IIP), Revision 1

Dear Mr. Lockwood:

Canadian Nuclear Safety Commission (CNSC) staff have completed the review of OPG Integrated Implementation Plan (IIP) R001 [1], the last deliverable under Pickering NGS Periodic Safety Review 2 (PSR2), conducted pursuant to REGDOC-2.3.3 [2]. The initial revision of the IIP [3] was submitted by OPG on November 30, 2017 and was reviewed and commented by CNSC staff [4].

Under the provisions of the CNSC/OPG Protocol [5] for the conduct of PSR in support of Pickering NGS licence renewal, numerous meetings and communication exchanges took place between CNSC staff and OPG, to clarify the regulatory expectations, and receive additional detailed information regarding planned IIP activities and their corresponding target completion dates. In addition, CNSC staff visited the Pickering NGS site on February 14, 2018 to collect information specifically related to measures for containment controlled filtered venting. Furthermore, CNSC staff and OPG met on February 26, 2018 to ensure that the revised IIP is clear, consistent with the PSR2 Global Assessment Report and supported by OPG administrative programs and databases for tracking and reporting.

CNSC staff review of the IIP R001 [1] determined that OPG has satisfactorily dispositioned CNSC staff comments [4] on IIP revision 0 [3] and incorporated sufficient information regarding the actions to be undertaken under IIP R001.

CNSC staff also determined that the IIP, as submitted in [1, 3], fulfils the regulatory requirements of CNSC REGDOC-2.3.3, meets CNSC staff expectations and thus is a satisfactory foundation for plant safety enhancements for the extended operations of Pickering NGS. As such, CNSC staff conclude that Pickering Periodic Safety Review Integrated Implementation Plan [1] is acceptable.

Should you have any questions, please contact Dr. Al Omar at al.omar@canada.ca or at 613-995-0565.

Sincerely,

Alexandre Viktorov, Ph.D.
Regulatory Program Director
Pickering Regulatory Program Division

DR. A. VIKTOROV
Director
Pickering Regulatory Program Division

Canadian Nuclear Safety Commission
280 Slater Street
Ottawa, Ontario
K1P 5S9

Dear Dr. Viktorov:

Pickering NGS Periodic Safety Review 2 – Submission of Integrated Implementation Plan Revision 1

The purpose of this letter is to submit for Canadian Nuclear Safety Commission (CNSC) staff acceptance the Pickering Periodic Safety Review 2 (PSR2) Integrated Implementation Plan (IIP), Report P-REP-033680-00031-R001 (Enclosure 1).

In April 2015, the CNSC informed Ontario Power Generation (OPG) that a Periodic Safety Review (PSR) was required to support extension to commercial operation of Pickering NGS beyond 2020 (Reference 1).

In support of OPG's decision to continue Pickering NGS commercial operation to the end of 2024 (Reference 2), OPG has conducted a PSR which is an internationally recognized process defined in IAEA Specific Safety Guide 25, and regulated in Canada under CNSC REGDOC-2.3.3 – Periodic Safety Reviews.

The objective of Pickering's PSR, referred to as PSR2, as it builds on previous assessments, was to confirm that the design, operation, structures, systems, and components support continued safe operation, and to recommend reasonable and practical safety enhancements to further improve the already low risk of plant operation.

The PSR2 was conducted thoroughly by senior industry experts with different teams independently executing each of the four major phases:

- **PSR2 Basis Document:** A PSR2 Basis Document defining the scope of the PSR2 process, and documenting how the PSR2 was to be conducted was prepared (Reference 3) and accepted by the CNSC (Reference 4) in July 2016.

- **Safety Factor Reviews:** Fifteen Safety Factor and two Complementary Reviews identifying compliances and gaps were completed and submitted for CNSC review in fall 2016 / winter 2017.

- **Global Assessment:** A Global Assessment that consolidated gaps from the Safety Factor and Complementary Reviews into Global Issues with proposed resolutions which were assigned safety significance, prioritized and ranked was completed. The results from the Global Assessment are documented in a PSR2 Global Assessment Report (GAR) submitted (Reference 5) for CNSC review in October 2017. A revision to the GAR was subsequently submitted (Reference 6) in February 2018 and acknowledged by the CNSC that it satisfied requirements of CNSC REGDOC 2.3.3. (Reference 7).

  The Global Assessment concludes that the current Pickering NGS design, operation, processes and management system will ensure continued safe operation of Units 1,4 and 5-8, both in the short term, and for extended operation. The GAR recommends reasonable and practical resolutions that further enhance safety.

- **Integrated Implementation Plan (IIP):** The Pickering PSR2 IIP represents the final step in the comprehensive PSR process which documents the actions with target completion dates that support the reasonable and practical resolutions from the Global Assessment. Revision 0 of the PSR2 IIP was submitted (Reference 8) in November 2017. This revision to the PSR2 IIP incorporates minor enhancements and comments received from the CNSC (References 9) that are dispositioned in Attachment 1.

In accordance with REGDOC 2.3.3, OPG has in place the required organizational structure and administrative instructions for ensuring successful execution of the IIP.

The Pickering PSR2 confirms that there are no safety issues for continued safe operation of the Pickering NGS through 2024, and the actions within this IIP will further enhance safety.

OPG's comprehensive programs are aligned with industry best practices for ensuring the condition of important Structures, Systems and Components are well understood and well maintained. The Pickering PSR2 and the enclosed IIP represents OPG's commitment to continual improvement in plant condition, operation and performance.

If you have any questions, please contact Paulina Herrera, Manager, Pickering Regulatory Affairs at 905-839-1151 extension 3235.

Disposition of CNSC Comments on P-REP-03680-00031-R000

Attachment: Results of CNSC Staff Review of OPG Integrated Implementation Plan, Rev 000 [A1]

#	Page #	Section # / Paragraph # / Figure #	The Issue	CNSC Staff Comments and Recommendations	OPG Dispositions
1.		General		OPG is to disposition remaining CNSC staff comments [A2] on OPG Draft IIP of 3 Nov 2017.	Remaining comments dispositioned.
2.		General		OPG is to consider if some of the TCDs need to be adjusted based on latest available OPG information and discussions with CNSC staff.	TCDs adjusted by OPG on a number of actions with the latest information.
3.		General		OPG is to add some wording in the IIP describing the "Enhancement Value", which is mentioned in detail in the PSR Database	Paragraph summarizing the "Enhancement Value" added to section 3.1.3 of the IIP.
4.		General		OPG is to ensure that the latest revisions to the GAR [A3] are reflected and are consistent with the IIP.	GAR R01 information reflected and is consistent with the IIP.
5.	12	Figure 3	Using 0.00E+00 on the vertical scale is not correct.	Modify the vertical scale and re-configure the figure accordingly.	Figure 3 vertical scale modified to a "log scale" and figure 3 re-configured and updated with data values.
6.	14	1.3.3 Heading	Consistency of expressing "Extended Operation Period"	**Deterministic Safety Analysis to Support ~~Extended Operating Period~~ Operation to the End of 2024 (GI-24)**	Updated to read "**Deterministic Safety Analysis to Support ~~Extended Operating Period~~ Operation to the End of 2024 (GI-24)**"

#	Page #	Section # / Paragraph # / Figure #	The Issue	CNSC Staff Comments and Recommendations		OPG Dispositions
7.	17	2.1 Paragraphs 3 and 4	The statement in paragraph 3, *The review of Safety Factors 1 through 15 and other complementary assessments confirmed that the design, condition and operation of Pickering Units 1, 4 and 5-8 (as well as common systems) will support continued safe operation for the extended operating period,* contradicts the information provided in Section 1.3.2.1 which states that condition assessments must	Until all condition assessments are completed, it is not appropriate to state that the SFR reviews confirmed that the condition of SSCs will support safe operation for the extended operating period. Plus there are activities remaining to confirm the fitness-for-service of fuel channels for the extended operating period. This statement together with the statement in Paragraph 4 in Section 2.1 should be further qualified.	OPG should consider changing the sentence to read " … (as well as common systems) will ~~support~~ ensure continued safe …"	Sentence updated to read " … (as well as common systems) will ~~support~~ ensure continued safe …"

#	Page #	Section # / Paragraph # / Figure #	The Issue	CNSC Staff Comments and Recommendations	OPG Dispositions
			be completed for various components.		
8.	18	1st paragraph	OPG stated that "Furthermore, the Global Assessment confirmed that OPG and Pickering NGS Senior Leadership are committed to investing in the plant, and focusing the organization to strive for continued improvement in the plant condition, operation and performance."	OPG should indicate where in the Global Assessment process as — reported in the GAR — that some analysis was performed the results of which confirmed that "OPG and Senior Leadership" are committed to investing in the plant, and focusing ..."OPG needs to refer to some pages or quotes from the GAR to support this type of statements. Otherwise this sentence should be removed from this section 2.2.	Wording updated to read: "Furthermore, OPG Pickering NGS Senior Leadership is committed to investing in the plant, and focusing the organization to strive for continued improvement in the plant condition, operation and performance." This paragraph moved from Section 2.2 to the end of section 2.2.1.
9.	20 and 21	2.2.3, 1st paragraph, 1st sentence,	It is stated that "Through PSR2, 143 gaps were identified from	Part of the 143 gaps is a sum of 23 Type III Additional Gaps that were identified by CNSC staff. OPG should modify this sentence and make it consistent with the information	Section 2.2.3 modified to make it consistent with the information included in Figure 4 page 16 and more clearly describes where the numbers come from.

#	Page #	Section # / Paragraph # / Figure #	The Issue	CNSC Staff Comments and Recommendations	OPG Dispositions
		and 1st paragraph on page 21	various sources (e.g. Safety Factor Reports, Complementary Assessments and Expert Panel review) and were integrated into the Global Assessment."	included in Figure 4 on page 16. In addition, first paragraph on page 21 has to be reconciled and edited to make the first and second paragraphs of 2.2.3 consistent with Figure 4 on page 16.	
10.	21	Second paragraph	Consistency of expressing "Extended Operation Period"	Replace the 2 occurrences of "extended operation period" with "operation to the end of 2024"	IIP document updated to replace the 2 occurrences of "extended operation period" with "operation to the end of 2024"
11.	22, and elsewhere	3rd paragraph	Consistency of the use of "IIP Administration Instruction"	Here and on pages 23, 25 OPG uses "IIP Administration process", while on page 27 and Reference 14 OPG uses "IIP Administration Instruction "IIP Administration", respectively. OPG should use consistent terminology that is. As well, consistent with the terminology used in OPG's IIP Administration Instruction document. Also, OPG used "IIP administrative and change control process on pages 16 and 114,	IIP document revised to ensure consistent use of the term "IIP Administration Instruction" [R-14] throughout the document as appropriate.
12.	24	Figure 5		The text supporting and describing Figure 5 does not cover all the boxes illustrated in the	Figure 5 showing IIP structure removed from the document. Refer to the IIP Administration

#	Page #	Section # / Paragraph # / Figure #	The Issue	CNSC Staff Comments and Recommendations	OPG Dispositions
				Figure. OPG should complete the description of all the boxes and roles. In addition, OPG should ensure that Figure 5 is consistent with the IIP Administrative Instruction being developed by OPG.	Instruction for figure and description of roles and accountabilities.
13.	25	3.1.3	Consistency of the use of the term "IIP Administration Instruction"	OPG is to ensure consistency between this section 3.1.3 and the "IIP Administration Instruction" being developed by OPG; especially the management of the "IIP change control process mentioned in 2nd paragraph under section 3.1.3. In addition, ensure consistency of the entire section 3.1.3 with the IIP Administration Instruction being developed.	IIP Document revised to remove section 3.1.3. Refer to the IIP Administration Instruction for detailed information regarding execution management and oversight.
14.	27	3.2.2	Consistency with the IIP Administrative Instruction being developed by OPG	OPG to ensure that the contents of Section 3.2.2 are reflected in and consistent with the IIP Administration Instruction being developed by OPG.	IIP Document revised to remove section 3.2.2. Refer to the IIP Administration Instruction for detailed information regarding change control.
15.	39, 69	Appendix A, B	GI-12 was assigned to "06-Fitness for service" SCA, which is not in line with CNSC SCA structure.	According to CNSC SCA structure, Environmental Qualification of Equipment belongs to "Physical Design" SCA. GI-12 should be listed under "SCA 05 Physical Design"	GI-12 SCA will be updated throughout the document to be consistent with SCA 05 Physical Design instead of SCA 06.

#	Page #	Section # / Paragraph # / Figure #	The Issue	CNSC Staff Comments and Recommendations	OPG Dispositions
16.	52	Appendix B	**G01-RS4-06-04** - The scope of this action doesn't explicitly indicate that the Technical Basis Document for the FC LCMP will be updated from that of 2011, as identified under SF2-AG1.	It is proposed to consider making the following changes (indicated in red): Under **G01-RS4-06-04.2**: "Update and Submit 2018 Fuel Channel Life Cycle Management Plan (LCMP), the Technical Basis Document (TBD) used in the FC LCMP, and the Pickering NGS Fuel Channel Readiness Plan in Support of Operation to the end of 2024 (FCRP2024)" Under **Action**: Incorporate the results of the Pickering NGS FCRP2024 activities into Fuel Channel assessments/evaluations and identify actions to mitigate aging effects, as required. Update the FCRP2024, the TBD used in FC LCMP, and the 2018 LCMP accordingly. Under **Completion Criteria**: This action is considered complete when the FCRP2024 (P-PLAN-31100-00002) update, the TBD used in FC LCMP update, and the 2018 Fuel Channel LCMP (N-PLAN-01060-10002) update have been submitted to CNSC.	The submission of the Technical Basis Document will be managed outside of the IIP. No change to the IIP document wording.
17.	69	Appendix B, IIP Action G12-RS1-06-17.1	Action G12-RS1-06-17.1 text states "Assess existing EQAs for Environmentally	To facilitate gauging the successful completion of this action, CNSC staff expect OPG's outputs to include: • The total number of EQAs that need to be assessed	The plan for OPG to address this action are as follows: 1. Assessment of 205 EQAs to identify potential gaps and recommendations

#	Page #	Section # / Paragraph # / Figure #	The Issue	CNSC Staff Comments and Recommendations	OPG Dispositions
			Qualified (EQ) life-limited components to support commercial operation to 2024." The target completion date is 2019-12-31.	• The plan to assess these EQAs, say starting in early 2018, including the number or percentage of EQAs that is planned to be completed in 2018 and 2019.	for updated PNGS end of commercial operations. 2. Upon completion of step 1, updating of EQAs as required to address the gaps and recommendations. Target to have 50 percent completed by end of 2018 and remaining completed in 2019.
18.	79	Appendix B	Wrong reference in the success criteria	Change "N-PROG-RA-0013" to "N-PROG-RA-0016"	Reference changed to "N-PROG-RA-0016"
19.	79	G27-RS2-04-24	**IIP action G27-RS2-04-24 states that:** "Investigate and implement additional practicable design, operational and/or analytical enhancements to further improve Pickering 1, 4 Severe Core Damage	The current description of G27-RS2-04-24 is too general to address specific CNSC staff concerns regarding the demonstration of effectiveness of strategies (e.g. EME, fire water injection, etc.) to show that they can arrest core degradation and ensure in-vessel retention (SF6-AG3). OPG is to include a new action under G27-RS2-04-24 to record the results of the investigation and to address the demonstration of effectiveness of strategies (e.g. EME, fire water injection, etc.) analytically and through exercises/drills to show that they can arrest core degradation	New action added under G27-RS2-04-24 titled "**Investigate additional practicable design, operational and/or analytical enhancements**" which will record the results of the investigation and demonstrate effectiveness. A new action added under G40-RS1-10-28 titled "**Complete reassessment of Pickering NGS Beyond Design Basis Containment Integrity**" To document OPGs plan to submit a letter to address the assessment of options that can be used to mitigate the consequences of a severe accident beyond IVR to ensure the controlled release from the vacuum building.

#	Page #	Section # / Paragraph # / Figure #	The Issue	CNSC Staff Comments and Recommendations	OPG Dispositions
			Frequency and Large Release Frequency (e.g., alternative emergency cooling water makeup)."	and **ensure in-vessel retention (IVR)** in a timely manner (SF6-AG3). In addition, OPG is to include the assessment of options that can be used to mitigate the consequences of a severe accident beyond IVR to ensure the controlled release from the vacuum building.	
20.	116	Item D 3.19	OPG indicates that "The majority (52 of 75) of the AGs were Type I & II (requests for additional information) that will be addressed by OPG before March 15, 2018 [D-6]. None of these AGs invalidate the conclusions of the associated report.	Although this statement is true at the time of developing Rev 0 of the IIP, the results of the preliminary CNSC review [A4] of the AG's may lead to implementation a number of additional IIP actions or the modification of the scope of existing IIP actions to disposition such AGs by OPG.	Comments related to AG's will be discussed and disposition under the matters related to the AGs. No change to the IIP document.

