BUSINESS CASE SUMMARY

PNGS A - Mod/Replacement of FRP Components During 2010 VBO 13 - 49285 Superseding Business Case NA44 - BCS - 34320 - 00004 - R000

RECOMMENDATION:

ONTARIOPOWER

GENERATION

We recommend a Superseding Release of \$11.7M (including \$1.8M contingency), for the PNGS A Modification/Replacement of Fiberglass Reinforced Plastic (FRP) Components During the 2010 Vacuum Building Outage (VBO) Project. The total released will be \$24.5M (including \$1.8M contingency).

The release history for this work had it moving from OM&A to Capital with change in strategy from inspect and selective replacement to full replacement. As such, the cost of the incremental costs that are now being included in this BCS were previously captured among the various contracts within the Outage. The main business objective of this project remains unchanged from the Full Release Business Case; however the BCS has been updated to include the following incremental costs required for the execution of the project that were not identified in the full release. The final project estimate includes the following costs:

- 1. Incremental scaffolding required to install the FRP piping. This was segregated from the remainder of the scaffolding requirements for the outage work program and is specific to the installation of the FRP.
- 2. Incremental Power Supplies associated with the installation of the piping.
- 3. Incremental Craning and Rigging requirements to transport/install the FRP material in the Vacuum Building.
- 4. Incremental Safety equipment required for installation of the piping due to hazardous fumes. This item was determined to be an incremental requirement late in the project due to one time use of the equipment associated with the resin environment.
- 5. Incremental resources to perform confined space monitoring duties due to the hazards created in the vacuum building due to hazardous fumes.

Items 1 -3 were discovered during a detailed review of outage scope, reviewed by Finance, and deemed to be an incremental cost of the project that satisfies the Capital eligibility requirements. The balance of the Superseding Release remains unchanged except for the updated financial figures throughout the balance of the document. The proposed scope remains unchanged as detailed in Section 4 - The Proposal. The superseding release has been developed in consultation with the Outage, Finance, Maintenance and Project organizations.

BUSINESS CASE SUMMARY

2/ BACKGROUND & ISSUES

This project is being implemented to complete modifications/repairs/replacement of FRP components located within the Vacuum Building.

The Water Spray System located in the Vacuum Building (VB) at the Pickering Nuclear Generating Station performs the pressure suppression function of the Negative Pressure Containment System (NPC) following a Loss of Coolant Accident (LOCA) or a Main Steam Line Break (MSLB) inside containment. The Vacuum Building supports both Pickering A and B stations.

The Water Spray System and the Vacuum System utilize FRP piping extensively. Degradation or aging of FRP components is being assessed and repairs have been required during past VBOs. Prior testing and analysis has concluded that the FRP components are fit for service until 2012.

There is currently an aging management program (project 49273) being executed by third party subject matter experts aimed at assessing the degradation of the material over time and gives recommendations for replacements or repairs to FRP components. Project 49273 includes testing of FRP samples removed during the 2000 VBO to determine the material properties and quantify the degradation. A series of recommendations have been developed which identify high risk FRP components as well as recommended samples to be removed to support the aging management program (reference NA44-CORR-34320-024520). The recommendations for the FRP components of the Vacuum System (SCI 34220) are being addressed by a separate project, the VB Basement Improvements Project 49278.

The higher risk components identified include the spray headers, spray plates and risers (below the EWST water line). Components considered to be low risk include the spray header T-sections, U-tubes, the Upper and Lower Down-Comers (UDCs & LDCs) and their flanges in the Upper Vacuum Chambers. Originally (at the time of Partial Release) one Riser and 1 unable to conclusively support fitness for service of the existing Risers, therefore they are planned to be replaced. Also, in One Spray Header sample is to be extracted along with two Spray Header Saddle Supports. In addition, FRP parts are required to be on hand in case more components are found to be damaged/degraded beyond repair.

There is a known issue of possible gaps forming between the Spray Plates and Spray Headers during a douse due to the differential expansion under pressure and a deteriorated glue bond. The water spray function is not compromised by this condition (reference NA44-CORR-25000-0274905), however, load testing for spray plates will be completed (by IM&CS) to verify integrity of the glue bonds, and any failed plates will require repair or replacement during the outage.

The Down-Comers have Stiffening Rings installed for reinforcement to meet the required safety factor. Two types exist, "old" Stiffening Rings (installed in 1980) and "new" Stiffening Rings (installed in 2000). The new rings were redesigned to properly bond to the pipe but the old rings will need reinforcement FRP strips or "Reinforcement Bands" installed to ensure that they do not shift out of position. Some of the old rings were reinforced during the 2000 VBO.

The Spray Header Fill Lines are used to circulate the water that forms the loop seal in the U-tubes to separate the Main and Upper Vacuum Chambers. The connections to the Spray Headers are considered to be a sub standard design and at least one connection was found to leak in the last VBO.