Revision Summary

Revision Number	Date	Comments
R000	2017-11-30	Initial issue. Prepared by RCM Technologies P-REP-03680-00031-R000.
R001	2018-02-28	Final issue. Prepared by OPG incorporating e-Doc 5455745 “CNSC Staff Review of OPG Integrated Implementation Plan (IIP) Rev.000 dated February 13, 2018.”

Executive Summary

The Pickering Nuclear Generating Station has been operated safely by Ontario Power Generation (OPG) for over 40 years. Continuous investments in plant condition, driven by strong reliability programs have enhanced safety and reliability throughout the plant's life. OPG and the leadership team at Pickering remain committed to continued safety and reliability.

In June 2015, the Canadian Nuclear Safety Commission (CNSC) informed OPG that a Periodic Safety Review (PSR) was required to support extension to commercial operation of Pickering NGS beyond 2020.

In support of OPG's plan to extend commercial operation of Pickering NGS to the end of 2024, OPG has conducted a Periodic Safety Review (PSR) which is an internationally recognized process defined in IAEA Specific Safety Guide 25, and regulated in Canada under CNSC REGDOC-2.3.3 – *Periodic Safety Reviews*. The objective of Pickering's PSR, referred to as PSR2 as it builds on previous assessments, was to confirm that the design, operation, structures, systems, and components (SSCs) support continued safe operation, and to recommend reasonable and practicable safety enhancements to further improve the already low risk of plant operation.

This document, Pickering NGS PSR2 Integrated Implementation Plan (IIP), which is submitted to the CNSC for review and acceptance, represents the final step in a comprehensive two-year process that further demonstrates OPG's commitment to safe, reliable operation, and maintaining a healthy nuclear safety culture.

Pickering PSR2 has acknowledged and credited many actions that were already in progress to enhance safety and reliability. The PSR2 review found strength in managed systems and programs. Additional initiatives under existing programs have been identified that will ensure safety and reliability are maintained and enhanced throughout the extended operations period to the end of 2024.

OPG is committed to continuous improvement in safety at all of its nuclear facilities and has robust comprehensive programs in place that are aligned with industry best practices for ensuring the condition of SSCs important to safety is well understood and well maintained. Pickering NGS reactor units will be operated only if fitness for service of SSCs important to safety is assured.

Pickering PSR2 confirms that there are no safety issues that preclude continued safe operation of Pickering NGS through 2024. The actions within this IIP will further enhance safety and reliability.

1.0 OVERVIEW

OPG is responsible for approximately half of the electricity generated in the Province of Ontario, where Pickering Nuclear Generating Station (NGS) supplies 14% of Ontario's electricity needs.

In June 2015, the CNSC informed OPG [R-16] that a PSR would be required to support Pickering NGS commercial operation beyond 2020. As a result, and in support of OPG's decision [R-17] to extend commercial operation of Pickering NGS to the end of 2024, OPG has completed a PSR in accordance with Regulatory Document REGDOC-2.3.3 [R-9]. This IIP document represents the final deliverable in the PSR process.

Continued commercial operation of Pickering through 2024 will ensure that the province has a reliable source of Green-House-Gas (GHG)-free, baseload electricity. This represents an estimated reduction of GHG emissions of 17 million tonnes per year of extended operation. Continuing to operate Pickering NGS through 2024 not only contributes to the province meeting its environmental initiative, it is also associated with 4,500 direct and indirect jobs across the province.

1.1 Pickering NGS Performance

1.1.1 Safety Performance

Safety at all of OPG's facilities is an overriding priority and essential in the pursuit of achieving high performance goals.

Combining a safe robust design with mature programs that meet or exceed industry standards and regulatory requirements has allowed OPG to operate Pickering NGS safely for over 40 years. Continuous investments in plant condition, driven by strong reliability programs and an OPG leadership team that is committed to safety have enhanced performance throughout the plant's life.

Pickering NGS continues to have strong performance in all areas of safety with a conventional safety performance rating that is in the industry's top quartile.

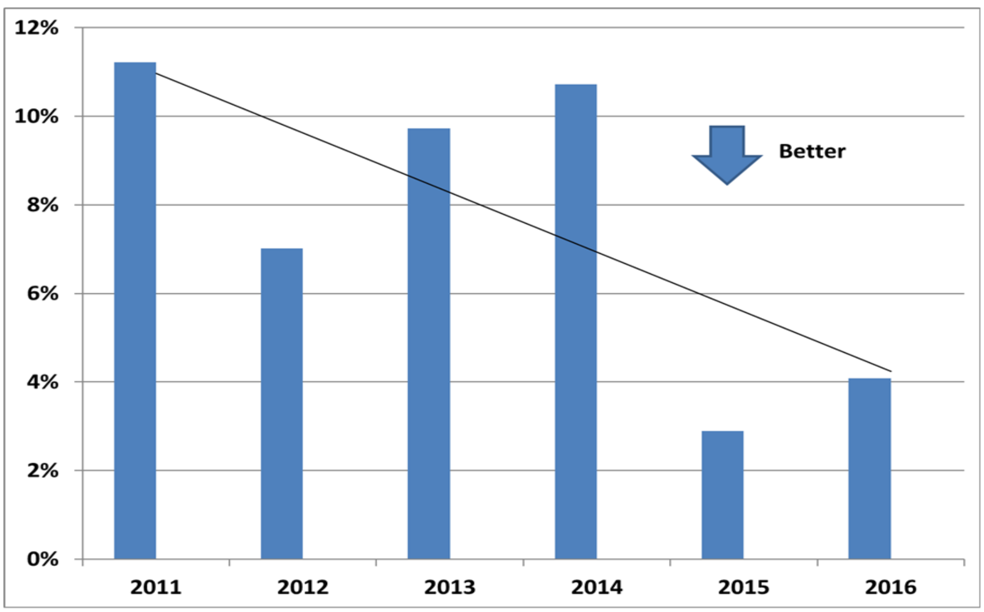
OPG has comprehensive Probabalistic Safety Assessments (PSA) in place for Pickering NGS 1,4 and Pickering NGS 5-8 that demonstrate the likelihood of a serious accident remains very low. OPG continues to invest to further enhance safety at its nuclear facilities as demonstrated by OPG's post Fukushima actions and the implementation of Emergency Mitigating Equipment (EME).

1.1.2 Reliability Performance

OPG has comprehensive programs in place that ensure the condition of Structures, Systems and Components important to safety at Pickering NGS is well understood, and that actions are effectively taken to continually improve plant condition. This is evident in the five year trend for Forced Loss Rate (Figure 1), an internationally recognized indicator of plant reliability and recognized by the CNSC[1] as an important indicator for program effectiveness.

For Pickering NGS, operational reliability has improved significantly over the years, with two of Pickering's units having record operational runs of 632 days for Unit 5 and 622 days for Unit 1. This, combined with the best Forced Loss Rate performance in site history at approximately 3% and 4% in 2015 and 2016, demonstrates the effectiveness of OPG programs and commitment to continuous improvement.

Figure 1: Pickering NGS Generation Forced Loss Rate (%)



1.1.3 Condition of Major Components

OPG has in place well established programs and processes that meet or exceed applicable regulatory requirements for ensuring that the physical condition of SSCs remain fit-for-service.

The current regulatory requirement is that major components, including fuel channels, be inspected during unit planned outages. The inspection results are compared against acceptance criteria defined in the appropriate CSA Standard and when required by the CSA standard, OPG submits fitness-for service assessments for CNSC acceptance to support return of the unit to service. In addition, inspection

[1] Section 12 of CNSC Regulatory Document 3.1.1, *"Reporting Requirements for Nuclear Power Plants*", a low station Forced Loss Rate reflects the effectiveness of stations programs and practices in maintaining systems available for safe electrical generation.

results are reported to CNSC following unit restart in accordance with the reporting criteria defined in the appropriate CSA Standard.

In keeping with OPG's "safety first principle", OPG will not operate a unit unless there is high confidence that all SSCs will remain fit-for-service for the operating cycle (next planned outage).

1.2 Pickering NGS PSR2

In support of licence renewal and continued commercial operation of Pickering NGS to the end of 2024, a Periodic Safety Review (PSR) has been completed in accordance with CNSC REGDOC-2.3.3 that was a comprehensive assessment of the Pickering NGS design and operation.

The objective of the PSR, referred to as PSR2 as it builds on the previous assessments was to confirm that the design, operation and safety-significant SSCs support continued safe operation of Pickering NGS to the end of 2024.

The PSR2 was conducted thoroughly by senior industry experts with different teams independently executing each of the four major phases:

1. **PSR2 Basis Document:** A PSR2 Basis Document defining the scope of the PSR2 process, and documenting the conduct of the PSR2 was prepared by OPG and accepted by the CNSC in July 2016.

2. **Safety Factor Reports:** Prepared by AMEC Foster-Wheeler and Tetra Tech, fifteen Safety Factor and two Complementary Reviews identifying compliances and gaps were submitted for CNSC review between July 2016 and March 2017.

3. **Global Assessment Report (GAR):** Prepared by Candesco, a division of Kinectrics Inc., that consolidated gaps based on the findings from the Safety Factor Reports and Complementary Reviews into Global Issues, prioritized Global Issues, developed Proposed Resolution Plans (which form the scope of the IIP), and ranked Proposed Resolution Plans. The GAR was completed and submitted for CNSC review in October 2017.

4. **Integrated Implementation Plan (IIP):** Prepared by RCM Technologies and OPG, documents specific actions that support the Global Issue Resolution Statements, referred to as Resolution Actions and IIP Actions (this document).

All of the above PSR2 phases were subjected to a third party Expert Panel review. The Expert Panel comprised senior industry leaders familiar with station design and operation of Pickering NGS and other nuclear stations, whose purpose was to provide guidance and counsel throughout the PSR2 process.

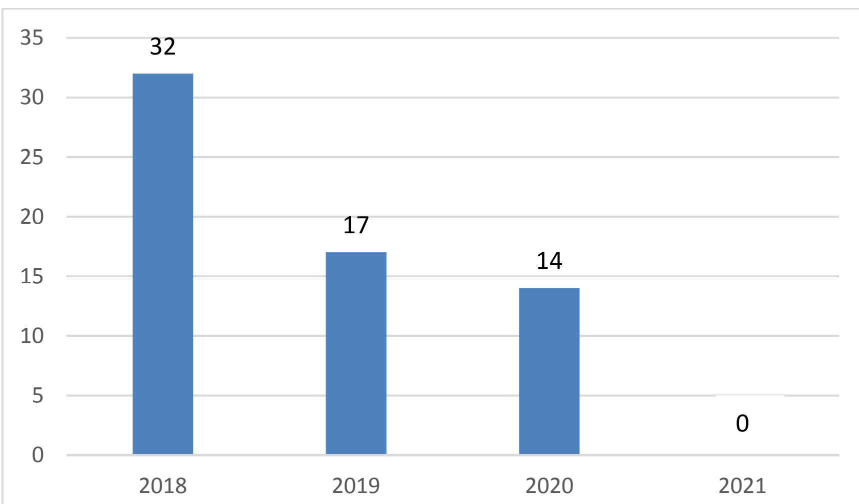
An overview of the four phases of the PSR2 process culminating in the development of the IIP Actions is summarized in section 2.0. Details of the activities carried out over the two year period on the PSR2 process are provided in Appendix D.

1.3 IIP Actions to Address Global Issues

Appendix B documents 63 IIP Actions that have been developed to address the proposed Resolution Statements for 23 Global Issues (GI) identified in phase 3 of PSR2. The 63 IIP Actions, based on current planning assumptions, have completion dates distributed over the next three years as shown in Figure 2, and baseline milestones as shown in Figure 8 in Appendix D.

Each IIP Action is scheduled for completion either through OPG's work management system for plant activities or through departmental work programs (e.g. OPG's *Integrated On-line Work Schedule*, N-PROC-MA-0022).

Figure 2: Distribution of IIP Actions and Timeline for Completing Actions



In addition to implementing programmatic improvements, this IIP contains actions for Plant Modifications, Fitness for Service, and Safety Analyses. The following key GIs are highlighted due to their significance to safety for continued operation to the end of 2024.

1.3.1 IIP Actions Involving Plant Modifications

1.3.1.1 Firewater System Enhancement (GI-48)

Canadian Standard Association (CSA) standard CSA N293-12, *Fire Protection for Nuclear Power Plants*, requires independent electrically and diesel driven firewater supply pumps. On Pickering NGS 1,4 this requirement is satisfied. However, a PSR2 gap was identified for Pickering NGS 5-8, as firewater is supplied from electrically driven pumps with redundant power supplies. To address this gap, changes to the existing Firewater system are included in the IIP scope to allow the Firewater from Pickering NGS 1,4 diesel driven Firewater pumps to supply Pickering NGS 5-8 through station interconnection. This interconnection will allow the Pickering site fire protection system to meet the safety intent of modern standards (CSA N293-12) for the redundancy and diversity of firewater supply.

1.3.1.2 Beyond Design Basis Accident (BDBA) Accident Management (GI-40)

OPG's response to the Fukushima accident included completion of:

1. Phase 1 Emergency Mitigation Equipment (EME) to prevent severe accident progression following a sustained station loss of power.

2. Phase 2 EME to restore critical containment functions.

These EME modifications greatly enhance safety at Pickering NGS; they were explicitly designed to mitigate the consequences of a sustained station loss of power event. The Phase 2 EME modifications included in Appendix B are intended to further enhance EME and BDBA coverage.

In addition to the EME modifications, OPG is updating the assessment (P-REP-09013-00002-R001, 2014-01-27, *Pickering NGS Beyond Design Basis Containment Integrity*) to cover operation to the end of 2024. This reassessment will include post-BDBA containment controlled filtered venting.

Lastly, OPG will upgrade the EME Phase 2 modifications to include the necessary power and support service connections to restore functionality of the Main Volume Vacuum Pump (MVVP).

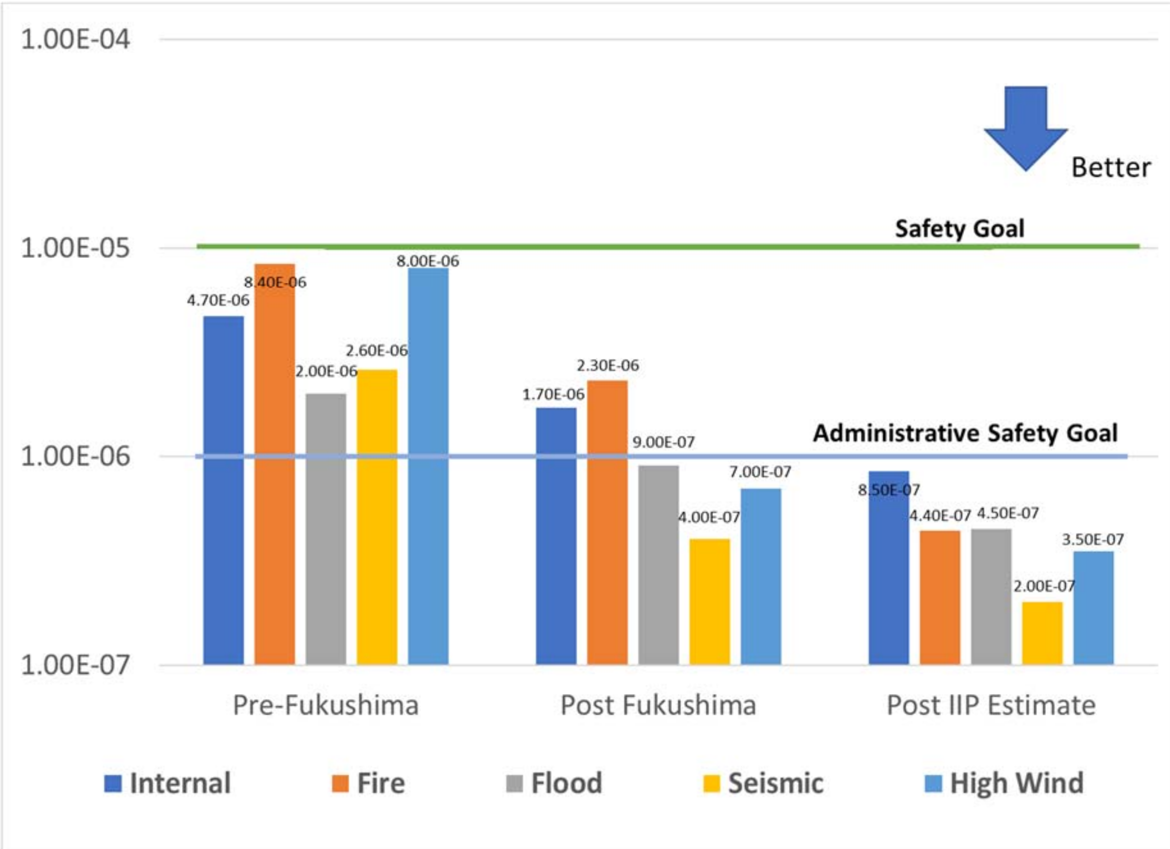
1.3.1.3 Pickering NGS 1,4 Probabilistic Safety Assessment (GI-27)

Even though Pickering PSA Safety Goals are met, OPG has set more challenging expectations through an Administrative Safety Goal. To meet the more challenging goals, OPG has implemented Fukushima lessons learned that have enhanced plant safety. Following Fukushima lessons learned action implementation, Pickering NGS 5-8 meets the Administrative Safety Goals in all areas.

Pickering NGS Units 1,4 PSA Large Release Frequency is already better than the Safety Goal. To ensure Pickering NGS 1,4 also meet the more challenging Administrative Safety Goal, IIP Actions have been established to install piping modifications to provide make-up water to Unit 1 and Unit 4 Calandria, Heat Transport System and Steam Generators to ensure continuous post-BDBA fuel cooling and protection of containment.

Following the completion of these enhancements as per the IIP Actions, Pickering NGS 1,4 PSA estimated LRF will be better than (i.e. lower than) the Administrative Safety Goal — further improving on already implemented Fukushima lessons learned actions, as shown in Figure 3.

Figure 3: Pickering NGS 1,4 PSA Large Release Frequency Improvements Following GI-27 IIP Action Completion



1.3.2 IIP Actions for Fitness for Service

Of the 23 Global Issues, there are three Global Issues of interest with regards to Fitness for Service, summarized below.

1.3.2.1 Completion/Updating of the Condition Assessments (GI-08 and GI-43)

The condition of the plant has been reviewed through Condition Assessments (CA), which ensures that appropriate maintenance, testing and monitoring are ongoing at

Pickering NGS. OPG continues to invest in the plant and to perform periodic component inspections to ensure that Pickering meets or exceeds industry standards.

Over a half million components covering all plant SSCs were reviewed through a defined process. Findings and recommendations were documented in over one thousand Condition Assessment (CA) reports. The CA recommendations cover operation beyond the expected commercial operation period to the end of 2024.

The goal of Global Issues GI-08 and GI-43 is to confirm the completeness of Pickering Condition Assessments to support commercial operation to the end of 2024.

The relevant IIP Actions that relate to Condition Assessments include:

1. Develop and implement into OPG governance a risk-based approach for aging management of critical passive components including piping systems, cables and civil structures.

2. Update Condition Assessment reports for various components including non-containment civil structures per the OPG's Aging Management Process (N-PROC-MP-0060).

3. Develop and implement a database for tracking and reporting on the implementation of CA actions in support of extended operation.

1.3.2.2 Fitness for Service for Fuel Channels (GI-01)

The goal of GI-01, "Fitness for Service for Fuel Channels", is to ensure that Fuel Channels remain fit-for-service for the extended operating period to the end of 2024.

As part of OPG's licence renewal application, OPG has requested approval to operate beyond the current Commission approved limit of 247,000 Effective Full Power Hours (EFPH) for the Pickering NGS 5-8 fuel channels, to 295,000 EFPH for the lead Pickering reactor unit.

This IIP contains the following actions that address Fuel Channel Fitness-for-Service:

1. Provide Revised OPG CSA N285.8 Compliance Plan.

2. Update Pickering NGS Fuel Channel Periodic Inspection Plan (PIP) for Operation to the end of 2024.

3. Submit 2018 Fuel Channel Life Cycle Management Plan (LCMP) Update that includes Pickering NGS 1,4 Operation to the end of 2024.

4. Prepare and update, as necessary, the "Pickering NGS Fuel Channel Readiness Plan in Support of Operation to 2024" that documents and provides the status of the work required in support of Pickering NGS operation to the end of 2024.

Annual submission of the Fuel Channel LCMP to the CNSC will continue per existing regulatory requirements.

1.3.3 Deterministic Safety Analysis to Support Extended Operation to the End of 2024 (GI-24)

OPG is committed to continuous improvement in safety at all of its nuclear facilities and has robust, comprehensive programs in place that are aligned with industry best practices for ensuring the condition of SSCs important to safety are well understood and well maintained. OPG maintains and routinely updates the Pickering NGS safety analysis to include aging effects, as required by CNSC REGDOC-2.6.3 [R-13]. The safety analysis demonstrates that the public risk from Pickering NGS remains very low.

The goal of GI-24, “Safety Analysis to Support the Extended Operating Period”, is to demonstrate the adequacy of the safety margins of the plant covering the extended operating period.

The most recent Heat Transport System (HTS) aging safety analysis (Small Break Loss of Coolant Accident (SBLOCA) and Loss of Flow (LOF)) are valid to January 31, 2019 for Pickering NGS 1,4 and June 20, 2019 for Pickering NGS 5-8. Neutron Overpower (NOP) safety analysis is also included in the scope of GI-24.

This IIP contains actions to perform and submit updated safety analysis per CNSC REGDOC-2.4.1, to support continued safe operation for extended operation.

1.4 Pickering PSR2 Conclusions

The PSR process has been thoroughly conducted over a two-year period by industry experts. The process has identified plant modifications that will enhance safety and reliability, and has highlighted where additional work is required to support commercial operation to the end of 2024. The PSR reviews confirmed that there are no management program gaps.

This IIP document has produced a baseline schedule of activities which are presented in Appendix B, and which will be controlled through regular OPG monitoring and reporting. Any changes to the baseline schedule (shown in Figure 8 in Appendix D) will be managed through the IIP Administration Instruction [R-14]. With a robust design, established mature programs in place that meet or exceed industry standards, and a leadership team that is committed to safety and continuous improvement, Pickering NGS will continue to operate safely and reliably through 2024.

2.0 PERIODIC SAFETY REVIEW (PSR2) SCOPE

The Pickering NGS PSR2 was conducted by senior industry experts, building on the review basis of earlier OPG PSR work (PSR1) and other associated assessments, consisting of:

- The Pickering B Integrated Safety Review (ISR), completed in 2009 and performed in support of the proposed refurbishment and continued operation (at that time planned for an additional 30 years) of Pickering NGS Units 5-8.
- Pickering NGS 1,4 integrated safety assessments performed during the Pickering A Return to Service (PARTS) work (circa 2000), in support of approval to restart Units 1 and 4.
- The relevant programmatic aspects of the Darlington ISR completed in October 2011 in support of refurbishment and continued operation of the Darlington units (programmatic parts are applicable to Pickering where programs and practices are common for the OPG fleet).

In accordance with CNSC REGDOC-2.3.3, Periodic Safety Reviews [R-9], the elements of PSR2 consisted of the following four phases submitted to the CNSC:

1. Preparation of a Basis Document [R-8].
2. Conduct of the Safety Factor (SF) reviews and identification of Compliances and Gaps.
3. Consideration in the Global Assessment process of the five levels of defence-in-depth, identified strengths of Pickering NGS design, operations and performance, analysis of Gaps, and identification of potential safety enhancements for Pickering NGS.
4. Preparation of an Integrated Implementation Plan (IIP) for the implementation of safety enhancements (this document).

An overview of the PSR2 process is shown in Figure 4. The PSR2 timeline is shown in Figure 9 in Appendix D. The activities carried out during the four phases over the two year period on the PSR2 process are detailed in Appendix D.

Figure 4: Overview of Pickering NGS PSR2

Pickering PSR2 Basis Document

- Prepared in accordance with CNSC REGDOC-2.3.3
- Documents how PSR2 was to be conducted
- CNSC Accepted

↓

Safety Factor & Complementary Reviews

- 15 Safety Factor and 74 Code & Standard reviews completed in accordance with CNSC REGDOC-2.3.3 resulted in 93 Gaps identified.
- 2 Complementary Reviews (COP & FAI Reassessments) completed which resulted in 26 Gaps identified.
- 23 Type III CNSC Additional Gaps and 1 Expert Panel Gap identified.

143 gaps identified for Global Assessment

↓

Global Assessment

- 143 gaps consolidated into 51 Global Issues (GIs)
- 117 proposed resolution plans developed for all 51 GIs
- 23 of the 51 GIs resulted in 35 proposed resolution plans with actions and followed the prioritization process
- 82 proposed resolution plans did not require progression to the IIP (22 NFAs, 35 ADs, 25 XRFs)
- 24 Strengths identified
- Defence-in-Depth reviews completed
- Ranking of Resolution Statements performed

23 GIs having 35 Resolution Plans required follow-up action in the IIP

↓

Integrated Implementation Plan

- 23 Global Issues carried into the IIP
- 35 Resolution Actions developed
- Completion and Success Criteria developed for Resolution Actions
- 63 IIP actions with completion criteria developed with Target Completion Dates
- IIP administrative and change control process developed

↓

IIP Actions Scheduled

- IIP activities scheduled for completion align with safety significance and unit planned outage schedule
- Tracking of IIP actions to completion and submission of closure requests for CNSC acceptance
- Quarterly and annual reporting on IIP progress

A summary of the Safety Factor reviews and Global Assessment are detailed below in Sections 2.1 and 2.2.

2.1 Safety Factor Review

Following the PSR2 Basis Document phase which defined the approach for how PSR2 was to be conducted, the second phase of the PSR2 process involved completion of 15 Safety Factor reviews, which covered all aspects important to the safety of Pickering NGS.

The results of the Safety Factor reviews were documented in 15 Safety Factor Reports. The Safety Factor Reports addressed the Review Tasks derived from IAEA SSG-25 [R-10] and from CNSC REGDOC-2.3.3 [R-9], and documented the results of the assessments of Pickering NGS with respect to applicable modern Laws, Regulations, Codes and Standards. Other complementary assessments, such as reassessment of the Pickering B ISR Continued Operations Plan (COP) actions and the Fukushima Action Items (FAIs) were also completed in the Safety Factor review phase.

The Safety Factor Reports and complementary assessments concluded that there are no fundamental safety issues at Pickering NGS, and that OPG has effective programs and processes in place to support continued safe operation for the extended operating period to the end of 2024.

The Safety Factor Reports identified compliances and gaps with respect to the review elements in the PSR2 assessment basis. Gaps identified in the Safety Factor Reports and complementary assessments, were then consolidated into Global Issues in the Pickering NGS Global Assessment during phase three of PSR2.

2.2 Global Assessment

The third phase of the PSR2 process, the Global Assessment, was the review of the findings of the Safety Factor reports, the Pickering B ISR COP and FAI complementary assessments, and Expert Panel reviews, to provide an overall assessment of the safety of the station, and confirm its safe operation for the extended operating period to the end of 2024. The Global Assessment included consideration of the identified design, operational and performance strengths, the five levels of defence-in-depth, the enhancements identified through proposed resolution plans, in order to make a conclusion on the overall acceptability of operation of the plant over the extended operating period to the end of 2024.

The Global Assessment concluded that the current plant design, operation, processes and management system will ensure continued safe operation of Pickering NGS Units 1, 4 and Pickering NGS Units 5-8 both in the short term, and for extended operation to the end of 2024.

The results of the Global Assessment are documented in the Pickering NGS Global Assessment Report [R-1].

The Global Assessment considered Safety Factor and complementary assessment gaps and compliances, identified Pickering NGS Strengths, and Defence-in-Depth Assessment conclusions. These factors were considered in aggregate to identify Global Issues and Resolution Plans, from which the IIP scope and schedule was derived.

2.2.1 Global Assessment Pickering NGS Strengths

As part of the Global Assessment, Strengths in Pickering NGS design, operations and performance were identified.

REGDOC-2.3.3 defines Strengths as current practices that are “equivalent to or better than those established in modern codes and standards, practices”. The Safety Factor Compliances (and groups of Compliances) were taken into the Global Assessment for consideration as Strengths.

The review to identify Strengths considered the following sources:

- Safety Factor Reports
- Codes and Standards Assessments
- Complementary Assessments (COP and FAIs)
- Independent Third Party Assessments (CNSC’s Regulatory Oversight Report for 2015 [R-12] and assessments/reviews by international organizations)

The methodology and the list of Strengths were reviewed by the Pickering NGS Global Assessment Expert Panel with extensive knowledge of the Pickering NGS PSR2 project and design/operation of Pickering NGS.

A total of 24 Strengths were identified for Pickering NGS, which are detailed in the Pickering NGS Global Assessment Report [R-1]. The Pickering NGS Strengths were used in the Defence-in-Depth Assessment to demonstrate the extent to which the safety requirements of defence in depth are fulfilled, as required by CNSC REGDOC-2.3.3.

Furthermore, OPG Pickering NGS Senior Leadership is committed to investing in the plant, and focusing the organization to strive for continued improvement in the plant condition, operation and performance.

2.2.2 Defence-in-Depth Assessment

As part of the Global Assessment, a Defence-in-Depth assessment was performed which supported extended operation at Pickering NGS by demonstrating the extent to which the safety requirements of defence-in-depth are fulfilled at Pickering NGS. The overall assessment was an important element in supporting the proposed enhancement plans and the planned operational strategy over the period of PSR2.

The following five levels of defence, listed below are defined in IAEA INSAG-10 [R-2], Defence in Depth in Nuclear Safety:

Level 1: Prevention of abnormal operation and failures

Level 2: Control of abnormal operation and detection of failures

Level 3: Control of accidents within the design basis

Level 4: Control of severe plant conditions, including prevention of accident progression and mitigation of the consequences of severe accidents

Level 5: Mitigation of radiological consequences of significant releases of radioactive materials

The Defence-in-Depth assessment considered the overall plant, as well as the identified strengths, acceptable deviations, and the proposed resolutions to the Global Issues listed in the Global Assessment.

The defence-in-depth concept applied to the Global Assessment was consistent with IAEA INSAG-10, Defence in Depth in Nuclear Safety [R-2]. The assessment used elements of the process described in IAEA SRS-46, Assessment of Defence in Depth for Nuclear Power Plants [R-3].

It was confirmed that the applicable safety principles from IAEA SRS-46 [R-3] for the concept of defence-in-depth was applied at the Pickering NGS design stage and throughout its operation over a period of several decades. At the design stage, the focus was on the first three levels of defence-in-depth: prevention of operation outside normal operating conditions, control of abnormal conditions, and provision of safety systems to effectively mitigate Design Basis Accidents (DBA). The capability of station systems and processes for responding to emergencies to mitigate the consequences of BDBAs, including severe accidents, was considered for defence-in-depth Levels 4 and 5.

The Defence-in-Depth assessment confirmed that at Pickering NGS, effective Level 1 barriers are ensured through the original conservative design, supplemented by design enhancements implemented since initial operation, comprehensive operating and maintenance programs in place, and ongoing continuous improvements based on national and international OPEX. Given the focus and priority placed on equipment reliability to address the findings in the areas of the equipment condition, this level of defence will continue to be strong and effective for Pickering NGS.

The assessment of defence-in-depth Level 2 confirmed that the provisions in place at Pickering NGS are mature and robust for detecting changes from normal operating conditions by the Reactor Regulating System, plant process control systems and the Special Safety Systems. The control systems in Pickering NGS maintain the reactor operating conditions within the normal operating range, and effectively respond to anticipated transients to avoid the need for safety system action.

The assessment of defence-in-depth Level 3 confirmed that effective provisions for the control of accidents within the design basis are provided at Pickering NGS. Operators have indications and alarms as well as the capability to perform actions from the Main Control Room for this purpose. The review confirmed that Pickering NGS has strong Level 3 barriers due to the high quality of the design, which is supported by a robust set of safety analyses, and the improvement initiatives to enhance equipment reliability.

The assessment of defence-in-depth Level 4 confirmed that Pickering NGS has additional design features and effective procedural provisions in place. Pickering NGS Units 1,4 and 5-8 have complementary design features for BDBAs. Operating Manuals and Abnormal Incident Manuals include Emergency Mitigating Equipment Guidelines to prevent accident progression. Severe Accident Management Guidelines for mitigating accident progression in the very unlikely event of a BDBA have been implemented. Furthermore, a mature emergency response infrastructure is in place, and the requisite qualified staffing and expertise are maintained.

The assessment of defence-in-depth Level 5 confirmed that the coordinated emergency response capability of the various response organizations and the implementation of OPEX from the Fukushima event supports the Level 5 defence-in-depth provisions. Implementation of the planned Fukushima improvement initiatives will further enhance the barriers for Level 5 at Pickering NGS.

The Defence-in-Depth assessment concluded that Pickering NGS Units 1,4 and 5-8 design and operation have effective barriers in all levels of defence-in-depth and that significant enhancements have been implemented since the plant was put into service.

2.2.3 Global Issues

OPG identified 120 gaps from various sources (e.g. Safety Factor Reports, Complementary Assessments and Expert Panel review) that were evaluated in the Global Assessment. The gaps were consolidated and grouped based on topical similarities, as Global Issues. This consolidation facilitated the analysis of any interfaces between Safety Factors and the aggregate impact of Global Issues. Each Global Issue was prioritized with respect to nuclear safety, and assigned a corresponding Safety Significance Level.

Subsequent to the conduct of the initial Global Assessment process, 23 Additional Gaps (AG) were identified from the CNSC staff review of the Safety Factor Reports and complementary reviews. In total through the PSR, 143 Gaps were incorporated into the Global Assessment resulting in 51 Global Issues.

None of the Global Issues identify a safety concern that requires additional planned or urgent action to be taken.