The vertical leg of each Spray Header Saddle Support is constructed of an FRP pipe and press-molded flange. The flange is bolted to a steel plate which is connected to a concrete beam. One of the press-molded flanges removed during the 2000 VBO was badly damaged and some of the flanges are not properly glued to the support pipe. Although the Water Spray inspection following small earthquakes. It therefore must be demonstrated that the support pipe will not dislodge from the flange under seismic loading.

The Lower Down-Comer Split Flanges, located on the EWST Floor, are potential leakage sites. Pickering B requires the water in the tank for make-up to the moderator system following a DBE coincident with failure of the Emergency Water /Power Systems. The Water Spray System is not seismically qualified and therefore these flanges cannot be relied upon to maintain the seal following a DBE. It has been proposed that seismically qualified weirs be installed around the flanges to maintain adequate water inventory in the tank, refer to NK30-CORR-71330-0279688, "Requirement for Seismic Qualifications of the

BUSINESS CASE SUMMARY

Emergency Storage Water Tank".

In addition to the modifications to be completed and samples to be extracted, repairs to FRP components may be required based on inspections completed during the outage or, as a result of "grinding" required to support various inspections.

Base Case: Not Recommended - Status Quo

If replacement materials are not procured and design packages not completed, significant extensions to the 2010 VB Outage are likely. Current fitness for service is to 2012 only, therefore a subsequent outage may also be required if the necessary repairs and modifications cannot be completed during the 2010 VBO.

Alt. 1: Recommended - Modifications & Repairs - Riser Replacement with Contingency for Major Discovery Repairs

This alternative is recommended in support of the fitness for service evaluation of the FRP components to 2024. The following is a brief summary of the scope. A detailed description can be found in Section 4, The Proposal.

- 1. Extraction and replacement of FRP samples to support the aging management program
- 2. 100% replacement of the Riser sections below a cut made just above the EWST waterline
- 3. Procurement of limited number of spare components for Spray Headers, Spray Header Saddle Supports, Upper Down-Comers, Spray Plates and 4" Vacuum System piping as well as replacement as necessary during the VBO
- 4. Replace Spray Header Fill Line Connections (modification)
- 5. Add reinforcing bands to the Upper Down-Comer Stiffening rings installed in 1980
- 6. Install Weirs around the Upper Down-Comers to ensure EWST inventory is maintained following a DBE (modification)
- 7. Complete minor repairs to FRP components as identified by in-situ inspections.

This option provides the most economical solution by completing necessary replacements/modifications and preparing for the replacement/repair of additional high risk components. The highest risk components, the risers, will be replaced as part of scope. Other components will be procured but replacement cost is to be covered by specific contingency. The positive NPV calculated assumes that a 4 day outage extension is required for riser replacement but the risk of further extension (material lead time) and the risk of a subsequent outage for further repairs is mitigated.

The Partial Release included an option with a reduced amount of contingency preparation. This option has been eliminated based on the relatively low cost compared to significant consequences of an outage extension which could be as long as the material lead time of approximately 5 months.

Alt. 2: Not Recommended - Modification and Repairs with Stainless Steel

This alternative is not recommended. Replacement of the high risk Water Spray System components with new stainless steel to reduce requirements for aging of samples, associated with determination of long term integrity of FRP components. The main reasons for rejection of this alternative are discussed below:

Some components are not possible or practical to replace with stainless steel such as the fill line connection points, the spray plates and the lower components of the saddle supports. Also, transitions between materials (FRP flanges required) would be necessary for the riser replacement in order to maintain the current VBO schedule similar to Alternative 1. Therefore FRP expertise and design would still be required, and engineering effort would be substantially increased since these

6 of Attachment 1 Tab 12

BUSINESS CASE SUMMARY

replacements would no longer be equivalent. There is also a technical/operability risk introduced at the required mechanical joints due to the possibility of main to upper chamber leakage. To eliminate this risk, complete riser replacement would be required (up to flange in the upper chamber). The schedule would be substantially increased due to multiple field welds required for installation.

BUSINESS CASE SUMMARY

4/ THE PROPOSAL

There is significant risk of outage extensions due to as-found condition of FRP components. This project will ensure readiness to repair or replace high risk FRP components as well as support the aging management program to ensure fitness for service to at least 2024.