2.2.4 Development of Proposed Resolution Plans

Proposed resolution plans were developed to address the 51 Global Issues (GI) with consideration of safety benefit and practicability. The proposed Resolution Plans for each of the 51 Global Issues consisted of the following Resolution types:

- **Resolution Statements (RS):** An activity intended to address the Global Issue. There were 35 Resolution Statements covering 23 Global Issues (some GIs had more than one RS)

- **No Further Action (NFA):** An activity which had already been completed or had actions already underway outside of PSR2 to address the related Global Issue or where information had been found that addressed the Global Issue have been categorized as requiring No Further Action (NFA) within PSR2. 35 proposed resolution plans were categorized as NFA during the Global Assessment.

- **Acceptable Deviation (AD):** An activity for which it was determined that the proposed resolution had Low/Very Low Safety Significance or that practicable resolution(s) were not readily evident. There were 22 proposed resolution plans categorized as AD during the Global assessment.

- **Cross-Reference (XRF):** An activity that was covered by another resolution as Cross-Reference (XRF). 25 proposed resolution plans were categorized as XRF during the Global Assessment.

The Global Assessment process resulted in 23 Global Issues that have 35 Resolution Statements with defined actions, some of which reflect existing work programs and plans at the station that are already in progress.

All Global Issue Resolution Statements were ranked per the Global Assessment normalized ranking, from 1 to 35 in order of decreasing importance, as shown in Appendix A.

The 35 Resolution Actions, and the supporting 63 IIP Actions which define the scope of the IIP, are scheduled with ranking considered, and managed through a structured IIP Administration Instruction [R-14].

3.0 INTEGRATED IMPLEMENTATION PLAN

The fourth and final phase of the PSR2 process is the Integrated Implementation Plan (IIP) that defines Resolution Actions to address Global Issues. Each Resolution Action is completed through the execution of one or more IIP Actions.

Appendices A, B and C in this document define the Resolution Actions and their supporting IIP Actions. Such actions will be closed when CNSC is satisfied that their corresponding success criteria are met.

OPG has established a schedule to manage the completion of the Resolution Actions, and their supporting IIP Actions, with baseline target completion dates, as illustrated in Appendix D Figure 8.

Within OPG, accountability for the successful execution of the IIP has been assigned at the appropriate level, ensuring the commitment and engagement of the organization.

Furthermore, OPG has established IIP change control process and reporting arrangements – as part of OPG's Regulatory Management Governance framework – under a new instruction document, P-INS-03680-00001 [R-14].

3.1 Resolution Action and IIP Action Identification

The Resolution Actions and their associated IIP Actions are assigned unique identifiers which trace their origin and classification within the PSR2 process.

	Global Issue	Resolution Statement	Safety and Control Area	IIP Resolution Action	IIP Assignment
Resolution Action:	**G04**	**-RS2**	**-06**	**-08**	
IIP Action:	G04	-RS2	-06	-08	.1
	G04	-RS2	-06	-08	.2

For example: "G04-RS2-06-08" identifies the eighth Resolution Action ("-08") of the IIP associated with the second Global Assessment Resolution Statement ("-RS2-") related to the fourth Global Issue ("G04-") associated with CNSC Safety and Control Area six ("-06"). ".1" identifies the first IIP Action related to Resolution Action "G04-RS2-06-08". The IIP Actions are listed by SCA in Appendix C of this document.

The IIP Resolution Actions were transitioned into OPG's Asset Suite Action Tracking as Regulatory Commitment (REGC) Action Requests (ARs), and the IIP Actions were transitioned into Action Tracking as Regulatory Management (REGM) "assignments" associated with the corresponding REGC ARs. Within OPG's Action Tracking, the Resolution Actions are identified by specific AR numbers.

3.2 Completion and Success Criteria

Resolution Actions and their supporting IIP Actions have been developed by Senior Industry Experts and OPG Subject Matter Experts and were provided specific and measurable Completion Criteria.

The Completion Criteria establish the verifiable evidence that needs to be provided to consider a specific action as having fulfilled its intent as developed through the PSR2 process. The Completion Criteria may include measures such as completed and documented analysis, system inspections, or installed modifications.

The Resolution Actions were also provided specific and measurable Success Criteria. The Success Criteria establish the verifiable evidence that needs to be provided to consider the Resolution Action as having satisfied its purpose as developed through the PSR2 process. The Success Criteria may include measures such as submitted aggregate analysis results, system inspection results, or confirmation that installed modifications are Available for Service (AFS).

4.0 CONCLUSION

The Pickering Nuclear Generating Station (PNGS) has been operated safely by Ontario Power Generation (OPG) for over 40 years. Investments in plant condition, driven by strong reliability programs and Leadership have enhanced plant safety and reliability.

The opportunity to extend the plant life was recognised early in 2015. Over a two year period, the first three steps of a PSR were conducted as per CNSC REGDOC-2.3.3. The Global Assessment Report identified the work scope that supports continued safe and reliable commercial operation to the end of 2024.

The scope of the IIP comprises 63 IIP Actions that have been converted to a baseline schedule (Appendix B), with milestones shown in Appendix D Figure 8. In developing the IIP, the PSR2 process did not eliminate any potential nuclear safety enhancements based on cost alone.

The management infrastructure and processes are in place [R-14] to ensure that IIP schedule progress is monitored and reported, risks are identified early and mitigated as appropriate, and changes are controlled by approved procedure.

OPG is committed to continuous safety enhancement at its nuclear facilities and has robust comprehensive programs in place aligned with industry best practices. The PSR identified no safety issues for continued safe operation of Pickering NGS through 2024, and the actions within this IIP will further enhance safety.

5.0 DEFINITIONS AND ACRONYMS

ACU	Air Conditioning Unit
AD	Acceptable Deviation
AG	Additional Gap
AIFB	Auxiliary Irradiated Fuel Bay
ALARA	As Low As Reasonably Achievable
AR	Action Request
BDBA	Beyond Design Basis Accident
CANDU	Canada Deuterium Uranium
CA	Condition Assessment
CCA	Component Condition Assessment
CHR	Component Health Report
CNSC	Canadian Nuclear Safety Commission
CME	Common Mode Event
COP	Continued Operations Plan
CSA	Canadian Standards Association
CSI	CANDU Safety Issue
CT	Calandria Tube
DBA	Design Basis Accident
EBWS	Emergency Boiler Water System

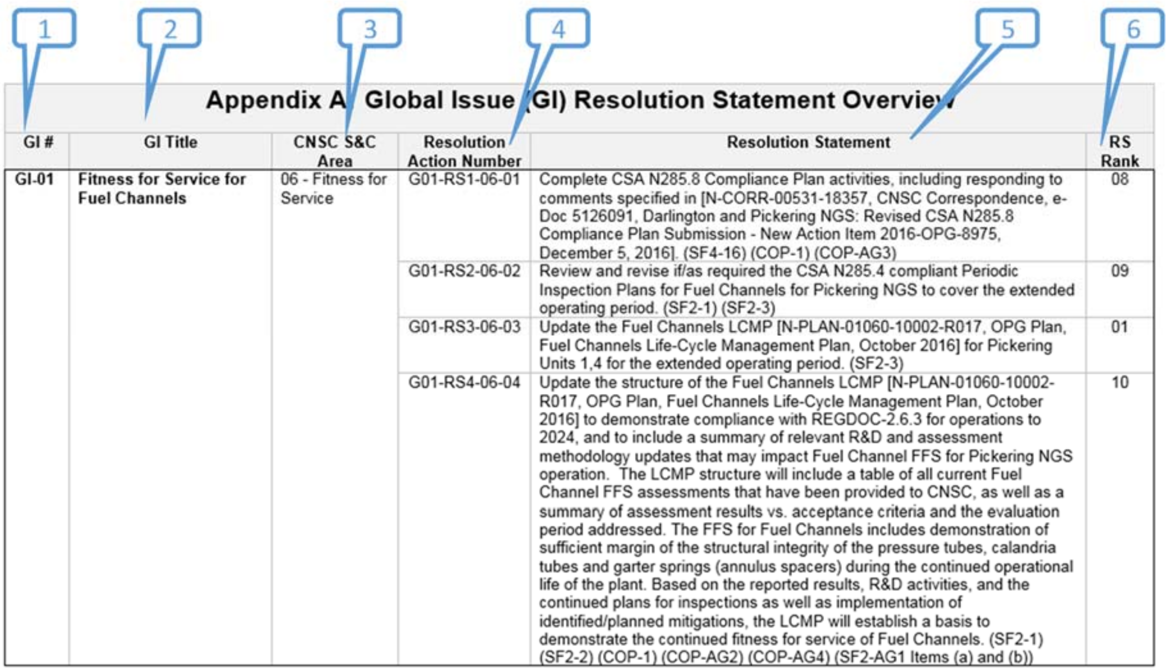
Appendix A: Global Issue (GI) Resolution Statement Overview

Resolution Statements for Global Issues identified in the Global Assessment Report are listed in Appendix A. Resolution Statements are proposed action statements to address a Global Issue, and are each given a unique Resolution Action numerical identifier for management through [R-14]. IIP Actions (Appendix B) have been produced as sub-actions of Resolution Actions, the completion of which, will complete the associated Resolution Action.



Appendix A Global Issue (GI) Resolution Statement Overview

GI #	GI Title	CNSC S&C Area	Resolution Action Number	Resolution Statement	RS Rank
GI-01	Fitness for Service for Fuel Channels	06 - Fitness for Service	G01-RS1-06-01	Complete CSA N285.8 Compliance Plan activities, including responding to comments specified in [N-CORR-00531-18357, CNSC Correspondence, e-Doc 5126091, Darlington and Pickering NGS: Revised CSA N285.8 Compliance Plan Submission - New Action Item 2016-OPG-8975, December 5, 2016]. (SF4-16) (COP-1) (COP-AG3)	08
			G01-RS2-06-02	Review and revise if/as required the CSA N285.4 compliant Periodic Inspection Plans for Fuel Channels for Pickering NGS to cover the extended operating period. (SF2-1) (SF2-3)	09
			G01-RS3-06-03	Update the Fuel Channels LCMP [N-PLAN-01060-10002-R017, OPG Plan, Fuel Channels Life-Cycle Management Plan, October 2016] for Pickering Units 1,4 for the extended operating period. (SF2-3)	01
			G01-RS4-06-04	Update the structure of the Fuel Channels LCMP [N-PLAN-01060-10002-R017, OPG Plan, Fuel Channels Life-Cycle Management Plan, October 2016] to demonstrate compliance with REGDOC-2.6.3 for operations to 2024, and to include a summary of relevant R&D and assessment methodology updates that may impact Fuel Channel FFS for Pickering NGS operation. The LCMP structure will include a table of all current Fuel Channel FFS assessments that have been provided to CNSC, as well as a summary of assessment results vs. acceptance criteria and the evaluation period addressed. The FFS for Fuel Channels includes demonstration of sufficient margin of the structural integrity of the pressure tubes, calandria tubes and garter springs (annulus spacers) during the continued operational life of the plant. Based on the reported results, R&D activities, and the continued plans for inspections as well as implementation of identified/planned mitigations, the LCMP will establish a basis to demonstrate the continued fitness for service of Fuel Channels. Content

(1) **GI #:** Global Issue (GI) number, as identified in the GAR.

(2) **GI Title:** Description of the GI.

(3) **CNSC S&C Area:** Resolution Action associated REGDOC-2.3.3 Safety and Control Area.

(4) **Resolution Action Number:** Unique numerical Resolution Action reference number used to manage Resolution Actions.

(5) **Resolution Statement:** The Resolution Statement for the associated GI as defined in the Global Assessment Report. The associated Safety Factor Report and Complementary Assessment gaps are listed in parentheses following each statement.

(6) **RS Rank:** Resolution Statement (RS) ranking as identified in the Global Assessment Report, ranked in order of the priority to address the GI, based on the magnitude and timeliness of the benefit to be achieved by its resolution.

GI #	GI Title	CNSC S&C Area	Resolution Action Number	Resolution Statement	RS Rank
GI-02	**Fitness for Service for Feeders**	06 - Fitness for Service	G02-RS1-06-05	Update the Feeders LCMP [N-PLAN-01060-10001-R018, OPG Plan, Feeders Life Cycle Management Plan, October 2016], based on updated Fitness for Service assessment for Pickering Units 1,4 for the extended operating period. The LCMP update is to support continued demonstration that predicted Feeder condition, with identified and planned mitigations, is acceptable for the intended operation, including any potential impact of Fuel Channel elongation on Feeder integrity. The Feeders LCMP update is to include a planned Feeder replacement plan/schedule to address the extended operating period. (SF2-4) (SF2-5) (COP-8)	02
GI-03	**Fitness for Service for Steam Generators**	06 - Fitness for Service	G03-RS1-06-06	Update the Steam Generators LCMP [N-PLAN-33110-10009-R007, OPG Plan, Steam Generators Life Cycle Management Plan, October 2016], based on updated Fitness for Service assessment for Pickering Units 1,4 for the extended operating period. The LCMP update is to support continued demonstration that predicted Steam Generator condition, with identified and planned mitigations, is acceptable for the intended operation. (SF2-6) (SF2-7) (COP-9)	03
GI-04	**Fitness for Service for Reactor Components and Structures**	06 - Fitness for Service	G04-RS1-06-07	Update the Reactor Components and Structures LCMP [N-PLAN-01060-10003-R014, OPG Plan, Reactor Components and Structures Life Cycle Management Plan, October 2016], based on updated Fitness for Service assessment and an updated Technical Basis Document [N-PLAN-01060-10008 R00, Reactor Components & Structures Life Cycle Management Plan: Technical Basis Document, 2010] for Pickering Units 1,4 for the extended operating period. The LCMP update is to support continued demonstration that predicted Reactor Components and Structures condition, with identified and planned mitigations, is acceptable for the intended operation. (SF2-8) (SF2-9) (COP-10) (COP-11) (COP-12) (COP-13) (COP-26)	04
			G04-RS2-06-08	Perform measurements, as required, of CT-LISS nozzle gaps on Units 5-8 to refine the gap closure rates. Using this new measurement data, update analyses as required, to demonstrate Fitness for Service. Implement mitigation strategies if CT-LISS nozzle contact is predicted within the extended operating period. (SF2-8) (COP-2) (COP-11) (SF2-AG1 Item (c)).	05

Appendix A: Global Issue (GI) Resolution Statement Overview

GI #	GI Title	CNSC S&C Area	Resolution Action Number	Resolution Statement	RS Rank
GI-05	**Completeness of Class 1 Piping / Components Service Limits Assessment (Excluding Major Components)**	06 - Fitness for Service	G05-RS1-06-09	Confirm the adequacy of the service limits assessments for Nuclear Class 1 Piping after accounting for impact of environmental factors (for example: irradiation, temperature, humidity). Note – This Resolution Statement does not address Major Components. (SF2-10)	11
GI-06	**Impact of the Revised Criticality Coding on the Cable Surveillance Program**	06 - Fitness for Service	G06-RS1-06-10	Reassess the impact of the changes in the cable Criticality Coding and update the scope of the cable surveillance plan accordingly. (SF2-13)	24
GI-07	**Pickering Buried Piping Fitness for the Extended Operating Period**	06 - Fitness for Service	G07-RS1-06-11	Update the Buried Piping Program asset management plan [N-PLAN-04916-10002 R003, Buried Piping Program Asset Management Plan, January 2017] and risk ranking [P-MAN-04916-00001-R002, Pickering Strategy Manual for Selection of Systems and Components for Inspection – Buried Piping, March 2014] for the extended operating period. (SF2-14)	25
			G07-RS2-06-12	Update governance to reflect a graded approach in the event that leakage in fuel oil piping occurs. This graded approach recognizes the nuclear safety importance of the systems being supplied with fuel oil, and would allow these systems to be temporarily repaired while awaiting further corrective action, allowing the systems to remain in service. This will involve document revision of Buried Piping Program Requirements [N-PROC-MA-0088-R003, Buried Piping Program Requirements, April 7, 2015]. (SF1-35)	35
GI-08	**Completion / Updating of the Condition Assessments**	06 - Fitness for Service	G08-RS1-06-13	Complete and update Condition Assessments (CA) for the piping systems and commodity groups in PSR2 scope for station operation for the extended operating period. Resulting recommendations will be assessed and included, as appropriate, in the CA action plans in the System and Component Health Reports. OPG is actively progressing with this work. (SF2-12) (SF2-15) (SF2-AG8 (b))	14
			G08-RS2-06-14	Develop and implement a process to track and report aging-management-related actions from the Condition Assessment recommendations. (SF2-12) (SF2-15) (SF2-AG4)	15

GI #	GI Title	CNSC S&C Area	Resolution Action Number	Resolution Statement	RS Rank
GI-09	**Seismic Capacity of the Conveyor Tube and Fuel Basket Stacking Arrangement**	05 – Plant Design	G09-RS1-05-15	Complete the required assessment to support the current fuel basket stacking arrangements in the Pickering IFBs. This seismic related issue was noted in the response to Fukushima Action Item FAI 2.1.2. Additional investigation is required to support the current spent fuel basket stacking arrangements in the Pickering IFBs. (SF2-17)	21
GI-10	**IFB Condition**	06 - Fitness for Service	G10-RS1-06-16	Complete the Pickering 5-8 IFB Leakage Mitigation Project [P-CORR-00531-04865, OPG Correspondence, Status Update: Pickering B Irradiated Fuel Bay Leak Mitigation Project #13-40703, Action Item 2014-48-5386, November 17, 2016] to mitigate leaks from IFB-B to the interspace. (SF2-16)	16
GI-12	**Extending the Environmental Qualification of Equipment**	05 – Physical Design	G12-RS1-05-17	Complete EQA re-assessments to support the extended operating period. (SF3-1)	17
GI-19	**FFS of Containment for the Extended Operating Period**	06 - Fitness for Service	G19-RS1-06-18	Demonstrate the FFS of the foundation steel H-piles for the Pickering A Reactor Building, Vacuum Building, and Pressure Relief Duct at the Pickering site for the extended operating period, as specified in [P-CORR-00531-04896, Pickering NGS: Continued Operations Plan (COP) Actions F06 and I15-6B - Periodic Safety Review Reassessment for Operation Beyond 2020, January 23, 2017] and in [P-CORR-00531-04973, Pickering NGS: CNSC Staff Review of OPG's Reassessment of COP Actions for Consideration in the PSR2, February 24, 2017]. (COP-25)	18
GI-24	**Safety Analysis to Support the Extended Operating Period**	04 - Safety Analysis	G24-RS1-04-19	Update Heat Transport System aging safety analysis models and perform the required safety analysis of the events most impacted by aging (SBLOCA, LOF and Neutron Overpower (NOP)) to support extended operation as per the existing practices [N-CORR-00531-18427, OPG Correspondence, Progress Report on OPG Heat Transport System Aging Safety Analysis, February 24, 2017]. (SF5-1) (COP-AG1)	06

Appendix A: Global Issue (GI) Resolution Statement Overview

GI #	GI Title	CNSC S&C Area	Resolution Action Number	Resolution Statement	RS Rank
GI-25	**Category 3 CANDU Safety Issues**	04 - Safety Analysis	G25-RS1-04-20	Complete the re-categorization of the Large Break LOCA (LBLOCA) CANDU Safety Issues to Category 2. OPG submitted an update to CNSC staff on the resolution of the LBLOCA issue [N-CORR-00531-18022, OPG Correspondence, Resolution of Large Break LOCA (LBLOCA) Safety Analysis Margin Issue, April 25, 2016]. An OPG update on the status of CSIs and their resolution is submitted to the CNSC annually, the latest being [N-CORR-00531-18052, Progress Update On Category 3 CANDU Safety Issues Implementation of Risk Control Measures, June 15, 2016]. Given the recent progress by industry in addressing the findings of CNSC staff reviews, it is expected that the remaining Category 3 CSIs will be re-categorized to Category 2 in 2017. OPG is actively progressing this work. (SF5-2) (COP-20)	34
			G25-RS2-04-21	Complete the re-categorization of CANDU Safety Issue CSI-IH6 for Pickering to Category 2. Complete the assessment of the layout of high-energy piping and Safety-Related Systems inside of the Reactor Buildings of Pickering Units 1 and 4 as per [P-REP-04960-00001 R002, OPG Report, Methodology of High-Energy Line Break Assessment for Piping Inside the Pickering Reactor Buildings, June 14, 2016]. For Pickering Units 5-8, the assessment is complete [N-CORR-00531-18052, OPG Correspondence, Progress Update on Category 3 CANDU Safety Issues – Implementation of Risk Control Measures, June 15, 2016] and a request for re-categorisation has been made [N-CORR-00531-18288, OPG Correspondence, Re-Categorization Request for CANDU Safety Issue IH6 for Pickering NGS 5-8 and Status for Pickering NGS 1-4, December 5, 2016]. For Pickering 1,4, a re-categorization request is planned for June 2018 [N-CORR-00531-18618, OPG Correspondence, Progress Update on Category 3 CANDU Safety Issues – Implementation of Risk Control Measures, June 23, 2017]. OPG is actively progressing this work. (SF5-2) (SF7-1) (SF1-9)	22
GI-26	**Emergency Response Projection Software**	10 - Emergency Management and Fire Protection	G26-RS1-10-22	Complete the emergency response projection enhancements identified in OPG Correspondence [N-CORR-00531-18136, Status Update for Action Item 2016-OPG-7469: Implementation of Emergency Response Projection Computer Code Upgrades, July 22, 2016], which are currently underway. (SF13-2)	20

Appendix A: Global Issue (GI) Resolution Statement Overview

GI #	GI Title	CNSC S&C Area	Resolution Action Number	Resolution Statement	RS Rank
GI-27	**Pickering 1,4 Probabilistic Safety Assessment**	04 - Safety Analysis	G27-RS1-04-23	Complete actions from PSA improvement Plan [P-CORR-00531-04946, OPG Correspondence, Pickering NGS: Risk Improvement Plan Update, February 28, 2017]. (SF6-1) (SF6-2)	23
			G27-RS2-04-24	Investigate and implement additional practicable design, operational and/or analytical enhancements to further improve Pickering 1,4 Severe Core Damage Frequency and Large Release Frequency (e.g., alternative emergency cooling water makeup). (SF6-1) (SF6-2) (FAI-AG1) (SF6-AG2) (SF6-AG3) (SF1-AG16)	07
GI-31	**Deterministic Safety Analysis**	04 - Safety Analysis	G31-RS1-04-25	Complete the Pickering NGS Implementation Plan for REGDOC-2.4.1 [N-PLAN-03500-0500515 R003, REGDOC-2.4.1 Implementation Plan, May 25, 2015]. The Implementation Plan at Pickering NGS was summarized in the PROL Amendment request as follows: “In alignment with current Pickering licensing requirements, and with the graded approach permitted by REGDOC-2.4.1 requirements, OPG will be upgrading the Pickering safety reports only to the extent that a new appendix will be included to address the development and analysis of common mode events in 2017. The analysis of common mode events represents the single largest gap in the Pickering Safety Reports with respect to REGDOC-2.4.1.” OPG is progressing this activity. (SF5-3)	30
			G31-RS2-04-26	Prepare Implementation Plan update for REGDOC-2.4.1 including consideration of the impact of the extended operating period. (SF5-4) (COP-21)	31
GI-32	**Implementation of REGDOC-2.4.2 PSA Requirements**	04 - Safety Analysis	G32-RS1-04-27	Complete the activities in the REGDOC-2.4.2 Implementation Strategy, as identified in Section 5.1, Safety Analysis Program, of [P-CORR-00531-04886, CNSC Correspondence, e-Doc 5121102, Pickering NGS: Licence Conditions Handbook, LCH-PNGS-R005, November 10, 2016] and update the Strategy in the context of the additional operating period. OPG is progressing this activity in support of extended operation at Pickering NGS. (SF6-4)	32

Appendix A: Global Issue (GI) Resolution Statement Overview

GI #	GI Title	CNSC S&C Area	Resolution Action Number	Resolution Statement	RS Rank
GI-40	**Accident Management**	10 - Emergency Management and Fire Protection	G40-RS1-10-28	Complete the planned Phase 2 EME implementation. This includes supplying cooling water, and power to essential loads via EME generators, to allow for operation of Air Cooling Units (ACUs) and Hydrogen Igniters [P-CORR-00531-04945, OPG Correspondence, Pickering NGS – CNSC Action Item 2016-48-7470 Status Update on Emergency Mitigating Equipment and Telecommunications Projects, February 16, 2017]. OPG is actively progressing this work in support of extended operation at Pickering NGS. (SF1-33) (SF1-AG4)	12
GI-43	**Safety-Related Structures (Non-Containment) for Nuclear Power Plants**	06 - Fitness for Service	G43-RS1-06-29	Perform the scope of inspections for non-Containment safety-significant civil structures as per the established Preventive Maintenance program (PM 00121151). (SF1-21) (SF1-22) (SF2-11) (SF4-13 Action #31)	19
			G43-RS2-06-30	Develop program governance using a risk based approach for aging management of safety-significant civil structures for the extended operating period. This applies to non-Containment Safety-Related Civil Structures (SF1-21) (SF1-22) (SF2-11) (SF4-13 Action #31)	28
			G43-RS3-06-31	Prepare Condition Assessments as appropriate for safety-significant civil structures for the extended operating period. Recommendations from these Condition Assessments will be tracked and reported along with those related to GI-8. This applies to non-Containment Safety-Related Civil Structures. (SF1-21) (SF1-22) (SF2-11) (SF4-13 Action #31)	26
GI-47	**Compliance With Fire Protection Code NFPA 24**	05 – Plant Design	G47-RS1-05-32	To resolve deviation #13301 from NK30-REP-71400-10001 R001 [NK30-REP-71400-10001 R001, OPG Report, Fire Protection Code Compliance Review Pickering Nuclear Generating Station B, November 23, 2010] the following work orders need to be completed to install wrenches and locks on the 058 Yard Fire Protection System: WO 3259862, 3259894, 3259893 (SF1-23)	27
GI-48	**CSA N293-12 Fire Protection of Nuclear Power Plants**	05 – Plant Design	G48-RS1-05-33	Provide, as necessary, design and/or operational changes and commissioning/testing to facilitate required interconnection of Pickering 1,4 and Pickering 5-8 Fire Protection System water supplies to meet the safety intent of CSA N293-12 Clause 7.3.2.2 (d). (SF1-5)	13

Appendix A: Global Issue (GI) Resolution Statement Overview

GI #	GI Title	CNSC S&C Area	Resolution Action Number	Resolution Statement	RS Rank
GI-50	**N285.4 PIP / Documentation Revision**	06 – Fitness for Service	G50-RS1-06-34	Revise the CSA N285.4 PIPs and governance to align with elements of N285.4-14, including making reference to CSA N285.4-14, addressing erosion and corrosion inspection requirements, reflecting extended life inspection schedules, and addressing assessment of the prior non-conforming state when dispositioning inspection results. (SF4-3) (SF4-5) (SF4-6) (SF4-7) (SF4-8)	33
			G50-RS2-06-35	Assess the impact of extended operation on concessions against CSA N285.4. (SF2-AG10)	29

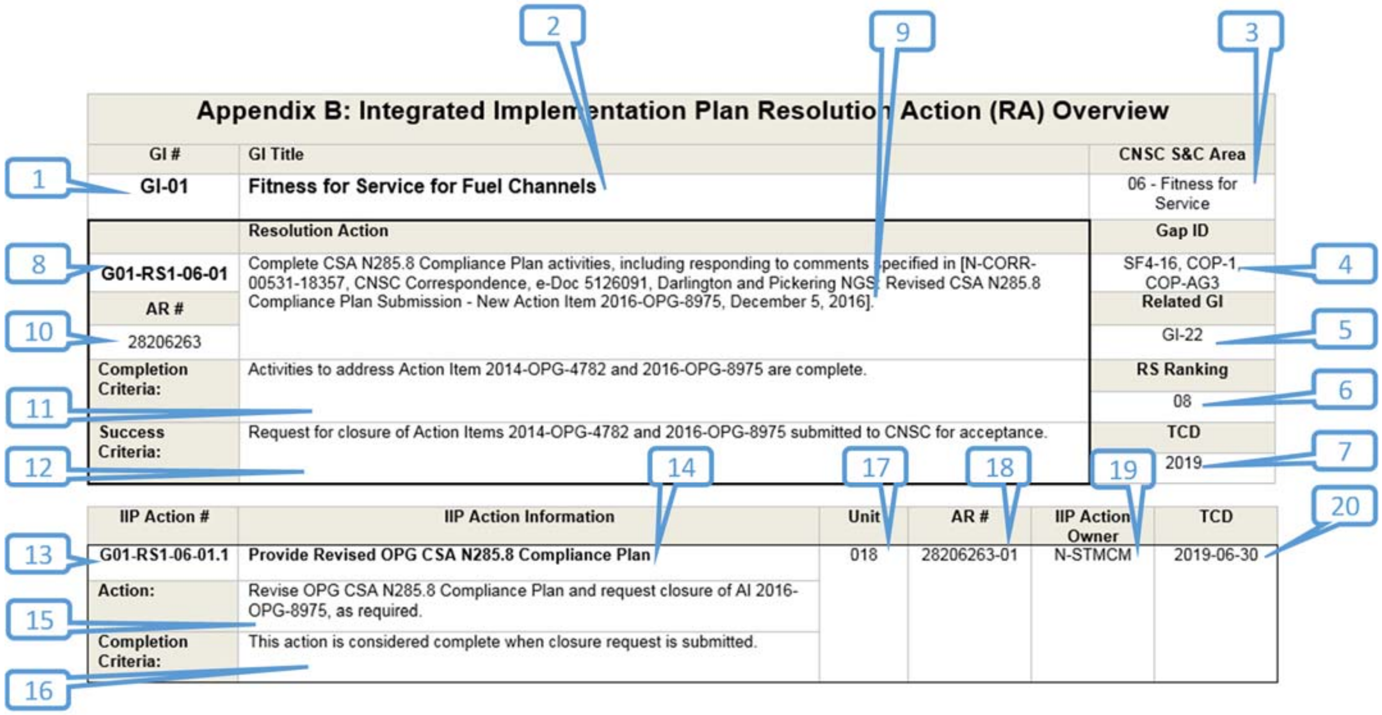
Appendix B: Integrated Implementation Plan Resolution Action Overview

Resolution Actions and their supporting IIP Actions are listed in Appendix B. The table is divided into three boxed areas: Global Issue information, Resolution Action, and IIP Action(s), each of which is described in detail below.

Global Issue information is listed at the top of the first table, to correlate the GI Resolution Statement to the associated gap(s), and to link any cross-referenced GIs. The information is used to facilitate understanding of the connection between the Safety Factor Reports, the Global Assessment Report, and the IIP.

The Resolution Action box is bolded to highlight the Resolution Action that will address the GI Resolution Statement. The information within the box identifies a unique numerical identifier and Action Request (AR) number used to manage the Resolution Action, and defines the Resolution Action, and the Resolution Action completion and success criteria. The Resolution Action is supported by IIP Actions.

The IIP Actions which support the Resolution Action are listed beneath the Resolution Action box. Each IIP Action is given a unique number, as well as an AR number to be tracked through [R-14]. The ranked IIP Actions and completion criteria are defined, as well as the associated Pickering NGS unit, IIP Action Owner, and IIP Action target completion date.



Content

Global Issue (GI) Information

(1) **GI #:** Global Issue (GI) number, as identified in the Global Assessment Report.

(2) **GI Title:** Description of the GI.

(3) **CNSC S&C Area:** Resolution Action associated REGDOC-2.3.3 Safety and Control Area.

(4) **Gap ID:** Safety Factor Report and Complementary Review gaps associated with the GI.

(5) **Related GI:** Cross-referenced (XRF) GIs which will be addressed by the Resolution Action.

(6) **RS Ranking:** Resolution Statement (RS) ranking as identified in the Global Assessment Report, ranked in order of the priority to address the RS, based on the magnitude and timeliness of the benefit to be achieved by its resolution.

(7) **TCD:** Resolution Action target completion date, by year.

Resolution Action Information

(8) **Resolution Action Number:** Unique numerical Resolution Action reference number used to manage Resolution Actions.

(9) **Resolution Action:** Global Issue Resolution Statement as defined in the Global Assessment Report.

(10) **AR #:** Action Request number generated in Asset Suite used to track the Resolution Action to completion through OPG's Action Item Management process.

(11) **Completion Criteria:** Specific criteria for the Resolution Action to be approved as complete by the IIP Manager.

(12) **Success Criteria:** Specific criteria for the Resolution Action to be accepted as closed by the CNSC.

IIP Action Information

(13) **IIP Action #:** Unique numerical IIP Action tracking reference, as a sub-action of the Resolution Action number, used to manage the IIP Action.

(14) **IIP Action Title:** Brief description of the IIP Action that will support completion of the Resolution Action.

(15) **IIP Action Description:** Detailed description of the IIP Action that will support completion of the Resolution Action.

(16) **IIP Action Completion Criteria:** Specific criteria for the IIP Action to be approved as complete by the IIP Action Owner.

(17) **Unit:** Pickering NGS unit(s) that the IIP Action is applicable to. 014 represents Pickering NGS Units 1,4, 058 represents Pickering NGS Units 5-8, and 018 represents common systems of Pickering NGS.

(18) **AR #:** Action Request number generated in Asset Suite used to track the IIP Action to completion through OPG's Action Item Management process.

(19) **IIP Action Owner:** IIP Action Owner responsible OPG department.

(20) **TCD:** IIP Action target completion date.