The following is the proposed scope for the recommended alternative (Alt. 1):

Risers

- (a) Procure, Remove and Replace all 14 (section below a cut made above the EWST water line)
- (b) Procure 1 additional section (similar to the replacement components) for aging management
- (c) Procure 1 extra 10' length of riser pipe for additional parallel plate tests as requested by the aging management program

Upper Down-Comers

- (a) Procure, Remove and Replace 2 sections (section below a cut made above the EWST water line) for aging management
- (b) Procure and Replace 1 additional section (dependent on inspection results, installation costs included in contingency)
- (c) Procure 1 extra Upper Down-Comer to be used for aging management (no installation involved)

Spray Headers

- (a) Procure, Remove and Replace 1 section for aging management
- (b) Procure and Replace 1 additional section (dependent on inspection results, installation costs included in contingency)
- (c) Procure 1 extra header section to be used for aging management (no installation involved)

Spray Plates

(a) Procure and replace 100 new Spray Plates (dependent on inspection results, installation costs included in contingency)

Spray Header Saddle Supports

- (a) Procure, Remove and Replace 2 supports (from under the Spray Header section removed) for aging management
- (b) Procure and Replace 2 additional supports (dependent on inspection results, installation included in contingency)
- (c) Procure 2 extra Saddle Supports for aging management (no installation involved)
- (d) Procure 51 additional replacement parts for the lower flange. Installation costs are covered under contingency.

4" Vacuum System Piping in the Main Volume

(a) Procure and Replace up to 20 feet of pipe and 8 elbows (dependent on inspection results)

Spray Header Fill Line Connections

(a) Modify/Replace all 28 fill line connections via the modification process

Stiffening Rings

(a) Install Reinforcing bands on old Stiffening Rings not previously reinforced.

Lower Down-Comer Split Flanges

(a) Install Weirs around 14 Lower Down-Comer Split Flanges (around Upper Down-Comers), via the modification process

This release also includes the execution support work directly required to complete the above scope of work.

This Full Release will include:

Project Management Services
Completion of Detailed Design
Installation Contracts Awarded
QA/QC Support Contracts Awarded
Installation, Commissioning, AFS and Closeout

Filed: 2013-09-27 EB-2013-0321

Page: Ex802120

Attachment 1 Tab

BUSINESS CASE SUMMARY

5/ QUALITATIVE FACTORS

The following project benefits have not been quantified in the Economic Analysis but are significant and therefore worth noting.

This project will procure samples of new material and extract/replace samples from the VB. These are required to support future aging management.

Pickering B requires a supply of water from the EWST for moderator makeup following a seismic event. Installation of seismically qualified weirs around the Lower Down-Comer Split flanges will ensure this supply is available. Currently license.

The risk of disengagement or excessive leakage from the Spray Header Fill Line connections will be eliminated through a modification.

Spare Spray Header sections, Spray Header Saddle Supports, Spray Plates, and 4" FRP pipe, will be available and replaced if necessary, contributing to fitness for service.

All of the repairs/replacements/modifications identified in this BCS, support fitness for service evaluation for the Vacuum Building Water Spray System until 2024.

BUSINESS CASE SUMMARY

Attachment 1 Tab 12

Appendix "C"

Financial Model - Assumptions

Financial Assumptions:

Discount Rate	70/	0.15				
	170	Cost Escalation (yr)	None	SR & D Opportunity	No	٦
Progress Payments	N/A	Foreign Currency	No			\dashv
Income Tax Rate	<u> </u>		INU	Retainer Fee	No	
	Generation	PST		Interest Rate (Capital)	6%	7
Depreciation Rate (Capital)	N/A	Leasing	NI/A		076	_
Comments:	10/1	Leasing	N/A	Indexed Priced Contract	N/A	

Project Cost Estimate:

Design Complete	100%	Quality of Cational	pa, s		
		Quality of Estimate	Release + 15% to - 10%	3rd Party Estimate	No
Reviewed by Sponsor	Yes	OPEX used	Yes	Lessons Learned	Yes
Similar Projects	Yes	Budgetary Quote(s)	Yes		
Cost Sharing	Yes	Contracts in place		First Unit Actual Used	Not unitized
Fixed Price Contract			Yes	Competitive Bid	Yes
	Yes	Fee for Service		Firm Vendor Proposal	Yes
Comments:					1 169

Rationale for Cost Classification:

Switch from OM&A to Capital - Replacement of Water Spray system FRP components which have significant risk of not being fit for service until the next VBO.

Generation Plan Assumptions:

Station	Unit	Ε()L	MW	Capacity	Planned Outages for Project Work (eg P1071)
Pickering A	1	N/A	N/A			Plained Outages for Project Work (eg P1071)
r ickering A	4	N/A	N/A	513	85%	
	5	N/A	N/A			
Dickering D	6	N/A	N/A			
Pickering B	7	N/A	N/A	516	85%	
	8	N/A	N/A			
	1	N/A	N/A			
Darlington	2	N/A	N/A			
Darlington –	3	N/A	N/A	N/A	N/A	
	4	N/A	N/A			

Comments:

The NPV calculations are all based on the risk of lost generation due to an outage extension in 2010 VBO or a subsequent outage in 2012 (when FRP fitness for service expires). The end of life of all 6 remaining Pickering units therefore does not factor into the calculation.