Appendix B: Integrated Implementation Plan Resolution Action (RA) Overview

GI #	GI Title	CNSC S&C Area
GI-01	**Fitness for Service for Fuel Channels**	06 - Fitness for Service
	Resolution Action	**Gap ID**
G01-RS1-06-01	Complete CSA N285.8 Compliance Plan activities, including responding to comments specified in [N-CORR-00531-18357, CNSC Correspondence, e-Doc 5126091, Darlington and Pickering NGS: Revised CSA N285.8 Compliance Plan Submission - New Action Item 2016-OPG-8975, December 5, 2016].	SF4-16, COP-1, COP-AG3
AR #		**Related GI**
28206263		GI-22
Completion Criteria:	Activities to address Action Item 2014-OPG-4782 and 2016-OPG-8975 are complete.	**RS Ranking** 08
Success Criteria:	Request for closure of Action Items 2014-OPG-4782 and 2016-OPG-8975 submitted to CNSC for acceptance.	**TCD** 2019

IIP Action #	IIP Action Information	Unit	AR #	IIP Action Owner	TCD
G01-RS1-06-01.1	**Provide Revised OPG CSA N285.8 Compliance Plan**	018	28206263-01	N-STMCM	2019-06-30
Action:	Revise OPG CSA N285.8 Compliance Plan and request closure of AI 2016-OPG-8975, as required.				
Completion Criteria:	This action is considered complete when closure request is submitted.				

IIP Action #	IIP Action Information	Unit	AR #	IIP Action Owner	TCD
G01-RS1-06-01.2	**Define Nominal Cooldown Transient for use in Probabilistic Leak-Before-Break (PLBB) Analyses**	018	28206263-02	N-STMCM	2018-06-30
Action:	Propose Nominal Cooldown Transient for use in Probabilistic Leak-Before-Break (PLBB)				
Completion Criteria:	OPG to submit closure request for the relevant condition associated with Action Item 2014-OPG-4782 to CNSC.				
G01-RS1-06-01.3	**Provide to CNSC documented evidence that validation of PLBB code is complete**	018	28206263-03	N-STMCM	2018-03-31
Action:	OPG to document evidence that validation of PLBB code is complete.				
Completion Criteria:	OPG to submit closure request for the relevant condition associated with Action Item 2014-OPG-4782 to CNSC.				
G01-RS1-06-01.4	**Address the Probabilistic Core Assessment (PCA) Flaw Removal Issue**	018	28206263-04	N-STMCM	2018-06-30
Action:	OPG to document resolution to address the Probabilistic Core Assessment Flaw Removal issue.				
Completion Criteria:	OPG to submit closure request of the Probabilistic Core Assessment Flaw Removal issue.				

Appendix B: Integrated Implementation Plan Resolution Action (RA) Overview

GI #	GI Title	CNSC S&C Area
GI-01	**Fitness for Service for Fuel Channels**	06 - Fitness for Service
	Resolution Action	**Gap ID**
G01-RS2-06-02	Review and revise if/as required the CSA N285.4 compliant Periodic Inspection Plans for Fuel Channels for Pickering NGS to cover the extended operating period.	SF2-1, SF2-3
AR #		**Related GI**
28206265		N/A
Completion Criteria:	Pickering Fuel Channel Periodic Inspection Plan updated to support operation to the end of 2024.	**RS Ranking** 09
Success Criteria:	The updated Fuel Channel PIPs for Pickering NGS to support operations to the end of 2024 submitted to CNSC for acceptance.	**TCD** 2018

IIP Action #	IIP Action Information	Unit	AR #	IIP Action Owner	TCD
G01-RS2-06-02.1	**Update Pickering NGS Fuel Channel Periodic Inspection Plan (PIP) for Operation to the end of 2024.**	018	28206265-01	N-STMCM	2018-12-31
Action:	Update the Fuel Channels Periodic Inspection Plans in support of Pickering NGS operation to the end of 2024.				
Completion Criteria:	This action is considered complete when the updated Periodic Inspection Plans has been submitted to CNSC.				

Appendix B: Integrated Implementation Plan Resolution Action (RA) Overview

GI #	GI Title	CNSC S&C Area
GI-01	**Fitness for Service for Fuel Channels**	06 - Fitness for Service
	Resolution Action	**Gap ID**
G01-RS3-06-03	Update the Fuel Channels LCMP [N-PLAN-01060-10002-R017, OPG Plan, Fuel Channels Life-Cycle Management Plan, October 2016] for Pickering Units 1,4 for the extended operating period.	SF2-3
AR #		**Related GI**
28206266		GI-22, GI-33
Completion Criteria:	Fuel Channel Life Cycle Management Plan (LCMP) updated for Pickering NGS Units 1,4 for operation to the end of 2024.	**RS Ranking** 01
Success Criteria:	2018 Fuel Channel LCMP submitted to CNSC.	**TCD** 2018

IIP Action #	IIP Action Information	Unit	AR #	IIP Action Owner	TCD
G01-RS3-06-03.1	**Submit 2018 Fuel Channel Life Cycle Management Plan (LCMP) Update that includes Pickering NGS U1 and U4 Operation to the end of 2024**	014	28206266-01	N-STMCM	2018-11-30
Action:	Update 2018 Fuel Channel LCMP to address operation of Pickering NGS Unit 1 and Unit 4 until the end of 2024.				
Completion Criteria:	This action is considered complete when the 2018 Fuel Channel LCMP N-PLAN-01060-10002 update has been submitted to CNSC.				

Appendix B: Integrated Implementation Plan Resolution Action (RA) Overview

GI #	GI Title	CNSC S&C Area
GI-01	**Fitness for Service for Fuel Channels**	06 - Fitness for Service
	Resolution Action	**Gap ID**
G01-RS4-06-04	Update the structure of the Fuel Channels LCMP [N-PLAN-01060-10002-R017, OPG Plan, Fuel Channels Life-Cycle Management Plan, October 2016] to demonstrate compliance with REGDOC-2.6.3 for operations to 2024, and to include a summary of relevant R&D and assessment methodology updates that may impact Fuel Channel FFS for Pickering NGS operation. The LCMP structure will include a table of all current Fuel Channel FFS assessments that have been provided to CNSC, as well as a summary of assessment results vs. acceptance criteria and the evaluation period addressed. The FFS for Fuel Channels includes demonstration of sufficient margin of the structural integrity of the pressure tubes, calandria tubes and garter springs (annulus spacers) during the continued operational life of the plant. Based on the reported results, R&D activities, and the continued plans for inspections as well as implementation of identified/planned mitigations, the LCMP will establish a basis to demonstrate the continued fitness for service of Fuel Channels.	SF2-1, SF2-2, SF2-AG1, COP-1, COP-AG2, COP-AG4
AR #		**Related GI**
28206267		N/A
Completion Criteria:	Fuel Channel Life Cycle Management Plan (LCMP) updated in support of Pickering NGS operations to the end of 2024.	**RS Ranking**
		10
Success Criteria:	Correspondence confirming that the fuel channel elements of the Major Components aging management program, which includes the fuel channel LCMP, complies with REGDOC-2.6.3 and includes all activities required to demonstrate Fuel Channel Fitness for Service in support of Pickering NGS operations to the end of 2024 is submitted to CNSC for acceptance.	**TCD**
		2020

IIP Action #	IIP Action Information	Unit	AR #	IIP Action Owner	TCD
G01-RS4-06-04.1	**Develop Pickering NGS Fuel Channel Readiness Plan in Support of Operation to the end of 2024 (FCRP2024)**	018	28206267-01	N-STMCM	2018-03-31
Action:	Prepare and update, as necessary, the “Pickering NGS Fuel Channel Readiness Plan in Support of Operation to 2024” (P-PLAN-31100-00002) that documents and provides the status of the work required in support of Pickering NGS operation to the end of 2024. The plan shall include, but not necessarily be limited to: • A roadmap that demonstrates compliance of Pickering’s Fuel Channel program with REGDOC-2.6.3. • Relevant R&D and assessment methodology updates. • A summary of required inspections. A summary of required assessments/evaluations and mitigation strategies.				
Completion Criteria:	This action is considered complete when the “Pickering NGS Fuel Channel Readiness Plan in Support of Operation to 2024” (P-PLAN-31100-00002) has been submitted to CNSC.				
G01-RS4-06-04.2	**Update and Submit 2018 Fuel Channel Life Cycle Management Plan (LCMP) and the Pickering NGS Fuel Channel Readiness Plan in Support of Operation to the end of 2024 (FCRP2024)**	018	28206267-02	N-STMCM	2018-11-30
Action:	Incorporate the results of the Pickering NGS FCRP2024 activities into Fuel Channel assessments/evaluations and identify actions to mitigate aging effects, as required. Update the FCRP2024 and the 2018 LCMP accordingly.				
Completion Criteria:	This action is considered complete when the FCRP2024 (P-PLAN-31100-00002) update and the 2018 Fuel Channel LCMP (N-PLAN-01060-10002) update have been submitted to CNSC.				

IIP Action #	IIP Action Information	Unit	AR #	IIP Action Owner	TCD
G01-RS4-06-04.3	**Update and Submit 2019 Fuel Channel Life Cycle Management Plan (LCMP) and the Pickering NGS Fuel Channel Readiness Plan in Support of Operation to the end of 2024 (FCRP2024)**	018	28206267-03	N-STMCM	2019-11-30
Action:	Incorporate the results of the Pickering NGS FCRP2024 activities into Fuel Channel assessments/evaluations and identify actions to mitigate aging effects, as required. Update the FCRP2024 and the 2019 LCMP accordingly.				
Completion Criteria:	This action is considered complete when the FCRP2024 (P-PLAN-31100-00002) update and the 2019 Fuel Channel LCMP (N-PLAN-01060-10002) update have been submitted to CNSC.				
G01-RS4-06-04.4	**Update and Submit 2020 Fuel Channel Life Cycle Management Plan (LCMP) and the Pickering NGS Fuel Channel Readiness Plan in Support of Operation to the end of 2024 (FCRP2024)**	018	28206267-04	N-STMCM	2020-11-30
Action:	Incorporate the results of the Pickering NGS FCRP2024 activities into Fuel Channel assessments/evaluations and identify actions to mitigate aging effects, as required. Update the FCRP2024 and the 2020 LCMP accordingly.				
Completion Criteria:	This action is considered complete when the FCRP2024 (P-PLAN-31100-00002) update and the 2020 Fuel Channel LCMP (N-PLAN-01060-10002) update have been submitted to CNSC.				
G01-RS4-06-04.5	**Submit Confirmatory Fuel Channels Fitness for Service Correspondence**	018	28206267-05	N-STMCM	2020-11-30
Action:	Prepare correspondence confirming that the 2020 Fuel Channel LCMP complies with REGDOC-2.6.3 and includes all activities required to demonstrate Fuel Channel Fitness for Service in of support Pickering NGS operations to the end of 2024.				
Completion Criteria:	This action is considered complete when the correspondence has been submitted to CNSC.				

Appendix B: Integrated Implementation Plan Resolution Action (RA) Overview

GI #	GI Title	CNSC S&C Area
GI-02	**Fitness for Service for Feeders**	06 – Fitness for Service
	Resolution Action	**Gap ID**
G02-RS1-06-05	Update the Feeders LCMP [N-PLAN-01060-10001-R018, OPG Plan, Feeders Life Cycle Management Plan, October 2016], based on updated Fitness for Service assessment for Pickering Units 1,4 for the extended operating period. The LCMP update is to support continued demonstration that predicted Feeder condition, with identified and planned mitigations, is acceptable for the intended operation, including any potential impact of Fuel Channel elongation on Feeder integrity. The Feeders LCMP update is to include a planned Feeder replacement plan/schedule to address the extended operating period.	SF2-4, SF2-5, COP-8
AR #		**Related GI**
28206269		GI-22, GI-33
Completion Criteria:	Feeders Life Cycle Management Plan (LCMP) N-PLAN-01060-10001 updated for Pickering NGS Units 1, 4 operations to the end of 2024.	**RS Ranking**
		02
Success Criteria:	Updated Feeders Life Cycle Management Plan (LCMP) N-PLAN-01060-10001 submitted to CNSC for review.	**TCD**
		2018

IIP Action #	IIP Action Information	Unit	AR #	IIP Action Owner	TCD

Appendix B: Integrated Implementation Plan Resolution Action (RA) Overview

GI #	GI Title	CNSC S&C Area
GI-50	**N285.4 PIP / Documentation Revision**	06 – Fitness for Service
	Resolution Action	**Gap ID**
G50-RS2-06-35	Assess the impact of extended operation on concessions against CSA N285.4.	SF2-AG10
AR #		**Related GI**
28206348		N/A
Completion Criteria:	Impact of N285.4 CNSC accepted program implementation concessions assessed for the extended operating period, and OPG implementation plans for identified elements for N285.4-14 updated as necessary.	**RS Ranking** 29
Success Criteria:	Update of implementation plans for identified elements of CSA N285.4-14 provided to CNSC for review.	**TCD** 2020

IIP Action #	IIP Action Information	Unit	AR #	IIP Action Owner	TCD
G50-RS2-06-35.1	**Assess the impact of extended operation on concessions against CSA N285.4**	018	28206348-01	N-CED	2020-12-31
Action:	Per P-CORR-00531-05099, assess the impact of N285.4 CNSC accepted program implementation concessions for the extended operating period, and update OPG implementation plans for identified elements for N285.4-14 as necessary.				
Completion Criteria:	Implementation plans updated for identified elements of CSA N285.4-14 as necessary.				

Appendix C: PSR2 Safety and Control Area (SCA) IIP Action Status List

IIP Actions defined in the IIP Resolution Action Overview (Appendix B), are listed by REGDOC-2.3.3 Safety and Control Areas in this Appendix C. The Appendix provides an overview of the IIP Action, associated Pickering NGS unit, and IIP Action target completion dates. The table provides a snapshot of the completion status of the IIP Actions at the time of submission of the IIP Report. IIP Action completion status following the IIP submission is managed through [R-14], with IIP Action status reported annually to the CNSC.

		G24-RS1-04-19.8	Complete Neutron Overpower safety analysis accounting for Heat Transport Aging (Pickering 5-8)	058	2019-03-31	
		G25-RS1-04-20.1	Re-categorization of the Large Break Loss of Coolant Accident (LBLOCA) CANDU Safety Issues (CSI) to Category 2	018	2020-06-30	

Content

(1) **SCA:** CNSC Safety and Control Area number, as defined in CNSC REGDOC-2.3.3.

(2) **SCA Description:** CNSC Safety and Control Area description.

(3) **IIP Action:** Unique numerical IIP Action tracking reference, as a sub-action of the Resolution Action number, used to manage the IIP Action.

(4) **IIP Action Title:** Brief description of the IIP action that will support completion of the Resolution Action.

(5) **Unit:** Pickering NGS unit(s) that the IIP Action is applicable to. 014 represents Pickering NGS Units 1,4, 058 represents Pickering NGS Units 5-8, and 018 represents common systems of Pickering NGS.

(6) **IIP Action Target Completion Date:** IIP Action target completion date.

(7) **IIP Action Completion Date:** IIP Action completion date, approved by the IIP Action Owner.

		G40-RS1-10-28.3	Upgrade Emergency Mitigating Equipment (EME) Phase 2 to restore the functionality of a Main Vacuum Volume Pump (MVVP)	018	2019-06-30	

Appendix D: PSR2 Process Overview

In support of extended operation of the six Pickering units to the end of 2024 and licence renewal, a Periodic Safety Review (PSR) was conducted in accordance with CNSC Regulatory Document 2.3.3, *Periodic Safety Reviews* and International Atomic Energy Agency's (IAEA) Safety Standards Series, Specific Safety Guide No. SSG-25, *Periodic Safety Review for Nuclear Power Plants.*

The following provides details on the PSR process used by OPG that lead to the actions specified in this Integrated Implementation Plan.

D 1.0 Introduction

CNSC REGDOC-2.3.3 and IAEA SSG-25 identify that subsequent PSRs should focus on changes in requirements, facility conditions, operating experience and new information, rather than repeating activities conducted in previous safety reviews. As such it is forward looking, focusing on: changes to requirements since the last applicable assessment, confirmation that the condition of Pickering NGS supports the additional years of commercial operation, and new operating experience since the last assessments.

The objective of Pickering's PSR was to confirm that the design, operation and safety-significant structures, systems, and components support continued safe operation and to determine reasonable and practical safety enhancements to further improve the already low risk of plant operation.

The subsequent PSR, referred to as PSR2, builds on earlier OPG PSR work (referred to as PSR1) and other associated assessments, specifically:

1. The Pickering B Integrated Safety Review (ISR), which included a comprehensive review of Codes and Standards that was completed in 2009 to support potential refurbishment and continued operation of Pickering NGS 5-8 for an additional 30 years.

   It was decided to not refurbish Pickering NGS 5-8, instead the option to extend operations to the end of 2020 without the replacement of the major reactor components. As a result, the Continued Operations Plan (COP) was developed and implemented for Pickering NGS 5-8 with an end of life of 2020.

2. Pickering NGS 1,4 integrated safety assessments were performed during the Pickering A Return to Service (PARTS) work in support of approval to restart Units 1 and 4 following the extended shutdown of these units. (The pressure tubes on these units had previously been replaced in the late 1980's and early 1990's). Based on the results of these safety assessments, termed Systematic Review of Safety, Pickering Units 1 and 4 were restarted. Pickering Units 2 and 3 were not restarted

and were placed in the safe storage state (fuel and water removed, systems isolated/de-energized, and separation from common containment).

3. The Darlington ISR was performed in support of refurbishment and continued operation of the Darlington units for an additional 30 years. Extensive reviews (primarily clause-by-clause reviews) of Codes and Standards were completed. Much of the compliance assessment and evaluation of Safety Factor health for the Darlington ISR was based on programs and practices that apply across OPG's nuclear operations. As a result, Darlington ISR programmatic conclusions are applicable to the Pickering PSR2 for nuclear programs and practices that are relevant to Pickering.

Pickering PSR1 results were determined to be applicable to PSR2 if there was an open PSR1 gap or if a closed PSR1 gap could be affected by extended operation. If so, these gaps were carried forward into the PSR2 for consideration in the Global Assessment.

D 2.0 PSR2 Scope

The safety of Pickering NGS is regularly and thoroughly assessed, verified and assured through several processes that are part of the current licensing framework. OPG also applies routine comprehensive safety assessment and improvement programs that deal with specific safety issues, significant events and changes in standards and operating practices as they arise. These programs allow assessment of safety and plant operation to be improved on a continuous basis that can be correlated to all of the Safety Factors reviewed in PSR2. They include programs that ensure safe operations, effective configuration management, equipment reliability, life cycle management, aging management, periodic inspection and maintenance. Programs are also in place in the area of organization management and safety culture that focus on safety-related behaviours and accountability.

D 2.1 Current Laws, Regulations, Codes and Standards Applicable to PSR2

The PSR evaluated the extent to which the plant meets current laws, regulations, codes and standards. The process to identify those documents applicable to the PSR2 assessment basis involved first creating a broad list from multiple sources (potential candidate laws, regulations, codes and standards) and then filtering them to identify those that were applicable to the PSR2 scope.

D 2.2 Structures, Systems and Components within the Scope of the PSR2 Review

The Structures, Systems and Components (SSC) within the scope of the PSR2 review encompassed the Systems Important to Safety (SIS) and the Safe Operating Envelope (SOE) systems and was restricted to the facilities that are regulated under the Pickering NGS Power Reactor Operating Licence. Therefore, the Pickering Waste Management Facility, which has a separate operating licence, was not considered within the Pickering PSR2 scope.

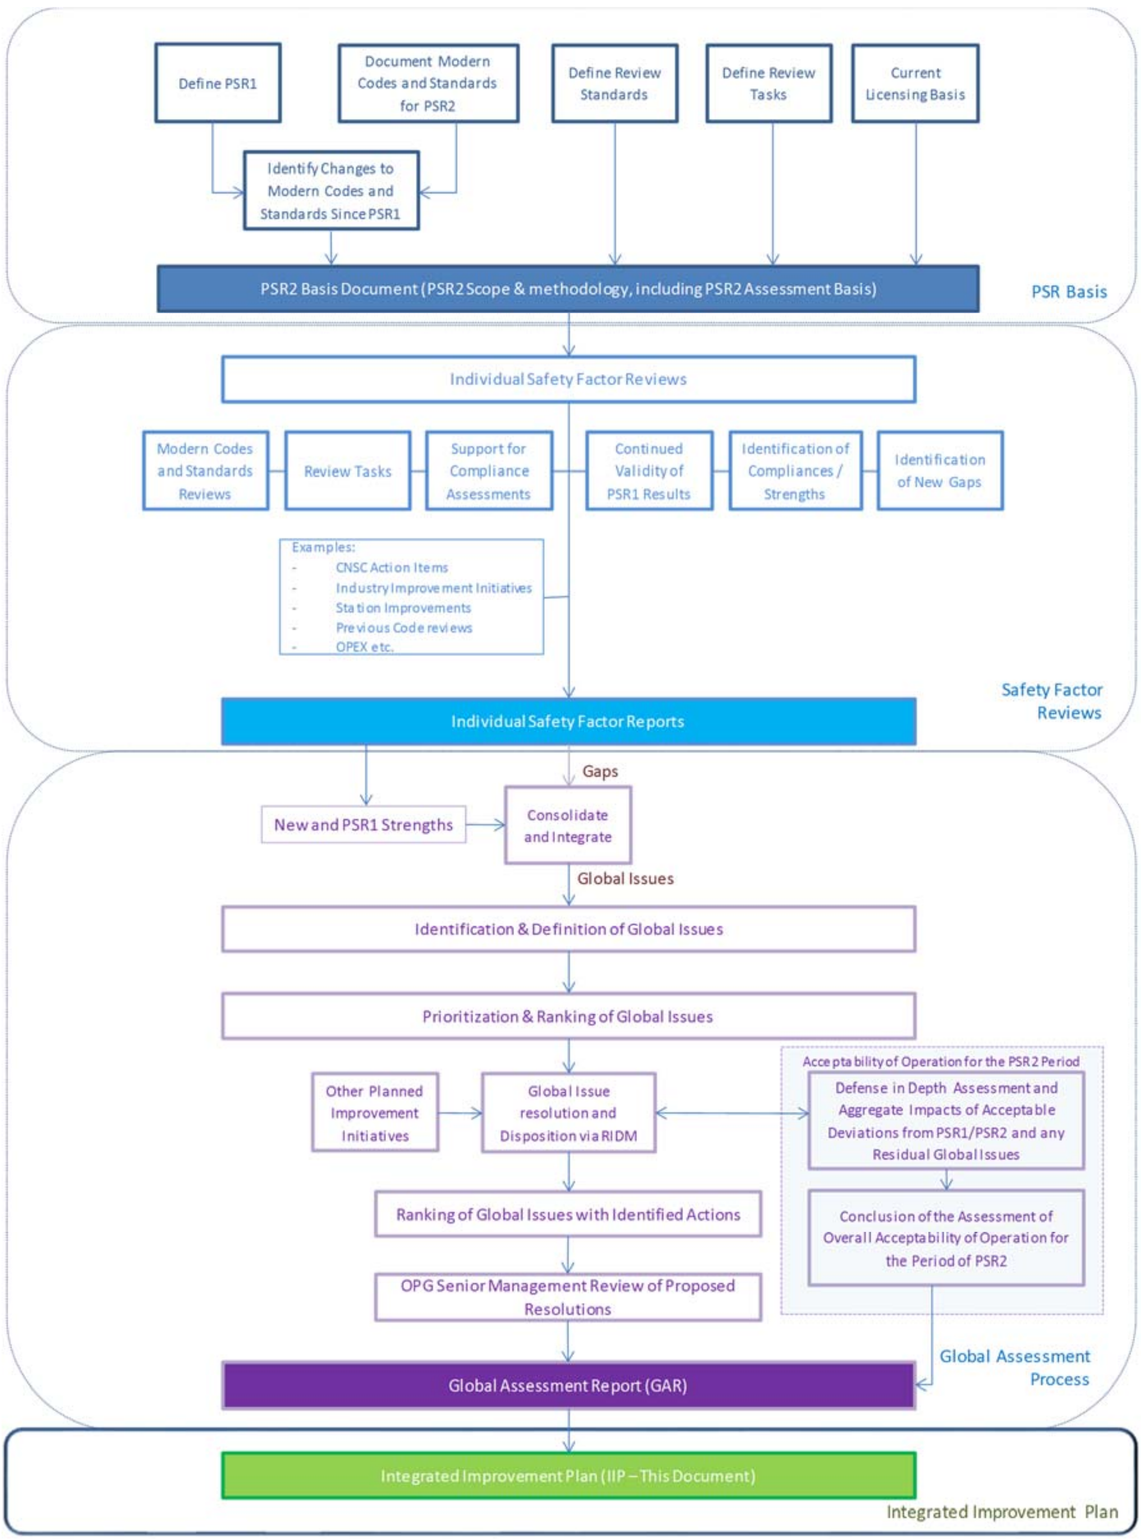
D 3.0 Details of the PSR2 Process

The general process overview for PSR2 is shown in Figure 6. Pickering's PSR2 was comprised of the following four key elements which are explained in the sections that follow:

1. PSR2 Basis Document
2. Safety Factor reviews
3. Global Assessment
4. Integrated Implementation Plan

Two additional assessments, referred to as "complementary assessments", (COP and Fukushima Action Items reassessments) were also performed to confirm the impact of extended operation beyond 2020. Where there were implications for extended operation, an associated gap was identified for consideration in the Global Assessment.

Figure 6: Pickering PSR2 Process Flowchart



D 3.1 PSR2 Basis Document

Pickering PSR2 Basis Document

- Prepared in accordance with CNSC REGDOC-2.3.3
- Documents how PSR2 was to be conducted
- CNSC Accepted

The Pickering PSR2 basis document, which was prepared by OPG and accepted by the CNSC in References D-2 and D-5 respectfully, defined the approach for completing the PSR2, specifically;

- The proposed operating strategy of the facility,
- Scope and methodology, including the conduct of Safety Factor reviews and identification of compliances and gaps,
- The process for categorizing, prioritizing, tracking and resolving Gaps arising from the Safety Factor reviews,
- Conduct of the Global Assessment,
- The methodology for preparing the Integrated Implementation Plan,
- Applicable current versions of Laws, Regulations, Codes and Standards,
- The major milestones, including the freeze date for document revisions, and,
- The project management and quality management processes.

D 3.2 Safety Factor Reviews

Safety Factor & Complementary Reviews

- 15 Safety Factor and 74 Code & standard reviews completed in accordance with CNSC REGDOC-2.3.3 resulted in 93 Gaps identified.
- 2 Complementary Reviews (COP & FAI Reassessments) completed which resulted in 26 Gaps identified.
- 23 Type III CNSC Additional Gaps and 1 Expert Panel Gap identified.

143 gaps identified for Global Assessment

Safety Factors cover all aspects important to the safety of an operating nuclear power plant, shown below in Table 1. There are 15 Safety Factors completed by Amec Foster-Wheeler used in the PSR2 review; 14 are identified in IAEA SSG-25, and one additional Safety Factor (Radiation Protection) as identified in CNSC REGDOC-2.3.3.

Table 1: PSR2 Safety Factors

Subject Area	Safety Factor	
The Plant	SF1	Plant Design
	SF2	Actual Condition of Structures, Systems and Components Important to Safety
	SF3	Equipment Qualification (environmental and seismic)
	SF4	Aging
Safety Analysis	SF5	Deterministic Safety Analysis
	SF6	Probabilistic Safety Assessment
	SF7	Hazard Analysis
Performance and Feedback from Operating Experience	SF8	Safety Performance
	SF9	Use of Experience from other NPPs and Research Findings
Management	SF10	Organization, the Management System and Safety Culture
	SF11	Procedures
	SF12	Human Factors
	SF13	Emergency Planning
Environment	SF14	Radiological Impact on the Environment
Radiation Protection	SF15	Radiation Protection

The results of the Safety Factor reviews were documented in Safety Factor Reports that have been submitted to CNSC. These reports include:

- The scope of the review,
- Applicable elements of the PSR2 Assessment Basis (Review Tasks and applicable Laws, Regulations, Codes and Standards),
- Review methodology,
- Assessment of compliance with Review Tasks,

- Effectiveness review of OPG programs supporting compliance assessments,
- Review findings (Compliances and Gaps),
- Impacts on other Safety Factor reviews,
- Overall assessment of the Safety Factor.

These reports concluded that there are no safety issues and that OPG has in place effective programs and processes for continued safe operation of Pickering NGS to the end of 2024. 143 gaps were identified from these Safety Factor reviews that were assessed in the Global Assessment.

As a subsequent PSR, the PSR2 Safety Factor reviews focused on changes in requirements (Laws, Regulations, Codes and Standards), updated plant conditions, operating experience and information from research, rather than repeating the activities of previous reviews. The methodology for performing the Safety Factor reviews takes full advantage of the safety assessments and Law, Regulation, Code and Standard compliance work previously completed by OPG.

This approach was in accordance with the guidance provided by the CNSC in REGDOC-2.3.3 that the effort required to undertake a subsequent PSR should require considerably less effort, subject to confirmation that previous conclusions remain valid.

D 3.3 Safety Factor Results and Reports

The Safety Factor reviews identified compliances and gaps with respect to the review elements in the PSR2 assessment basis. Specifically:

Compliance:

- For Clause-by-Clause reviews of current Laws, Regulations, Codes and Standards, Compliance indicates that the safety requirement is met.
- Where a High Level review has been performed, Compliance indicates that the intent of the safety requirement is met.
- Where an Incremental review has been performed, Compliance indicates that the change in the safety requirement, per the topical review, is met.
- For reviews of Safety Factor Review Tasks, Compliance indicates that either the safety requirement or the intent of the Review Task is met.

Gap:

- For Clause-by-Clause reviews of current Laws, Regulations, Codes and Standards, a gap indicates that the safety requirement is not met.
- Where a High Level review has been performed, a gap indicates that the intent of the standard is not met.
- Where an Incremental review has been performed, a gap indicates that the change in the standard, per the topical review, is not met.
- For reviews of Safety Factor Review Tasks, a gap indicates that the intent of the Review Task is not met.

Compliances that are equivalent to or surpassed PSR2 assessment basis requirements or practices were forwarded into the Global Assessment process for consideration as “strengths”. 24 strengths were identified and carried into the Global Assessment.

D 3.4 Global Assessment:

Global Assessment

- 143 gaps consolidated into 51 Global Issues (GIs)
- 117 proposed resolution plans developed for all 51 GIs
- 23 of the 51 GIs resulted in 35 proposed resolution plans following the prioritization process
- 82 proposed resolution plans did not require progression to the IIP (22 NFAs, 35 ADs, 25 XRFs)
- 24 Strengths identified
- Defence-in-Depth reviews completed
- Ranking of Resolution Statements performed

23 GIs having 35 Resolution Plans required follow-up action in the IIP

The objective of the Global Assessment was to provide an overall assessment of the safety of the plant, and to arrive at a judgement of the plant’s suitability for continued operation on the basis of a balanced view of the results from the reviews of the separate Safety Factors. This judgement takes into account the safety enhancements identified in the Global Assessment (plant and process modifications), strengths and residual Global Issues/acceptable deviations that impact on aggregate effects of the results, and consideration of existing planned safety enhancements and recent overall station safety performance.

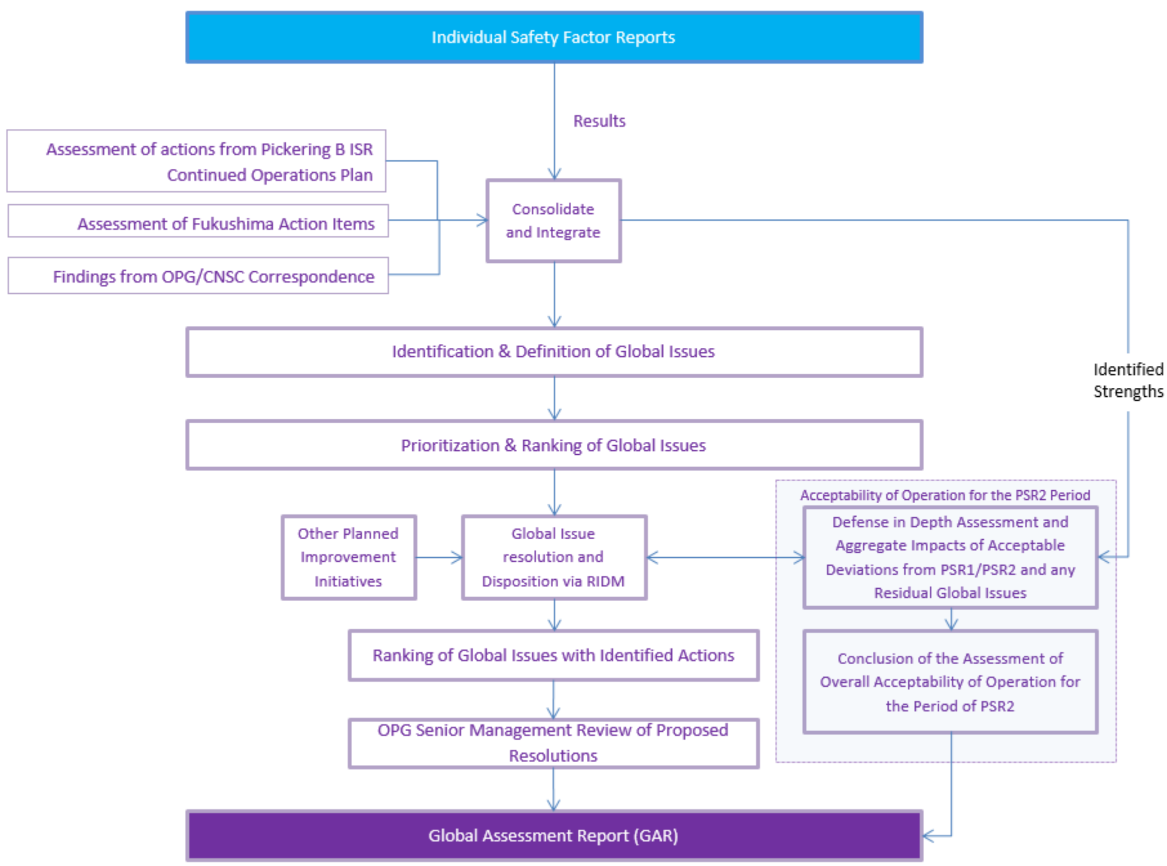
Consistent with the requirements of IAEA SSG-25, the Global Assessment was conducted by an interdisciplinary team (Candesco, a division of Kinectrics) with appropriate expertise in Operations, Design and plant safety, including appropriate participants from the safety factor reviews, and members who are independent from the Safety Factor review teams.

The Global Assessment Process consists of the following elements, shown below in Figure 8:

1. Identification and consolidation of Strengths and Gaps from the Safety Factor Reports.
2. Identification of Global Issues.
3. Assessment of interfaces between the various Safety Factors, Aggregate Impact of Global Issues.
4. Prioritization of Global Issues.

5. Development of Resolutions / Dispositions of Global Issues (and Gaps).
6. Consideration of defence-in-depth and aggregate impact of residual Global Issues / Acceptable Deviations.
7. Ranking of Global Issues with identified actions.
8. Senior Management Scope Review Board approval of proposed modifications for the purposes of PSR2.
9. Assessment of overall acceptability of operation of the plant over the period considered in PSR2.
10. Preparation of the Global Assessment Report to summarize the assessments, and document the Global Assessment.

Figure 7: Pickering NGS Global Assessment Process



D 3.5 Identification of Global Issues:

The gaps from the 15 individual Safety Factor Reports and two Complementary Reviews were consolidated and grouped by topic area into 51 Global Issues. The consolidation of gaps into Global Issues provided a means to assemble gaps of a common nature, facilitating the assessment of safety impact and identifying and assessing practical and effective resolutions.

D 3.6 Interfaces between the Various Safety Factors, Aggregate Impact of Global Issues:

With the assembly of Global Issues and strengths, and considering the recommendations from component condition assessments, the aggregate impact of the Global Issues was assessed to identify the interaction between issues.

D 3.7 Prioritization of Global Issues

Consistent with OPG prioritization processes used in previous Integrated Safety Reviews and industry practice, the Global Issues were prioritized with respect to their importance to nuclear safety.

The Safety Significance Level considered deterministic and probabilistic safety analysis impact, as appropriate. The assignment of safety significance values for prioritization was derived based on OPG experience and takes into account the priority values from the OPG guidelines for evaluating and prioritizing Safety Report Issues, the COG benefit-cost analysis processes, and the OPG station condition record categorization process. Probability levels selected for delineation between categories were based on significance and engineering judgement, and account for overall safety impact and align, where appropriate, with requirements and limits in relevant safety standards. The relationship between Safety Significance Level and impact on nuclear safety is shown in the Table 2.

Table 2: Relationship between Safety Significance Level

and Impact on Nuclear Safety

Safety Significance Level	Impact on Nuclear Safety
1	High
2	Medium
3	Low
4	Very Low

D 3.8 Development of Resolutions/Dispositions of Global Issues (and Gaps)

Resolution options were developed and assessed using risk-informed decision making techniques utilizing the following strategy:

- In assessing potential dispositions, defence-in-depth elements were considered.
- In developing the resolutions, consideration of overall safety significance will guide the resolution process.
- For Global Issue resolution – the process involved:

  - Evaluate the Global Issue to understand the safety basis, and intent of the requirement.
  - Consider possible options for resolution/mitigation. Consider safety significance and defence-in-depth elements.
  - Evaluate options with respect to effectiveness, cost, schedule, practicality. For potential plant modifications, this may require an evaluation of the safety impact, via both deterministic and probabilistic methods. If it is not practicable to fully resolve a Global Issue, other mitigation options were considered for enhancements.
  - Practicality of a proposed resolution was evaluated in terms of cost, resources, schedule, and considered in relation to the overall safety impact.
  - Propose recommended resolution/mitigation.
  - Document the decision making process.

- Items of High or Medium impact on nuclear safety (Safety Significance Levels 1 and 2) required more in-depth analysis to fully understand the issue and potential impact, and to develop the proposed resolution/mitigation. This required deterministic and/or probabilistic assessments to determine the nuclear safety impact of modifications and more detailed evaluation of the cost/practicality of proposed resolutions. Insights from available probabilistic safety analyses were used in evaluating the benefit/practicality of potential options.

- Items of Very Low Impact on Nuclear Safety (Safety Significance Level 4) were generally be deemed as Acceptable Deviations within the context of PSR2 (with the rationale provided). While these items were not tracked beyond the Global Assessment, they were shared with the accountable organizations for consideration as potential enhancement initiatives for their future work program planning purposes. A similar treatment was applied for items of Low Impact on Nuclear Safety (Safety Significance Level 3) for which a practicable solution was not readily evident.

- Proposed resolutions were categorized as follows:
  i) Programmatic (changes to procedures and programs),
  ii) Engineering (plant modifications), or
  iii) Analytical (e.g., safety analysis)

- In some cases, the development of resolutions/dispositions to the Global Issues were part of an OPG or industry initiative underway or planned. Or, the resolution and development of options required more detailed analysis and assessment, extending beyond the timelines for submission of PSR2. In these instances, the status of the initiative and plans were included in the disposition. The work was included in the Global Assessment to facilitate continued tracking.

- If the assessment determined that a Global Issue/gap had been closed, either by work done in the interim or by other processes, the rationale was documented and the Global Issue/gap was set to No Further Action (NFA) within the PSR process.

D 3.9 Consideration of Defence-in-Depth and Aggregate Impact of Residual Global Issues / Acceptable Deviations

An important element of the development of proposed recommendations were to assess the overall defence-in-depth and aggregate impact of the residual Global Issues/acceptable deviations. After evaluating a range of resolutions for Global Issues, and determining a recommended resolution to be selected, the impact on defence-in-depth, considering both deterministic and probabilistic elements, were evaluated to assess the aggregate impact on overall safety. This overall assessment was an important element in supporting the enhancement plans and the planned operational strategy over the period of PSR2.

D 3.10 Ranking of Global Issues with Identified Actions

All Global Issues whose resolution involves identified actions were ranked in accordance with overall safety significance, with consideration of factors such as impact to Nuclear Safety and timeliness to realize the benefit. This was based on engineering judgement applied by the Global Assessment team. The ranking process considered factors such as the priority previously determined (Safety Significance Level), the contribution to defence-in-depth, and the significance of the source (e.g., the type of document that generated the gap leading to the global issue). The ranking process also accounted for the extent of impact on multiple safety factors or areas.

D 3.11 Senior Management Scope Review Board Approval of Proposed Modifications for the Purposes of PSR2

The enhancements identified in the PSR2 Global Assessment Report, with their priority and safety basis, were presented to the OPG Senior Management Scope Review Board for approval. This review ensured alignment with the resolutions proposed, their basis and context, and was the means to obtain concurrence that the proposed enhancements are practicable and would be effective. Consistent with OPG project management processes, additional approval gates were required as the resolution development continues towards full implementation.

D 3.12 Assessment of Overall Acceptability of Operation of the Plant over the Period Considered in PSR2

As a final step in the assessment process, the team confirmed the overall acceptability of operation of the plant over the period considered in the PSR2. This entailed a review of the results of the safety factor reviews, a consideration of enhancements planned (both newly identified in PSR2 and from other station initiatives) and a consideration of plant performance.

D 3.13 Global Assessment Report

Preparation of the Global Assessment Report was conducted to summarize the Safety Factor Reports and Complementary Re-assessments and to document the Global Assessment by presenting the results, assessing the overall defence-in-depth of the plant, and documenting the conclusions, corrective actions, and enhancements to be considered. Appendix C of the Global Assessment Report includes a ranked list of those Global Issues with proposed resolution statements, with rationale for the ranking.

The Global Assessment Report also includes a statement of OPG's assessment of the overall acceptability of operation of the plant. Reviews and approval of the report were conducted as required under the OPG Management System.

As documented in Reference D-7, the GAR (P-REP-03680-00032-R001) was submitted to the CNSC in February 2018.

D 3.14 Integrated Implementation Plan:

Integrated Implementation Plan

- 23 Global Issues carried into the IIP
- 35 Resolution Actions developed
- Completion and Success Criteria developed for Resolution Actions
- 63 IIP actions with completion criteria developed with Target Completion Dates
- IIP administrative and change control process developed

The proposed enhancements resulting from the Global Assessment are documented in the Integrated Implementation Plan (IIP). Prepared by RCM Technologies, the IIP documents the enhancements (IIP actions) for addressing the Global Assessment Resolution Statements with target completion dates.

The IIP actions represent incremental enhancements that are in addition to OPG's continual improvement activities currently underway.

The enhancements summarized in the IIP were mapped to the CNSC Safety and Control Areas (per Appendix B of CNSC REGDOC-2.3.3), which are listed by SCA in Appendix C of the IIP.

D 3.15 Integrated Implementation Plan Logistics

The IIP listing of enhancements will include those resulting from the Global Assessment Report, including both new modifications proposed as part of the resolution of Global Issues, and also considering the existing planned station modifications that were integral to the overall assessment of safety.

A review was conducted with program owners and appropriate managers to derive plans for implementation based on priority and resources. These plans were developed with consideration of the other important initiatives underway or planned at Pickering NGS as part of continual improvement.

The initiatives were tabularized in Appendix B of this IIP, with owners assigned and planned implementation dates. Existing initiatives integral to the overall assessment of safety during the Global Assessment will also be included in this listing. The listing will include the priority and the basis for the priority. The implementation of the initiatives will be tracked and reported.

D 3.16 Integrated Implementation Plan Format

The IIP has been structured to allow a reader to understand the implementation plan and the basis for the plan. Appendices A, B and C within the IIP documents the IIP Actions along with their target completion dates. The IIP Actions include new initiatives that came from the Safety Factor Reports and the Global Assessment Report, and the existing initiatives that were integral to the overall assessment of safety.

The IIP was presented in a manner aligned with the CNSC Safety and Control Areas. The report summarizes the implementation tracking and reporting process and the IIP change management process. These processes will allow tracking of initiatives to completion or resolution in an auditable manner, consistent with OPG's management system.

D 3.17 Complementary Review: Continued Operations Plan (COP) Reassessment

In accordance with the PSR Basis Document [D-2], the Pickering NGS 5-8 Continued Operations Plan (COP) actions were reviewed to determine if there were implications for PSR2. Specifically, the COP actions pertaining to the Pickering NGS 5-8 Integrated Safety Review from 2009 and the Fitness for Service actions were reassessed for implications given the intent to operate Pickering NGS 5-8 beyond 2020.

In addition, implications for Pickering NGS 1,4 were also identified. Where there are implications for extended operation of Pickering NGS 5-8, or for Pickering NGS 1,4, a PSR2 gap was identified that was considered in the Global Assessment process described above.

D 3.18 Complementary Review: Fukushima Action Plan Reassessment

Following the events at Fukushima Daiichi in March 2011, the CNSC issued Fukushima Action Items to the Canadian Nuclear Utilities to ensure that the lessons learned from the event were appropriately incorporated into Canadian nuclear operations.

OPG has been recognized for its achievements in operational and management excellence in its response to the Fukushima Daiichi event and has confirmed that its stations remain safe with systems and procedures in place to deal with beyond design basis events.

OPG has taken the key lessons learned from the Fukushima event and incorporated changes to further enhance the safety of OPG's nuclear facilities. In 2015, all Phase 1 Fukushima Action Items (FAIs) for the Darlington and Pickering Units were closed.

In accordance with the PSR2 Basis Document, all of the FAIs pertaining to Pickering NGS were reassessed to determine if the basis for their closure remained valid in the context of intended extension of commercial operations of the station beyond 2020. This FAI reassessment, which was submitted to the CNSC in March 2017 did not identify any gaps for PSR2, however, two items were carried over to the Global Assessment as additional gaps as identified by the CNSC.

D 3.19 Findings from CNSC Staff Reviews of Safety Factor Reports and Complementary Reviews

From the CNSC staff review of the 15 Safety Factor Reports and Complementary Reviews, 77 Additional Gaps (AGs) were identified which were grouped into the following categories:

a) Type I & II: Provision of information. There were 54 AGs related to CNSC requests for additional supporting information to demonstrate program effectiveness or additional evidence for statements made by OPG in the Safety Factor and Complementary Review Reports.

b) Type III: Specific technical issues. There were 23 AGs related to CNSC identification of technical concerns, or demonstration of adequacy of implementation/response to issues of concern to CNSC.

The majority (54 of 77) of the AGs were Type I & II (requests for additional information) that will be addressed by OPG before March 15, 2018 [D-6]. None of these AGs invalidate the conclusions of the associated report.

The remaining 23 AG's Type III AGs were assessed in the Global Assessment and consolidated with other related PSR2 Gaps for the development of appropriate resolution statements.

D 4.0 PSR2 Results

The 15 Safety Factor review reports conclude that there are no fundamental safety issues and that OPG has in place effective programs and processes for continued safe operation of Pickering NGS until the end of 2024.

1. Organization, Management Systems and Safety Culture was reviewed as a safety factor for Pickering PSR2. Specifically, this review confirmed that the Pickering NGS organization, management system and safety culture are effective.

2. Human Factors was reviewed as a safety factor for Pickering PSR2. Specifically, this review confirmed that the various human factors that may affect the safe operation of Pickering NGS have been appropriately addressed, and are effective.

3. Safety Performance was reviewed as a safety factor for Pickering PSR2. Specifically, this review confirmed that the safety performance indicators and records of operating experience, including the evaluation of root causes of plant events, exist and are utilized.

4. OPEX and Research Findings was reviewed as a safety factor for Pickering PSR2. Specifically, this review confirmed that for Pickering NGS there is adequate feedback of relevant experience from other nuclear power plants and from findings of research, and that this is used to introduce reasonable and practicable safety improvements at the plant or in the operating organization.

5. The area of Procedures was reviewed as a safety factor for Pickering PSR2. Specifically, this review confirmed that the Pickering NGS processes for managing, implementing and adhering to operating and working procedures and for maintaining compliance with operational limits and conditions and regulatory requirements are adequate and effective and ensure plant safety.

6. Deterministic Safety Analysis was reviewed as a safety factor for Pickering PSR2. Specifically, this review confirmed that the deterministic safety analysis programs and procedures at OPG are comprehensive, resulting in a systematic and disciplined approach to identifying, prioritizing and addressing any safety analysis related issues.

7. Hazard Analysis was reviewed as a safety factor for Pickering PSR2. Specifically, this review confirmed that Pickering NGS has robust protection against internal and external hazards, taking into account the plant design, site characteristics, the actual condition of the Structures, Systems and Components (SSCs) important to safety.

8. Probabilistic Safety Assessment (PSA) was reviewed as a safety factor for Pickering PSR2. Specifically, this review has confirmed that the PSA programs and procedures at OPG are comprehensive, resulting in a systematic and disciplined approach to identifying, prioritizing and addressing safety analysis related issues.

9. Plant Design was reviewed as a safety factor for Pickering PSR2. This review confirmed, by assessment against the current licensing basis and applicable standards, requirements and practices that the physical design and documentation supports continued safe operation of Pickering NGS.

10. Equipment environmental and seismic qualifications were reviewed as a safety factor for Pickering PSR2. Specifically, this review confirmed that the Pickering NGS equipment important to safety has been properly environmentally and seismically qualified and that these qualifications are being maintained through maintenance, inspection and testing programs.

11. Actual condition of Structures, Systems and Components (SSCs) important to safety was reviewed as a safety factor for Pickering PSR2. Specifically, this review concluded that the majority of the plant's SSCs are in good condition and support safe extended station operation to the end of 2024. Recommendations for improvement have been made where required, of which many are in progress. For this life extension period, no major concerns have been identified and the SSCs Important to Safety continue to operate as per the design basis requirements.

12. Plant aging was reviewed as a safety factor for Pickering PSR2. Specifically, this review confirmed that aging aspects affecting SSCs important to safety are being effectively managed and that an effective aging management program is in place.

13. Radiation Protection was reviewed as a safety factor for Pickering PSR2. Specifically, this review has confirmed that radiation protection has been accounted for in the design and operation of Pickering NGS, and that radiation protection provisions (including design and equipment) protect workers from radiation and ensure that contamination and radiation exposures and doses to persons are monitored and controlled and maintained As Low As Reasonably Achievable (ALARA).

14. Radiological Impact on the Environment was reviewed as a safety factor for Pickering PSR2. Specifically, this review has confirmed that Pickering NGS has in place an effective program for monitoring the radiological impact of the plant on the environment, which ensures that emissions are properly controlled and are as low as reasonably achievable.

15. Emergency Planning was reviewed as a safety factor for Pickering PSR2. Specifically, this review has confirmed that OPG Nuclear has in place adequate plans, staff, facilities and equipment for dealing with emergencies. In addition, arrangements are in place for regular emergency training and exercises, and interaction and coordination with local and national authorities.
